Unified Extensible Firmware Interface (UEFI) Specification

Release 2.9 Errata A

UEFI Forum, Inc.

Aug 29, 2022

CONTENTS

Acknowledgments

The material contained herein is not a license, either expressly or impliedly, to any intellectual property owned or controlled by any of the authors or developers of this material or to any contribution thereto. The material contained herein is provided on an "AS IS" basis and, to the maximum extent permitted by applicable law, this information is provided AS IS AND WITH ALL FAULTS, and the authors and developers of this material hereby disclaim all other warranties and conditions, either express, implied or statutory, including, but not limited to, any (if any) implied warranties, duties or conditions of merchantability, of fitness for a particular purpose, of accuracy or completeness of responses, of results, of workmanlike effort, of lack of viruses and of lack of negligence, all with regard to this material and any contribution thereto. Designers must not rely on the absence or characteristics of any features or instructions marked "reserved" or "undefined." The Unified EFI Forum, Inc. reserves any features or instructions so marked for future definition and shall have no responsibility whatsoever for conflicts or incompatibilities arising from future changes to them. ALSO, THERE IS NO WARRANTY OR CONDITION OF TITLE, QUIET ENJOYMENT, QUIET POSSESSION, CORRESPONDENCE TO DESCRIPTION OR NON-INFRINGEMENT WITH REGARD TO THE SPECIFICATION AND ANY CONTRIBUTION THERETO.

IN NO EVENT WILL ANY AUTHOR OR DEVELOPER OF THIS MATERIAL OR ANY CONTRIBUTION THERETO BE LIABLE TO ANY OTHER PARTY FOR THE COST OF PROCURING SUBSTITUTE GOODS OR SERVICES, LOST PROFITS, LOSS OF USE, LOSS OF DATA, OR ANY INCIDENTAL, CONSEQUENTIAL, DIRECT, INDIRECT, OR SPECIAL DAMAGES WHETHER UNDER CONTRACT, TORT, WARRANTY, OR OTHERWISE, ARISING IN ANY WAY OUT OF THIS OR ANY OTHER AGREEMENT RELATING TO THIS DOCUMENT, WHETHER OR NOT SUCH PARTY HAD ADVANCE NOTICE OF THE POSSIBILITY OF SUCH DAMAGES.

Revision History

Table 1: **Changes in this release**

Revision	Mantis # / Description	Affected Content
2.9A	2225 - Clarify the specification requirements around processing Boot#### variable	Section 3.1.7, Table 3.3, Section 7.1.2
2.9A	2227 - Clarify NVMe device path EUI-64 byte order	Section 10.3.4.21
2.9A	2235 - Clarify EFI_LOAD_OPTION.FilePathList[] device path definition	Section 3.1.3
2.9A	2243 - Removing old references to Wired for Management (WfM)	Section 3.5.2.1, Section 7.3.1, Table 24.13, *Referenced Specifications*, *Appendix R — Glossary*
2.9A	2249 - Cleanup of the SI & Binary Prefixes section	Section 1.9.8
2.9A	2251 - Clarification of DevicePath examples using 0xFF for End of HW DP	Section 10.3.4.4, Table 12.20, Table 14.18, Table 15.4, *Legacy Floppy*
2.9A	2252 - Clarify OS dependency on UEFI vs PI interfaces	Section 1.4
2.9A	2263 - CXL CPER updates	Table N.41
2.9A	2266 - Code First - Image Execution Table - clarify revocations of hashes	Section 32.4.2
2.9A	2270 - Add “CPER” acronym to Appendix N	*Appendix N - Common Platform Error Record (CPER)*
2.9A	2277 - Code first - Uart() UEFI DevicePath binary/text confusion issue	Section 10.6.1.6
2.9A	2286 - Section header for *CHAP (using RADIUS) Authentication Node*	Section 32.1.6
2.9A	2306 - Define Arm CPER Processor Error Types	*ARM Processor Error Information Structure*
2.9A	2311 - Define the DevicePath argument from LoadImage as optional	Section 7.4.1
2.9A	2327 - Correcting subtype value for *REST Service Device Path*	Section 10.3.4.31, Table 10.64
2.9A	2330 - Principle of Inclusive Terminology statement	Section 1.1
2.9A	2336 - Feedback on UEFI 2.10 draft	*sections throughout*
2.9A	2342 - GetHealthStatus: Make the statement and table consistent for EFI_UNSUPPORTED for Controller Handle Null case	Section 11.10.2

Changes in previous releases

Revision	Mantis # - Description	Release Date
2.9	1866 GetInfo() of Adapter Information Protocol should have a provision for IHV to return no data	March 2021
2.9	1982 Clarify the PKCS#7 SignedData structure of EFI_VARIABLE_AUTHENTICATION	March 2021
2.9	1986 Need a mechanism using which browser to exit out of IHV formset silently without any popup	March 2021
2.9	1989 NVDIMM SPA Location Cookie	March 2021
2.9	2024 CXL CPER Records	March 2021
2.9	2042 New Event Group EFI_EVENT_GROUP_AFTER_READY_TO_BOOT	March 2021

continues on next page

Table 2 – continued from previous page

2.9	2043 New Event Group EFI_EVENT_GROUP_BEFORE_EXIT_BOOT_SERVICES	March 2021
2.9	2046 Add support for Key 14 & 56 for Japanese keyboard layout	March 2021
2.9	2053 Figure/Table Numbers are Duplicated in Appendices	March 2021
2.9	2062 Table numbering to restart for each chapter	March 2021
2.9	2065 CXL proposal for CDAT table extraction from devices	March 2021
2.9	2093 UpdateCapsule ScatterGatherList cache maintenance	March 2021
2.9	2129 Add DTB Configuration Table standard GUID	March 2021
2.9	2131 Clarify Console requirements	March 2021
2.9	2134 Introduce unaccepted memory type	March 2021
2.9	2155 Typo in Arm Processor CPER Error Section	March 2021
2.9	2167 CPER for CXL Component Events	March 2021
2.9	2185 Declaration for UEFI 2.9 specification in the System Table	March 2021
2.9	2190 Misc. spec review feedback	March 2021
2.9	2199 EFI_IMAGE_EXECUTION_INFO_TABLE references	March 2021
2.9	2200 Config tables references from section 4.6	March 2021
2.9	2204 Typo in GUID definition for EFI_MANAGED_NETWORK_SERVICE_BINDING_PROTOCOL	March 2021
2.9	2212 Incorrect cross reference to User Information Table	March 2021
2.8 C	2117 - E FI_BROWSER_ACTION_REQUEST_RECONNECT - perform the action when user exits out of formset	Jan. 2021
2.8 C	2139 Update RISC-V UEFI corresponding spec to align with latest RISC-V spec	Jan. 2021
2.8 C	2155 Typo in Arm Processor CPER Error Section	Jan. 2021
2.8 C	2158 EFI_DRIVE R_HEALTH_PROTOCOL.GetHealthStatus() - Driver not managing any controller	Jan. 2021
2.8 C	2172 Revise EFI_REDFISH_DICOVER_PROTOCOL definitions to match the implementation.	Jan. 2021
2.8 C	2173 Question on EFI_CAPSULE_HEADER Flags definition	Jan. 2021
2.8 C	2184 FI_BOOT_MANAGER_POLICY_PROTOCOL typos	Jan. 2021
2.8 C	2190 EFI_SUCCESS misspelled in five places	Jan. 2021
2.8 B	1926 update: corrected EFI_SYSTEM_TABLE entries from 2_8 to 2_80	May 2020
2.8 B	1935 update: removed a space from several references to the EFI_JSON_CAPSULE_ID_GUID	May 2020
2.8 B	2073 Modify definition of “DPA” for use with CXL based devices	May 2020
2.8 B	2074 Memory Range typo	May 2020
2.8 B	2080 Typo in N.2.2 Section Descriptor Table 56	May 2020
2.8 B	2083 Typo in guid definition of CCIX PER Log Error Section	May 2020
2.8 B	2088 Clarifications on caller-freed buffers	May 2020
2.8 B	2091 Inconsistency in description of EFI_FIRMWARE_MANAGEMENT_CAPSULE_IMAGE_HEADER structure	May 2020
2.8 B	2092 Typo in definition of PEI Notification type in Table 269. Error record header	May 2020
2.8 B	2095 PCI I/O attribute typos in section 14.4 “EFI PCI I/O Protocol”	May 2020
2.8 B	UEFI Runtime Service Table correction	May 2020
2.8 B	2096 Typo in definition of EFI_JSON_CONFIG_DATA_ITEM	May 2020

continues on next page

Table 2 – continued from previous page

2.8 A	1970 Security Command Protocol change for OPAL RAID devices	February 2020
2.8 A	1998 Update RISC-V related spec	February 2020
2.8 A	2000 JSON Capsule clarification	February 2020
2.8 A	2002 Memory allocations between ExitBootServices calls	February 2020
2.8 A	2009 DMTF references in UEFI spec	February 2020
2.8 A	2013 Correct EFI _BOOT_SERVICES.DisconnectController contradicting info in Description	February 2020
2.8 A	2018 EFI_EDID_OVERRIDE_PROTOCOL_GET_EDID should take an EFI_HANDLE as ChildHandle	February 2020
2.8 A	2020 EF I_LOADED_IMAGE_PROTOCOL.LoadOptions does not mention it is related to Load Options.	February 2020
2.8 A	2025 Capsule Depex Length Declaration	February 2020
2.8 A	2026 FMP Capsule Image Header extension	February 2020
2.8 A	2029 Add missing GUIDs in Appendix N	February 2020
2.8 A	2030 Fix spec index to show the Appendix chapters	February 2020
2.8 A	2034 Depex added description	February 2020
2.8 A	2035 Fix OUT parameters marked as IN OUT	February 2020
2.8 A	2036 SetVariable errata: clarify that in-place variable update is supported	February 2020
2.8 A	2038 Configuration Tables Errata	February 2020
2.8 A	2041 EFI_EVENT_GROUP_EXIT_BOOT_SERVICES Errata	February 2020
2.8 A	2050 Incomplete list of EFI_SERVICE_BINDING_PROTOCOL protocols	February 2020
2.8 A	2049 RuntimeServicesSupported EFI variable should be a config table	February 2020
2.8 A	2051 Typo in Table - CPER IA32/X64 Bus Check Structure	February 2020
2.8 A	2053 Figure/Table Numbers are Duplicated in Appendices	February 2020
2.8	1832 Extend SERIAL_IO with DeviceTypeGuid	March 2019
2.8	1834 UEFI REST EX Protocol	March 2019
2.8	1853 Adding support for a REST style formset	March 2019
2.8	1858 New Device Path for bootable NVDIMM namespaces	March 2019
2.8	1861 New EFI_MEMORY_RANGE_CAPSULE Descriptor	March 2019
2.8	1866 GetInfo() of Adapter Information Protocol should have a provision for IHV to return no data	March 2019
2.8	1872 Peripheral-attached Memory	March 2019
2.8	1876 Remove the EBC support requirement	March 2019
2.8	1879 Clarification of REST (EX) protocol	March 2019
2.8	1908 Update of uncommitted data in the FOROM_OPEN callback	March 2019
2.8	1919 Memory Cryptography Attribute	March 2019
2.8	1920 Redfish Discover Protocol	March 2019
2.8	1921 HTTPS hostname validation	March 2019
2.8	1924 Update to EF I_REST_EX_PROTOCOL.AsyncSendReceive	March 2019
2.8	1925 Clarify requirement of REST related protocols	March 2019
2.8	1926 New UEFI Spec Revision –> 2.8	March 2019
2.8	1935 UEFI JSON Capsule Support	March 2019
2.8	1936 ResetSystem - support ResetData for all status scenarios.	March 2019
2.8	1937 Behavior of default values	March 2019
2.8	1941 New EFI REST JSON Structure Protocol	March 2019
2.8	1942 Adding dependency expression capability into FMP type capsules	March 2019

continues on next page

Table 2 – continued from previous page

2.8	1947 Keyword strings of Configuration Keyword Handler Protocol Enhancements	March 2019
2.8	1953 Add document version# conventions	March 2019
2.8	1954 set (*Attributes) when GetVariable() returns EFI_BUFFER_TOO_SMALL and Attributes is non-NULL	March 2019
2.8	1956 Platform to honor ActionRequest for Action changing	March 2019
2.8	1961 Add EFI_UNSUPPORTED to EFI_RUNTIME_SERVICES calls	March 2019
2.8	1966 Add new capsule processing error codes	March 2019
2.8	1974 Add new CCIX PER Log Error Section to appendix	March 2019
2.8	1996 Firmware Processing of the Capsule Identified by EFI_JSON_CAPSULE_ID_GUID	March 2019
2.7B	1773 Clarify The EFI System Table entry for capsule image	March 2019
2.7B	1801 ExtractConfig() format may change when called multiple times	March 2019
2.7B	1835 Misleading / unclear statement about EFI-bootability of UDF media	March 2019
2.7B	1838 RGB/BGR Contradiction in 2.7 GOP	March 2019
2.7B	1841 BluetoothLE ECR - support autoreconnect	March 2019
2.7B	1842 BluetoothLE ECR - Add missing ConnectionCompleteCallback	March 2019
2.7B	1843 HTTP Example Code Update	March 2019
2.7B	1844 Replace obsoleted RFC number with new number for TCP	March 2019
2.7B	1845 Clarification on AIP types “Network boot” and “SAN MAC Address”	March 2019
2.7B	1846 EFI_LOAD_FILE2 requirement	March 2019
2.7B	1865 Adding clarification in EFI_NOT_READY for ReadKeyStrokeEx()	March 2019
2.7B	1869 Clarify FMP buffer too small behavior	March 2019
2.7B	1874 Add RFC3021 to reference in uefi.org	March 2019
2.7B	1875 Clarify platform specific elements in chapter 2.6.2	March 2019
2.7B	1878 Errata - Make DHCP server optional for HTTP boot	March 2019
2.7B	1880 Arm binding EL2 register state clarification	March 2019
2.7B	1890 EfiMemoryMappedIO Usage Clarification	March 2019
2.7B	1897 Clarification on mapping of UEFI memory attributes to ARM memory types and paging attributes	March 2019
2.7B	1899 Errata: Clarify EFI_INVALID_PARAMETER for FMP->GetImageInfo()	March 2019
2.7B	1901 GPT Protective MBR description	March 2019
2.7B	1902 CapsuleImageSize Clarification	March 2019
2.7B	1903 Root Directory File Name	March 2019
2.7B	1906 ACPI Table Pointer Installation	March 2019
2.7B	1908 Update of uncommitted data in the FOROM_OPEN callback	March 2019
2.7B	1923 Syntax error in EFI iSCSI Initiator Name Protocol	March 2019
2.7B	1957 Request to add status code EFI_DEVICE_ERROR for ExtractConfig	March 2019
2.7B	1964 Print disclaimer for all future UEFI specs	March 2019
2.7B	1987 incorrect VLAN_CONFIG_SET function definition	March 2019
2.7A	1830 Label Protocol - EFI_NVDIMM_LABEL_FLAGS_LOCAL definition needs to be updated	August 2017

continues on next page

Table 2 – continued from previous page

2.7A	1829 Label Protocol Section - Missing define for EFI_NVDIMM_LABEL_FLAGS_UPDATING	August 2017
2.7A	1823 Modifications to the examples of the PCI Option ROM image combinations	August 2017
2.7A	1822 UEFI 2.7 Organization chapter duplicated	August 2017
2.7A	1821 Modify the requirement to enable PCI Bus Mastering	August 2017
2.7A	1817 NVDIMM Label Protocol - SetCookie SerialNumber needs to be UINT32 NOT UINT64	August 2017
2.7A	1816 Clarification of Using HttpConfigData in HTTP protocol	August 2017
2.7A	1815 OpenProtocol() / EFI_ALREADY_STARTED should output existent Interface	August 2017
2.7A	1808 Clarification of using option 43 in PXE v2.1	August 2017
2.7	1779 Adjusting UEFI version to UEFI 2.7	April 2017
2.7	1771BluetoothLE minor fix	April 2017
2.7	1762 UEFI UFS DEVICECONFIG Protocol	April 2017
2.7	1751 Update DNS Device Path	April 2017
2.7	1750 Add new data type to EFI Supplicant Protocol	April 2017
2.7	1745 NVDIMM Label Protocol	April 2017
2.7	1744 NVDIMMBlock Translation Table (BTT) Protocol {NewChapter}	April 2017
2.7	1730 HII Popup Protocol	April 2017
2.7	1726 Host and I/O defense	April 2017
2.7	1720 Have Partition driver publish addition information for MBR/GPT partition types.	April 2017
2.7	1719 Add EFI HTTP Boot Callback Protocol	April 2017
2.7	1718 Allow SetData to clear configuration in Ip4Config2/Ip6Config Protocol	April 2017
2.7	1716 Add BluetoothLE ECR	April 2017
2.7	1711 Firmware Error Record Update	April 2017
2.7	1707 Clarification of Private Authenticated Variables	April 2017
2.7	1701 Add wildcard support to RegisterKeyNotify	April 2017
2.7	1690 Reset Notification Protocol Update	April 2017
2.7	1689 Secure Boot with Externally Managed Configuration	April 2017
2.7	1685 Key Management Services (KMS) Protocol Enhancement	April 2017
2.7	1672 UEFI Variable Enhancements	April 2017
2.7	1654 New AIP Information block for wireless NIC	April 2017
2.7	1652 Add DNS device path node	April 2017
2.7	1647 UEFI binding for RISC-V	April 2017
2.7	1641 Simplify SecureBoot Revocation and Usage of VerifySignature	April 2017
2.7	1641 Simplify Secure Boot Revocation and Usage of VerifySignature	April 2017
2.7	1627 Support ASCII RegEx Patterns in EFI_REGULAR_EXPRESSION_PROTOCOL	April 2017
2.7	1627 EFI regular expression syntax type definitions	April 2017
2.7	1623 New EFI_HTTP_STATUS_CODE enum for 308 Permanent Redirect	April 2017
2.7	1623 New EFI_HTTP_STATUS_CODE enum for 308 Permanent Redirect	April 2017
2.6B	1772 Clarify EFI_NOT_READY in Media State of AIP	April 2017

continues on next page

Table 2 – continued from previous page

2.6B	1767 Incorrect structure definition for EFI_IFR_RESET_BUTTON_OP	April 2017
2.6B	1742 Clairfy PK enrolling in user mode	April 2017
2.6B	1741 The memory map returnedByBS->GetMemoryMap() mayContain impossible values.	April 2017
2.6B	1739 typos -Broken references link.	April 2017
2.6B	1729Cleanup of ACPI 2.0 references in UEFI spec	April 2017
2.6B	1708 Typos in Imge Decode and Image Ex Protocols	April 2017
2.6B	1700 Align ACPI descriptor definitions in PCI I/O and PCI Root-Bridge I/O	April 2017
2.6B	1698 Update to Mantis 1613 - GetNextVariable	April 2017
2.6B	1691 Remove/Deprecate SMM Communication ACPI Table	April 2017
2.6B	1682 HII Protocol StatusCodes	April 2017
2.6B	1678 Simplify the ACPI Table GUID declarations	April 2017
2.6B	1675 section 30.5.1 typo	April 2017
2.6B	1668 Duplicate GUID issue - mustChange the Image Decoder Protocol GUID	April 2017
2.6B	1655 HTTP errata inConfigure()	April 2017
2.6B	1653 Incorrect errorCode value in MTFTP6	April 2017
2.6B	1634 Update to the EFI_SIMPLE_TEXT_INPUT_PROTOCOL TPL restriction	April 2017
2.6B	1629 Errata in GetVariable description	April 2017
2.6B	1625 Clarification of HTTPBoot wire protocol “HTTPClient” VendorClass Option	April 2017
2.6B	1624 Fix spelling typo in EFI_HTTP_STATUS_CODE	April 2017
2.6B	1613 GetNextVariableName Errata	April 2017
2.6B	1612 ResetSystem Errata	April 2017
2.6B	1609 UEFI Errata - Address Security problems in the Pkcs7Verify Protocol	April 2017
2.6B	1608 Enhance EFI_IFR_NUMERIC (Step)	April 2017
2.6B	1586 Errors in appendix N for ARM ProcessorContext Information	April 2017
2.6B	1584 WIFI errata	April 2017
2.6B	1580 Correct some typos	April 2017
2.6B	1559 Clarify return value for NULL pointer in LocateProtocol() API	April 2017
2.6B	1557 secureBoot and auth variable errata	April 2017
2.6B	1556 HTTPv6Boot DHCP Options Errata	April 2017
2.6B	1555 USB Function port protocol errata	April 2017
2.6B	1554 fix to ecr 1539	April 2017
2.6B	1553 os recoveryBoot option errata	April 2017
2.6B	1551 EFIBluetoothConfiguration Protocol Errata	April 2017
2.6B	1550 Replace FTP4 dataCallback pointer-to-function-pointer with regular function pointer	April 2017
2.6A	SameContent as version 2.6,But with the Adobe “accessibility” feature activated so text-to-speech will work.	December 2016
2.6	1548ClarifyBoot procedure when file name is absent2.	January, 2016
2.6	1547Clarify requirements for setting the PK variable.	January, 2016
2.6	1544 DNS lookup API spelling	January, 2016
2.6	1543 ip4/6Config policy errata/2.6 update	January, 2016
2.6	1542 UEFI 2.6 supplicant errata	January, 2016

continues on next page

Table 2 – continued from previous page

2.6	1539 New EFI_HTTP_ERROR StatusCode	December, 2015
2.6	1538 UEFI TLS errata	December, 2015
2.6	1536 UEFI 2.6 Errata : IMAGE EX Protocol and EFI HII Image Decoder protocol Errata	December, 2015
2.6	1534 EditorialComments against 2.6 Final Draft	December, 2015
2.6	1533Bugs in the HTTP usage example	December, 2015
2.6	1523Comments against 2.6 Draft	December, 2015
2.6	1522 AArch64Bindings AlignmentBit errata	December, 2015
2.6	1521Comment against UEFI.next draft - M1479	December, 2015
2.6	1519 Version for the next UEFI spec is…	December, 2015
2.6	1518Comments against 2.6 Draft	December, 2015
2.6	1516 EditorialComments against 2.6 Draft	December, 2015
2.6	1509 EFI_PLATFO RM_TO_DRIVER_CONFIGURATION_PROTOCOL Response to unsupported ParameterTypeGuid	December, 2015
2.6	1508 Lack of flexibility and realism in exception levelChoice whenCalling runtime services	December, 2015
2.6	1507 Insufficient qualification of page attributes for AArch64	December, 2015
2.6	1502 PCI IO Define how to use the Address Translation Offset for systems that are not mapped 1:1	November, 2015
2.6	1501 Define the usage of the “Address Space Granularity” field is defined in the PCI Root IO	November, 2015
2.6	1496Bad table reference in 13.2 EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.Configuration()	November, 2015
2.6	1494 Errata against UEFI 2.5 Properties Table	November, 2015
2.6	1493 Updates to the SD_MMC_PASS_THRU interface	November, 2015
2.6	1492 wireless macConnection protocol II errata	November, 2015
2.6	1491 supplicant errata	November, 2015
2.6	1480 Refine Progress description in EFI_KEYWORD_HANDLER_PROTOCOL	November, 2015
2.6	1479 UEFI Properties TableClarification	November, 2015
2.6	1471 SD/eMMC PassThru Protocol update (follow up to mantis 1376)	November, 2015
2.6	1467 New API - EFI_ WIRELESS_MAC_CONNECTION_II_PROTOCOL	November, 2015
2.6	1466 UEFI Ram disk protocol	November, 2015
2.6	1452 Minor edits to 0001409	November, 2015
2.6	1414 Generalisation ofCommunication method in Appendix O	November, 2015
2.6	1409 EFI HII ImageEX protocol and EFI HII Image Decoder protocols	November, 2015
2.6	1408 EFI HII Font EX protocol and EFI HII Font Glyph Generator protocols	November, 2015
2.6	1402 Add EFI_BROWSER_ACTION_SUBMITTED	November, 2015
2.6	1383 Adding an EraseBlocks() function to a new protocol	November, 2015
2.6	1376 SD/eMMC PassThru Protocol	November, 2015
2.6	1357 ARMCPER extensions	November, 2015
2.5A	1481 new networkConfig2 protocol data structure has a magic number	October 2015
2.5A	1477 AllowCloseEvent toBeCalled within the Notification Function	October 2015
2.5A	1476 Update to Indicate thatCloseEvent UnregistersCorresponding Protocol Notification Registrations	October 2015

continues on next page

Table 2 – continued from previous page

2.5A	1472 ATA Pass Thru Errata	October 2015
2.5A	1469 UNDI Errata - add more statistics	October 2015
2.5A	1468 Errata on UEFI Supplicant protocol	October 2015
2.5A	1451 Memory MapConsistency	October 2015
2.5A	1441 UEFI2.5A – UNDI ProtocolClarification	October 2015
2.5A	1426 UEFI 2.5 typo	October 2015
2.5A	1424 Incorrect link in Section 22.1 FMP GetImageInfo()	October 2015
2.5A	1421 Misc HTTP API typos	October 2015
2.5A	1420 Get NextHighMonotonicCountClarification	October 2015
2.5A	1419 Supplicant protocol using same GUID as TLS protocol	October 2015
2.5A	1418 Inconsistent issues in DNS	October 2015
2.5A	1417 Add HttpMethodMax to EFI_HTTP_METHOD enum	October 2015
2.5A	1410Clarifications in appendix O	October 2015
2.5A	1407 Networking errata - EFI_HTTP_STATUS typos	October 2015
2.5A	1405 Errata in table 271 in Appendix O	October 2015
2.5A	1399 Clarification for EFI_BROWSER_ACTION_ REQUEST_RECONNECT	October 2015
2.5A	1398 Errata update to the runtime GetVariable operation documentation	October 2015
2.5A	1388 Missed memory type fixes	October 2015
2.5A	1381 Remove informativeContent in 12.6.1	October 2015
2.5A	1365 7.4 Virtual Memory Services lists Section 2.3.2 through Section 2.3.4. incorrectly	October 2015
2.5A	1363 Short form URI device path	October 2015
2.5A	1209 UEFI networking APIChapter 2.6 requirements errors	October 2015
2.5A		October 2015
2.5	1364 Extend supplicant data type for EAP	April, 2015
2.5	1362 HTTPBoot typos/bugs	April, 2015
2.5	1360 Vendor Range for UEFI memory Types	April, 2015
2.5	1358 v2.5 amendment and v2.4 errata (missed implementation of Mantis 1089)	April, 2015
2.5	1353 SATA Device Path Node Errata	April, 2015
2.5	1352 Errata for 1263 and 1227	
2.5	1350 Keyword Strings Errata	April, 2015
2.5	1348 ERRATA - Section 10.12 EFI _ADAPTER_INFORMATION_PROTOCOLCustom Types	April, 2015
2.5	1347Boot Manager Policy Errata	April, 2015
2.5	1346 Mantis 1288 Errata	April, 2015
2.5	1345 EFI_USB2_HC_PROTOCOL Errata	April, 2015
2.5	1342 DNS6 - friendly amendment for reviewBy USWG	April, 2015
2.5	1341 DNS4 - friendly amendment toBe reviewedBy USWG	April, 2015
2.5	1339 Errata in section 7.2.3.2 Hardware Error Record Variables	April, 2015
2.5	1309 Disallow EFI_VARIABLE_AUTHENTICATION from SecureBoot Policy Variables	April, 2015
2.5	1308 Fix typo's found in the final/published UEFI 2.4 ErrataB spec	February, 2015
2.5	1304 Add IMA GE_UPDATABLE_VALID_WITH_VENDOR_CODE to FMPCheck image	February, 2015
2.5	1303 Update the UEFI version to reflect new revision	February, 2015
2.5	1288 The Macro definitionConflict in EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL.SetAttribute() in UEFI 2.4B	February, 2015

Table 2 – continued from previous page

2.5	1287 Errata: EFI Driver Supported EFI Version not matching the spec revision	February, 2015
2.5	1269Configuration Routing Protocol andConfiguration String Updates	February, 2015
2.5	1268 RAM Disk UEFI Device Path Node	February, 2015
2.5	1266 UEFI.Next Feature - IP_CONFIG2 Protocol	February, 2015
2.5	1263Customized Deployment of SecureBoot	February, 2015
2.5	1257Correct the typedef definitions for EFI_BOOT_SERVICES/EFI_RUNTIME_SERVICES–Reiterate	February, 2015
2.5	1255 UFS Device Path Node Length	February, 2015
2.5	1254 SD Device Path	February, 2015
2.5	1251 EFI_REGULAR_EXPRESSION_PROTOCOL and EFI_IFR_MATCH2 HII op-code	February, 2015
2.5	1244 sections of the spec mis-arranged	February, 2015
2.5	1234 UEFI.Next feature - SmartCard edge protocol	February, 2015
2.5	1227 UEFI.Next feature - Platform recovery	February, 2015
2.5	1224 UEFI.Next - Adding support for No executable data areas	February, 2015
2.5	1223 UEFI.Next networking features -Chapter 2.6 requirements	February, 2015
2.5	1222 UEFI.Next feature -BMC/Service Processor Device Path	February, 2015
2.5	1221 UEFI.Next feature - REST Protocol	February, 2015
2.5	1220 UEFI.Next feature -Bluetooth	February, 2015
2.5	1219 UEFI.Next Feature - UEFI TLS API	February, 2015
2.5	1218 UEFI.Next feature - EAP2 Protocol	February, 2015
2.5	1217 UEFI.Next feature - WIFI support	February, 2015
2.5	1216 UEFI.next feature - DNS version 6	February, 2015
2.5	1215 UEFI.Next feature - DNS version 4	February, 2015
2.5	1214 UEFI.Next feature - HTTPBoot	February, 2015
2.5	1213 UEFI.Next feature - HTTP helper API	February, 2015
2.5	1212 UEFI.Next feature - HTTP API	February, 2015
2.5	1204 new UEFI USB Function I/O Protocol addition to the UEFI spec	February, 2015
2.5	1201 Exposing Memory Redundancy to OSPM	February, 2015
2.5	1199 Add NVM Express Pass Thru Protocol	February, 2015
2.5	1191 Add new SMBIOS3_TABLE_GUID in EFI_CONFIGURATION_TABLE	February, 2015
2.5	1186 AArch64BindingClarifications and errata	February, 2015
2.5	1183 New Protocol with 2 Function for PKCS7 Signature Verification Services	February, 2015
2.5	1174 errata - Error in EFI_IFR_PASSWORD logic flowchart	February, 2015
2.5	1167 Persistent Memory Type support	February, 2015
2.5	1166 hash 2 protocol errata	February, 2015
2.5	1163 InlineCryptographic Interface Protocol proposal	February, 2015
2.5	1159 Proposal for System Prep Applications	February, 2015
2.5	1158 errata -Boot managerClarification	February, 2015
2.5	1147–REDACT	February, 2015
2.5	1121 IPV6 support from UNDI	February, 2015
2.5	1109 SmartCard Reader	February, 2015
2.5	1103 Longer term NewCPER Memory Section	February, 2015
2.5	1091Clarification of handle to host FMP	February, 2015
2.5	1090 ESRT: EFI System Resource Table andComponent firmware updates	February, 2015

Table 2 – continued from previous page

2.5	1071 New EFI_HASH2_PROTOCOL	February, 2015
2.4C	1308 Fix typo's found in the final/published UEFI 2.4 ErrataB spec	January 2015
2.4C	1287 Errata: EFI Driver Supported EFI Version not matching the spec revision	January 2015
2.4C	1257Correct the typedef definitions for EFI__BOOT_SERVICES/EFI_RUNTIME_SERVICES	January 2015
2.4C	1244 sections of the spec misarranged	January 2015
2.4C	1211 EFI_LOAD_OPTION Definition	January 2015
2.4C	1209 Errata - UEFI networking APIChapter 2.6 requirements	January 2015
2.4C	1205 Errata for Hii Set item	January 2015
2.4C	1200 Universal Flash Storage (UFS) Device Path	January 2015
2.4C	1198 EFI_ ATA_PASS_THRU_PROTOCOLClarification	January 2015
2.4C	1194 Add EFI_IFR_FLAG_RECONNECT_REQUIRED	January 2015
2.4C	1192Cleanup GUID formatting issues	January 2015
2.4C	1186 AArch64BindingClarifications and errata	January 2015
2.4C	1185 errata - tcp api	January 2015
2.4C	1184 errata - snp modeClarification	January 2015
2.4C	1182 Errata - UEFI URI Device path issue	January 2015
2.4C	1174 errata - Error in EFI_IFR_PASSWORD logic flowchart	January 2015
2.4C	1173 EFI_IFR_NUMERIC Errata	July 11, 2014
2.4C	1172 EfiACPIMemoryNVS definition missing S4	July 11, 2014
2.4C	1170 Errata pxeBc apiClarifiation	July 11, 2014
2.4C	1169 Errata - volatile networking variableCleanup	July 11, 2014
2.4C	1168 MTFTP Errata	July 11, 2014
2.4C	1165 Option rom layout errata	July 11, 2014
2.4C	1162 Typo in ReinstallProtocolInterface() EFI 1.10 Extension section	July 11, 2014
2.4C	1150 Missing LineBreakCharacter (HII Errata)	July 11, 2014
2.4C	1147 EFI_USB2_H C_PROTOCOL.AsyncInterruptTransfer() Errata	July 11, 2014
2.4C	1141 UEFI errata - ia32/x64 vector register management	July 11, 2014
2.4C	1140UEFI Errata - image execution info table	July 11, 2014
2.4C	1139 UEFI Errata on the storage securityCommand protocol	July 11, 2014
2.4C	1066 Errata–reference to missing table (90) removed	July 11, 2014
2.4C	1043 Ability to refresh the entire form [newContent]	July 11, 2014
2.4C	1042 AddBrowser Action Request "reconnect"	July 11, 2014
2.4B	1146 Typos andBroken links	April 17, 2014
2.4B	1137 Typographic errors in the 2.4 ErrataB draft	April 16, 2014
2.4B	1128 URI device path node redux–supersedes (defunct) 1119	April 4, 2014
2.4B	1127 USB Errata - unnecessary restriction on UEFI interrupt transfer types	March 27, 2014
2.4B	1124 Adding text description for NVMe device node	March 27, 2014
2.4B	1122Correct misleading language in the UEFI 2.4a specification about the EFI_ADAPTER_INFORMATION_PROTOCOL.EFI_ADAPTER_INFO_GET_SUPPORTED_TYPES function	March 27, 2014
2.4B	1120 Make time stamp handlingConsistent around all of the networking API's	March 27, 2014
2.4B	1118 Network Performance EnhancementsConcerning Volatile Variables	March 27, 2014

continues on next page

Table 2 – continued from previous page

2.4B	1115Clarification on the usage of XMM/FPU instructions from within a UEFI Runtime Service on an x64 processor	March 27, 2014
2.4B	1111 Errors in DisconnectController() returnCode descriptions	March 27, 2014
2.4B	1101 Errata – ReinstallProtocolInterface	March 27, 2014
2.4B	1092Clarification to PCI Option ROM Driver Loading Description	March 27, 2014
2.4B	1085 Error–added in missing text approved for 2.4A	April 17, 2014
2.4B	1014 HIIConfig Access Protocol Errata	April 3, 2014
2.4 A	1089 Short-termCPER Memory Section errata	Nov. 14, 2013
2.4 A	1088 Add revision #define to EFI_FILE_PROTOCOL	Nov. 6, 2013
2.4 A	1085 Issues with Interactive password	Nov.14, 2013
2.4 A	1082 Mistake in 2.3.5.1 / 2.3.6.2 Handoff State	Nov. 6, 2013
2.4 A	1081 Update Install Table protocol to deal with duplicate tables	Nov. 6, 2013
2.4 A	1079 UEFI 2.4: Remove repetitive “the” (typo)	Nov. 6, 2013
2.4 A	1078 Adjust some text for handling EFI_BROWSER_ACTION_CHANGING	Nov. 6, 2013
2.4 A	1077 Fix wording in EVT_SIGNAL_EXIT_BOOT_SERVICES	Nov. 6, 2013
2.4 A	1076 typo in UEFI v2.3.1d and v2.4	Nov. 6, 2013
2.4 A	1075Clarifications to Table 88. Device Node Table (Device Node to TextConversion)	Nov. 6, 2013
2.4 A	1074 AddClarifications on DMA requirements for PCI_IO	Nov. 6, 2013
2.4 A	1073 Add requirement for EFI_USB_IO_PROTOCOL	Nov. 6, 2013
2.4 A	1066 Errata - ISCSI IPV6 Root PathClarification	Nov. 6, 2013
2.4 A	1064 AIP Errata	Nov. 6, 2013
2.4 A	1063Correction to GPT expression for SizeofPartitionEntry	Nov. 6, 2013
2.4 A	1062 EFI_CERT_X509_GUID does not specify theCertificate encoding	Nov. 6, 2013
2.4 A	1061 UEFI 2.4 section 2.6.2 and 2.6.3 don’t use protocol hyperlinksConsistently	Nov. 6, 2013
2.4 A	1060 SlightClarification to FMP Authentication Requirments	Nov. 6, 2013
2.4 A	1059Clarification of a return statusCode of HASH protocol	Nov. 6, 2013
2.4 A	1058Correct mistake in the system table revision	Nov. 6, 2013
2.4 A	1056 text modification to definition of EF I_FIRMWARE_IMAGE_DESCRIPTOR_VERSION 2	Nov. 6, 2013
2.4 A	1055 Disk IO 2 errata	Nov. 6, 2013
2.4 A	1054 Deprecate 6 Hash Algorithms with inconsistent usage	Nov. 6, 2013
2.4 A	1053 Reduce Name space ofCapsule Result variable to increase performance	Nov. 6, 2013
2.4 A	1035 PCI Option ROM Errata (five figures)	Nov. 6, 2013
2.4	997 Driver Health Protocol errorCodes	April 25, 2013
2.4	993 (original ticket–supersededBy 1026)	
2.4	992 Adapter Information Protocol (AIP)	April 25, 2013
2.4	991 Greater than 256 NICs support on UNDI	April 25, 2013
2.4	968 HII Forms op-code for displaying a warning message	April 25, 2013
2.4	966 Spec typos	April 25, 2013
2.4	964 Disk IO 2 Protocol to support Async IO	April 25, 2013
2.4	963 Add new device path node NVM Express devices	April 25, 2013
2.4	956 Require network drivers to return EFI_NO_MEDIA	April 25, 2013
2.4	946 ForbidCreation of non-spec variables in EFI_GLOBAL_VARIABLE namespace	April 25, 2013
2.4	920 Add a variable for indicating out ofBand key modification	April 25, 2013

Table 2 – continued from previous page

2.3.1C	882 Indications Variable - OS/FW feature &CapabilityCommunication	June 13, 2012
2.3.1C	874 Provide a mechanism for providing keys in setup mode	June 13, 2012
2.3.1C	831 PXEBootCSA Type definitionCleanup	June 13, 2012
2.3.1B	896 StartImage andConnectController returnCodes	April 10, 2012
2.3.1B	893 SMMCommunication ACPI Table Update	April 10, 2012
2.3.1B	891Component Name Protocol References	April 10, 2012
2.3.1B	890 DriveConfiguration Protocol Phantom.	April 10, 2012
2.3.1B	888 typo in EFI_USB_HC Protocol	April 10, 2012
2.3.1B	887 union is declared twice in same section	April 10, 2012
2.3.1B	885 Errata in the GPT Table structureComment	April 10, 2012
2.3.1B	884 EFI_BOOT_KEY_DATA relies on implementation-definedBehavior	April 10, 2012
2.3.1B	881 netboot6 - multicast versus unicast	April 10, 2012
2.3.1B	880 netboot6Clarification/errata	April 10, 2012
2.3.1B	879 Reference to unsupported specification in SCSIChapter (14.1)	April 10, 2012
2.3.1B	878 Updated HII “Selected Form”Behaviors to Reflect NewCallback Results	April 10, 2012
2.3.1B	877 TableChecksum updateBy the ACPI_TABLE_PROTOCOL.InstallAcpiTable	April 10, 2012
2.3.1B	876 ToClarify EDID_OVERRIDE attribute definitions and expected operations	April 10, 2012
2.3.1B	873 Section 9.3.7 incorrectly assumes that all uses ofBBS device paths are non-UEFI	April 10, 2012
2.3.1B	872Change to SIMPLE_TEXT_INPUT_EX_PROTOCOL.RegisterKeyNotify/UnregisterKeyNotify	April 10, 2012
2.3.1B	871 Typo in InstallMultipleProtocolInterfaces	April 10, 2012
2.3.1B	870Clarify FrameBufferSize definition under EFI_GRAPHICS_OUTPUT_PROTOCOL_MODE struct	April 10, 2012
2.3.1B	869 Reference to FIPS 180 inChapter 27.3 is obsolete and incorrect	April 10, 2012
2.3.1B	867Clarify requirment for use of EFI_HASH_SERVICE_BINDING_PROTOCOL	April 10, 2012
2.3.1B	866 PK, KEK, db, dbx relationsClarification	April 10, 2012
2.3.1B	865 Modify Protective MBRBootIndicator definition	April 10, 2012
2.3.1B	864 Typo in Question-Level Validation section	April 10, 2012
2.3.1B	863 Attributes of the Globally Defined Variables	April 10, 2012
2.3.1B	862 User identity typo	April 10, 2012
2.3.1B	861 Globally Defined Variables Errata	April 10, 2012
2.3.1B	858 Superfluous and incorrect image hash description	April 10, 2012
2.3.1B	857 Absolute pointer typo	April 10, 2012
2.3.1B	855Clarification of UEFI driver signing/Code definitions	April 10, 2012
2.3.1B	853 The EFI_HASH_PROTOCOL.Hash() description needsClarification on padding responsibilities	April 10, 2012
2.3.1B	852 Various EFI_IFR_REFRESH_ID errata.	April 10, 2012
2.3.1B	851 For EFI_IFR_REFRESH opcode,Clarify RefreshInterval = 0 means no auto-refresh.	April 10, 2012
2.3.1B	850Clarification of responsibility for array allocation in EFI_HASH_PROTOCOL	April 10, 2012
2.3.1B	849 IFR EFI_IFR_MODAL_TAG_OP is also valid under EFI_IFR_FORM_MAP_OP	April 10, 2012

continues on next page

Table 2 – continued from previous page

2.3.1B	848Clarification of semantics of SecureBoot variable	April 10, 2012
2.3.1B	847 When enrolling a PK, the platform shall not require a reboot to leave SetupMode	April 10, 2012
2.3.1B	845 EFI_SCSI_PASS_THRU_PROTOCOL replacement	April 10, 2012
2.3.1B	842 Text to explain how the UEFI revision is referred	April 10, 2012
2.3.1B	836 StructureComment for EFI_IFR_TYPE_VALUE references unknown value type.	April 10, 2012
2.3.1B	828 Network Driver Options	April 10, 2012
2.3.1B	826Comments against Mantis 790	April 10, 2012
2.3.1B	825 DMTF SMCLP errata	April 10, 2012
2.3.1B	819 Mantis 715 was not fully implemented	April 10, 2012
2.3.1B	812 Errata – DUID-UUID usage	April 10, 2012
2.3.1B	809 Errata – Messaging Device PathClarification	April 10, 2012
2.3.1B	808 Errata –Boot File URL	April 10, 2012
2.3.1B	807 Give specific TPL rules to Stall()Boot services	April 10, 2012
2.3.1B	771 SHA1 and MD5 references	April 10, 2012
2.3.1A	MinorCorrections in toes to tickets 772, 785, 794, 804, also formattingCorrection for _WIN_CERTIFICATE_UEFI_GUID typedef's parameters	September 7, 2011
2.3.1A	820 Driver Health Needs to have Mantis 0000169 implemented	August 17, 2011
2.3.1A	819 ECR715 was not fully implemented	August 17, 2011
2.3.1A	806 Text update to Driver Health Description -Clarify role of user interaction	August 17, 2011
2.3.1A	805Correct Wrong Palette Information in 28.3.7.2.3 example	August 17, 2011
2.3.1A	804ClarifyContraints and alternatives when enrolling PK, KeK, db or dbx keys	August 17, 2011
2.3.1A	803 Fix AcpiExp device node text description.	August 17, 2011
2.3.1A	801ClarifyIFR Opcode Summary and Description #4	August 17, 2011
2.3.1A	800Clarify IFR Opcode Summary and Description #3	August 17, 2011
2.3.1A	797Clarify IFR Opcode Summary and Description #2	August 17, 2011
2.3.1A	796Clarify IFR Opcode Summary and Description #1	August 17, 2011
2.3.1A	795 Typo in ReadKeyStrokeEx()	August 17, 2011
2.3.1A	794 Incomplete text describingClearing of Platform Key	August 17, 2011
2.3.1A	793 Inconsistent wording about RemainingDevicePath	August 17, 2011
2.3.1A	790 Add warning to ReadKeyStrokeEx for partial key press	August 17, 2011
2.3.1A	789Clarify HII opcode definition	August 17, 2011
2.3.1A	788 SasEx entry in Table 86-Device Node TableContains optional Reserved entry that does not exist in device path	August 17, 2011
2.3.1A	786 PCI I/O Dual AddressCycle attributeClarification	August 17, 2011
2.3.1A	785 Allowing more general use of UEFI 2.3.1 Variable time-based authentication	August 17, 2011
2.3.1A	780 Errata in returnCode descriptions	August 17, 2011
2.3.1A	778 EFI_HI I_CONFIG_ACCESS_PROTOCOL.CallBack() Errata	August 17, 2011
2.3.1A	777 Specified signature sizes incorrect in Section 27.6.1	August 17, 2011
2.3.1A	776 Clarifycomputation of EFI_VARIABLE_ AUTHENTICATION_2 hash value	August 17, 2011
2.3.1A	774 Define EFI_BLOCK_IO_PROTOCOL_REVISION3	August 17, 2011
2.3.1A	773Clarify the value for opcode EFI_IFR_REFRESH_ID_OP	August 17, 2011
2.3.1A	772 Definition of EFI_IMAGE_SECURITY_DATABAE_GUID incorrect	August 17, 2011

Table 2 – continued from previous page

2.3.1A	770 Remove references to UEFI 2.1 spec	August 17, 2011
2.3.1A	767 The ReadBlocks function forBlockIO andBlockIO2 need synchronization	August 17, 2011
2.3.1A	212 (revisit) final sentence section 28.2.15 missing final words.	April 21, 2011
2.3.1	765 ECR to limit the hash and encryption algorithms used with PKCSCertificates	April 5, 2011
2.3.1	762 DevicePath in the Image Execution Information Table.	April 5, 2011
2.3.1	761 Table 195. Information for Types of Storage	April 5, 2011
2.3.1	760 SuggestedChanges to 2.3.1 final draft spec	April 5, 2011
2.3.1	759 UEFI Errata - wincerts for rest of hash algorithms	April 5, 2011
2.3.1	755 Errata in Legacy MBR table and Legacy MBR GUID	April 5, 2011
2.3.1	754 USB timeout parameter mismatch.	April 5, 2011
2.3.1	751 Fix USB HC2 erroneous references to IsSlowDevice	March 11, 2011
2.3.1	750 Fix section 27.2.5 “related definitions” re: RSA public key exponent	March 11, 2011
2.3.1	749 Fix Table 10 (Global Variables) WithCorrect Attributes	March 11, 2011
2.3.1	748Clarify Standard GUID Text Representation	March 11, 2011
2.3.1	744 ProcessorContext information structure definition notClear	March 11, 2011
2.3.1	741 Errata:Corrected text for section 7.2.1.4 step 7	March 11, 2011
2.3.1	740 Errata: signatureheadersize inconsistencyCorrections	April 6, 2011
2.3.1	736 Insert SMMCommunication ACPI Table and related data structures to the UEFI Specification	April 5, 2011
2.3.1	735Clarification on Tape Header Format	March 11, 2011
2.3.1	734 SecureBoot variable	April 5, 2011
2.3.1	733 Errata: 27.6.1 signatureheadersize definition	March 11, 2011
2.3.1	732 Amendment to Mantis 711: section 7.2.1.6	March 11, 2011
2.3.1	729 Errata:Clarification of Microsoft references in appendix Q	March 11, 2011
2.3.1	728 Netboot 6 errata - DUID-UUID	March 11, 2011
2.3.1	727 Errata on returnCode for User Info Identity policy record	March 11, 2011
2.3.1	726 Errata/clean-up of EFI_DHCP4_TRANSMIT_RECEIVE_TOKEN definition	March 11, 2011
2.3.1	724 SetVariable Update 2	March 11, 2011
2.3.1	723 User Identification (UID) Errata – EFI User Manager Notify & EnrollClarification	April 5, 2011
2.3.1	722 User Identification (UID) Errata –Credential Provider EnrollClarification	April 5, 2011
2.3.1	721 User Identification (UID) Errata – SetInfoClarification	March 11, 2011
2.3.1	720 User Identification (UID) Errata –Credential Provider EnrollClarification	March 11, 2011
2.3.1	716 EFI_EXT_SCSI_PASS_THRU_PROTOCOL.GetNextTarget() IN OUT parameter Target input value shallBe 0xFFs	March 11, 2011
2.3.1	715CPER Record and section fieldClarification	March 11, 2011
2.3.1	713 Remove the errata revision from the EFI_IFR_VERSION format.	March 11, 2011
2.3.1	711 SetVariable Update	March 11, 2011
2.3.1	709 NewCallback() Action Requests Related To Individual Forms.	Feb. 3, 2011
2.3.1	708 Errata (non-blockingBLOCK IO)	April 5, 2011
2.3.1	707 Errata revision in the EFI_IFR_VERSION format	Feb. 3, 2011
2.3.1	705 REPC signature definition stillConfusing	Feb. 3, 2011
2.3.1	704 Unload() definition is wrong	Feb. 3, 2011

Table 2 – continued from previous page

2.3	448 Section 28.2.5.4 Questions, Syntax, Update question-option-tag; Add EFI_IFR_READ and EFI_IFR_WRITE in the question syntax.	May 7, 2009
2.3	447Section 28.2.5.11.2 Moving Forms, Update line that starts with EFI_IFR_FORM to: EFI_IFR_FORM or EFI_IFR_FORM_MAP (and all references in EFI_IFR_REF)	May 7, 2009
2.3	446 Section 28.2.5.2 Forms, Syntax,Change 3rd line to: form := EFI_IFR_FORM form-tag-list | EFI_IFR_FORM_MAP form-tag-list	May 7, 2009
2.3	445 Table 194: EFI_IFR_FORM_MAP_OP, 2ndColumn shouldBe 0x5d (not 05xd)	May 7, 2009
2.3	444 Form Set Syntax: Section 28.2.5.1.1, section shouldBe sub-heading, not heading level 5; Section 28.2.5.1, Syntax, line 3, text after := is not aligned with other text on line 2, 4	May 7, 2009
2.3	443 Section 28.3.8.3.38, EFI_IFR_MAP, Prototype, line 4, outdent 2 spaces.	May 7, 2009
2.3	442 Section 28.3.8.3.64, EFI_IFR_SET, Prototype, lines 3-8, indentBy 2 spaces	May 7, 2009
2.3	440Change the defined type of EFI_STATUs from INTN to UINTN	May 7, 2009
2.3	439 Incorrect definitions of UEFI_CONFIG_LANG and UEFI_CONFIG_LANG_2 in UEFI 2.3 Feb18 draft	Feb 25, 2009
2.3	438 UEFI 2.3 Feb 13 Draft:Chapter 28 Formatting Issues	Feb 18, 2009
2.3	437 Errata to 2.3 draft material from UEFI Spec 2_3_Draft_Jan29	Feb 18, 2009
2.3	436 UEFI 2.3 split Figure 88 into 3 figures	Feb. 12, 2009
2.3	435 Partition SignatureClarification	Feb. 12, 2009
2.3	434 UEFI 2.3 Feb Draft: 28.3.8.3.58	Feb. 12, 2009
2.3	432 UEFI 2.3 Feb Draft: Appendix M.	Feb. 12, 2009
2.3	431 UEFI 2.3 Feb Draft: Section 30.4	Feb. 12, 2009
2.3	418Change Appendix O from “UEFI ACPI Table” to “UEFI ACPI Data	Feb 18, 2009
2.3	413Correct the definition of UEFI_CONFIG_LANG	Feb 18, 2009
2.3	410 UNDIBuffer usage	Feb 18, 2009
2.3	408 ARMBindingCorrections	Feb. 12, 2009
2.3	406 Missing EFI System Table Revision In UEFI 2.3 Draft	Feb. 12, 2009
2.3	395 New “Non-removable MediaBootBehavior” section	Feb. 12, 2009
2.3	394 Omission in EFI_USB2_HC_PROTOCOL	Feb. 12, 2009
2.3	388 Add HIICallback types (FORM_OPEN, FORM_CLOSE) when a form is opened orClosed.	Feb. 12, 2009
2.3	376 Add ARM processorBinding to UEFI	Jan. 12, 2009
2.3	326 Add Firmware Management Protocol	Feb. 12, 2009
2.2A	429 EFI_HASH_SERVICE_BINDING_PROTOCOL GUID define misses _GUID	Feb. 12, 2009
2.2A	404 RemoveConstraint form EFI_TIME.YearComment	Feb. 12, 2009
2.2A	400 FreePool() description error	Feb. 12, 2009
2.2A	393 UEFI 2.1/2.2Boot ManagerBehaviorClarification	Feb. 12, 2009
2.2A	392 MBR errata in UEFI 2.2	Feb. 12, 2009
2.2A	391 Polarity of INCONSISTENT_IF and NO_SUBMIT_IF IFR opcodes wrong	Feb. 12, 2009
2.2A	390 UEFI 2.2 Miscellaneous HII-related errata	Feb. 12, 2009
2.2A	389 UEFI 2.2 HII-Related Formatting Issues	Feb. 12, 2009

2.1A	UEFI 2.1 incorporating Errata through 4-27-07	April 27, 2007
2.1	Second release	January 23, 2007
2.0	First release of specification.	January 31, 2006

CHAPTER

ONE

INTRODUCTION

This *Unified Extensible Firmware Interface* (UEFI) *Specification* describes an interface between the operating system (OS) and the platform firmware. UEFI was preceded by the *Extensible Firmware Interface Specification 1.10* (EFI). As a result, some code and certain protocol names retain the EFI designation. Unless otherwise noted, EFI designations in this specification may be assumed to be part of UEFI.

The interface is in the form of data tables that contain platform-related information, and boot and runtime service calls that are available to the OS loader and the OS. Together, these provide a standard environment for booting an OS. This specification is designed as a pure interface specification. As such, the specification defines the set of interfaces and structures that platform firmware must implement. Similarly, the specification defines the set of interfaces and structures that the OS may use in booting. How either the firmware developer chooses to implement the required elements or the OS developer chooses to make use of those interfaces and structures is an implementation decision left for the developer.

The intent of this specification is to define a way for the OS and platform firmware to communicate only information necessary to support the OS boot process. This is accomplished through a formal and complete abstract specification of the software-visible interface presented to the OS by the platform and firmware.

Using this formal definition, a shrink-wrap OS intended to run on platforms compatible with supported processor specifications will be able to boot on a variety of system designs without further platform or OS customization. The definition will also allow for platform innovation to introduce new features and functionality that enhance platform capability without requiring new code to be written in the OS boot sequence.

Furthermore, an abstract specification opens a route to replace legacy devices and firmware code over time. New device types and associated code can provide equivalent functionality through the same defined abstract interface, again without impact on the OS boot support code.

The specification is applicable to a full range of hardware platforms from mobile systems to servers. The specification provides a core set of services along with a selection of protocol interfaces. The selection of protocol interfaces can evolve over time to be optimized for various platform market segments. At the same time, the specification allows maximum extensibility and customization abilities for OEMs to allow differentiation. In this, the purpose of UEFI is to define an evolutionary path from the traditional “PC-AT”-style boot world into a legacy-API free environment.

1.1 Principle of Inclusive Terminology

The UEFI Forum follows a Principle of Inclusive Terminology in building and maintaining content for specifications. This means that efforts are made to ensure that all wording is perceived or likely to be perceived as welcoming by everyone regardless of personal characteristics. In some cases, the Forum acknowledges that wording derived from earlier work, for example references to legacy specifications not controlled by the Forum, may not follow this principle. In order to preserve compatibility for code that reads on legacy specifications, particularly where that specification is no longer under maintenance or development, language in this specification may appear out of sync with the Principle. The Forum is resolved to work with other standards development bodies to eliminate such examples over time. In the meanwhile, by acknowledging and calling attention to this issue the hope is to promote discussion and action towards more complete use of Inclusive Language reflective of the diverse and innovative population of the technical community that works on standards.

1.2 UEFI Driver Model Extensions

Access to boot devices is provided through a set of protocol interfaces. One purpose of the UEFI *Driver Model* is to provide a replacement for "PC-AT"-style option ROMs. It is important to point out that drivers written to the UEFI *Driver Model* are designed to access boot devices in the preboot environment. They are not designed to replace the high-performance, OS-specific drivers.

The UEFI *Driver Model* is designed to support the execution of modular pieces of code, also known as drivers, that run in the preboot environment. These drivers may manage or control hardware buses and devices on the platform, or they may provide some software-derived, platform-specific service.

The UEFI *Driver Model* also contains information required by UEFI driver writers to design and implement any combination of bus drivers and device drivers that a platform might need to boot a UEFI-compliant OS.

The UEFI *Driver Model* is designed to be generic and can be adapted to any type of bus or device. The *UEFI Specification* describes how to write PCI bus drivers, PCI device drivers, USB bus drivers, USB device drivers, and SCSI drivers. Additional details are provided that allow UEFI drivers to be stored in PCI option ROMs, while maintaining compatibility with legacy option ROM images.

One of the design goals in the *UEFI Specification* is keeping the driver images as small as possible. However, if a driver is required to support multiple processor architectures, a driver object file would also be required to be shipped for each supported processor architecture. To address this space issue, this specification also defines the *EFI Byte Code Virtual Machine* . A UEFI driver can be compiled into a single EFI Byte Code object file. UEFI Specification-complaint firmware must contain an EFI Byte Code interpreter. This allows a single EFI Byte Code object file that supports multiple processor architectures to be shipped. Another space saving technique is the use of compression. This specification defines compression and decompression algorithms that may be used to reduce the size of UEFI Drivers, and thus reduce the overhead when UEFI Drivers are stored in ROM devices.

The information contained in the *UEFI Specification* can be used by OSVs, IHVs, OEMs, and firmware vendors to design and implement firmware conforming to this specification, drivers that produce standard protocol interfaces, and operating system loaders that can be used to boot UEFI-compliant operating systems.

1.3 Organization

The high-level organization of this specification is as follows:

Table 1.1: Organization of this specification

Section(s)	**Description**
Introduction / Overview	Introduces the UEFI Specification, and describes the major components of UEFI.
Boot Manager	Manager used to load drivers and applications written to this specification.
EFI System Table and Partitions	Describes an EFI System Table that is passed to every compliant driver and application, and defines a GUID-based partitioning scheme.
Block Transition Table	A layout and set of rules for doing block I/O that provide power fail write atomicity of a single block.
Boot Services	Contains the definitions of the fundamental services that are present in a UEFI-compliant system before an OS is booted.
Runtime Services	Contains definitions for the fundamental services that are present in a compliant system before and after an OS is booted.

Table 1.1 – continued from previous page

Protocols	• The EFI Loaded Image Protocol describes a UEFI Image that has been loaded into memory. • The Device Path Protocol provides the information needed to construct and manage device paths in the UEFI environment. • The UEFI Driver Model describes a set of services and protocols that apply to every bus and device type. • The Console Support Protocol defines I/O protocols that handle input and output of text-based information intended for the system user while executing in the boot services environment. • The Media Access Protocol defines the Load File protocol, file system format and media formats for handling removable media. • PCI Bus Support Protocols define PCI Bus Drivers, PCI Device Drivers, and PCI Option ROM layouts. The protocols described include the PCI Root Bridge I/O Protocol and the PCI I/O Protocol. • SCSI Driver Models and Bus support defines the SCSI I/O Protocol and the Extended SCSI Pass Thru Protocol that is used to abstract access to a SCSI channel that is produced by a SCSI host controller. • The iSCSI protocol defines a transport for SCSI data over TCP/IP. • The USB Support Protocol defines USB Bus Drivers and USB Device Drivers. • Debugger Support Protocols describe an optional set of protocols that provide the services required to implement a source-level debugger for the UEFI environment. • The Compression Algorithm Specification describes the compression/decompression algorithm in detail, plus a standard EFI decompression interface for use at boot time. • ACPI Protocols may be used to install or remove an ACPI table from a platform. • String Services: the Unicode Collation protocol allows code running in the boot services environment to perform lexical comparison functions on Unicode strings for given languages; the Regular Expression Protocol is used to match Unicode strings against Regular Expression patterns.
EFI Byte Code Virtual Machine	Defines the EFI Byte Code virtual processor and its instruction set. It also defines how EBC object files are loaded into memory, and the mechanism fo transitioning from native code to EBC code and back to native code.
Firmware Update and Reporting	Provides an abstraction for devices to provide firmware management support.

Table 1.1 – continued from previous page

Network Protocols	• SNP, PXE, BIS, and HTTP Boot protocols define the protocols that provide access to network devices while executing in the UEFI boot services environment. • Managed Network protocols define the EFI Managed Network Protocol, which provides raw (unformatted) asynchronous network packet I/O services and Managed Network Service Binding Protocol, used to locate communication devices that are supported by an MNP driver. • VLAN, EAP, Wi-Fi and Supplicant protocols define a protocol that is to provide a manageability interface for VLAN configurations. • Bluetooth protocol definitions. • TCP, IP, PIPsec, FTP, GTLS, and Configurations protocols define the EFI TCPv4 (Transmission Control Protocol version 4) Protocol and the EFI IPv4 (Internet Protocol version 4) Protocol. • ARP, DHCP, DNS, HTTP, and REST protocols define the EFI Address Resolution Protocol (ARP) Protocol interface and the EFI DHCPv4 Protocol. • UDP and MTFTP protocols define the EFI UDPv4 (User Datagram Protocol version 4) Protocol that interfaces over the EFI IPv4 Protocol and defines the EFI MTFTPv4 Protocol interface that is built on the EFI UDPv4 Protocol.
Secure Boot and Driver Signing	Describes Secure Boot and a means of generating a digital signature for UEFI.
Human Interface Infrastructure	• Defines the core code and (HII) services that are required for an implementation of the Human Interface Infrastructure (HII), including basic mechanisms for managing user input and code definitions for related protocols. • Describes the data and APIs used to manage the system's configuration: the actual data that describes the knobs and settings.
Section(s)	**Description**
User Identification	Describes services that describe the current user of the platform.
Secure Technologies	Describes the protocols for utilizing security technologies, including cryptographic hashing and key management.
Miscellaneous Protocols	The Timestamp protocol provides a platform independent interface for retrieving a high resolution timestamp counter. The Reset Notification Protocol provides services to register for a notification when ResetSystem is called.

Table 1.1 – continued from previous page

Appendices	• GUID and Time Formats. • Console requirements for a basic text-based console required by EFI-conformant systems to provide communication capabilities. • Device Path examples of use of the data structures that define various hardware devices to the boot services. • Status Codes lists success, error, and warning codes returned by UEFI interfaces. • Universal Network Driver Interfaces defines the 32/64-bit hardware and software Universal Network Driver Interfaces (UNDIs). • Using the Simple Pointer Protocol. • Using the EFI Extended SCISI Pass-thru Protocol. • Compression Source Code for an implementation of the Compression Algorithm. • Decompression Source Code for an implementation of the EFI Decompression Algorithm. • The EFI Byte Code Virtual Machine Opcode List provides a summary of the corresponding instruction set. • Alphabetic Function Lists identify all UEFI interface functions alphabetically. • EFI 1.10 Protocol Changes and Depreciation List identifies the Protocol, GUID, and revision identifier name changes and the deprecated protocols compared to the EFI Specification 1.10. • Formats: Language Codes and Language Code Arrays list the formats for language codes and language code arrays. • The Common Platform Error Record describes the common platform error record format for representing platform hardware errors. • The UEFI ACPI Data Table defines the UEFI ACPI table format. • Hardware Error Record Persistence Usage. • References • Glossary
Index	Provides an index to the key terms and concepts in the specification.

1.4 Goals

The "PC-AT" boot environment presents significant challenges to innovation within the industry. Each new platform capability or hardware innovation requires firmware developers to craft increasingly complex solutions, and often requires OS developers to make changes to their boot code before customers can benefit from the innovation. This can be a time-consuming process requiring a significant investment of resources.

The primary goal of the UEFI specification is to define an alternative boot environment that can alleviate some of these considerations. In this goal, the specification is similar to other existing boot specifications. The main properties of this specification can be summarized by these attributes:

- *Coherent, scalable platform environment*. The specification defines a complete solution for the firmware to describe all platform features and surface platform capabilities to the OS during the boot process. The definitions are rich enough to cover a range of contemporary processor designs.
- *Abstraction of the OS from the firmware*. The specification defines interfaces to platform capabilities. Through the use of abstract interfaces, the specification allows the OS loader to be constructed with far less knowledge of the platform and firmware that underlie those interfaces. The interfaces represent a well-defined and stable boundary between the underlying platform and firmware implementation and the OS loader. Such a bound-

ary allows the underlying firmware and the OS loader to change provided both limit their interactions to the defined interfaces. The standard interfaces defined in this specification may be complemented by companion OS/firmware interfaces such as those defined by the ACPI specification. On the other hand, firmware-internal interfaces, such as those defined by the PI Specification, are produced and consumed by firmware only, and are not considered interfaces that a UEFI aware OS can connect to, interact with, or depend on.

- *Reasonable device abstraction free of legacy interfaces*. "PC-AT" BIOS interfaces require the OS loader to have specific knowledge of the workings of certain hardware devices. This specification provides OS loader developers with something different: abstract interfaces that make it possible to build code that works on a range of underlying hardware devices without having explicit knowledge of the specifics for each device in the range.
- *Abstraction of Option ROMs from the firmware*. This specification defines interfaces to platform capabilities including standard bus types such as PCI, USB, and SCSI. The list of supported bus types may grow over time, so a mechanism to extend to future bus types is included. These defined interfaces, and the ability to extend to future bus types, are components of the UEFI *Driver Model*. One purpose of the UEFI *Driver Model* is to solve a wide range of issues that are present in existing "PC-AT" option ROMs. Like OS loaders, drivers use the abstract interfaces so device drivers and bus drivers can be constructed with far less knowledge of the platform and firmware that underlie those interfaces.
- *Architecturally shareable system partition*. Initiatives to expand platform capabilities and add new devices often require software support. In many cases, when these platform innovations are activated before the OS takes control of the platform, they must be supported by code that is specific to the platform rather than to the customer's choice of OS. The traditional approach to this problem has been to embed code in the platform during manufacturing (for example, in flash memory devices). Demand for such persistent storage is increasing at a rapid rate. This specification defines persistent store on large mass storage media types for use by platform support code extensions to supplement the traditional approach. The definition of how this works is made clear in the specification to ensure that firmware developers, OEMs, operating system vendors, and perhaps even third parties can share the space safely while adding to platform capability.

Defining a boot environment that delivers these attributes could be accomplished in many ways. Indeed, several alternatives, perhaps viable from an academic point of view, already existed at the time this specification was written. These alternatives, however, typically presented high barriers to entry given the current infrastructure capabilities surrounding supported processor platforms. This specification is intended to deliver the attributes listed above, while also recognizing the unique needs of an industry that has considerable investment in compatibility and a large installed base of systems that cannot be abandoned summarily. These needs drive the requirements for the additional attributes embodied in this specification:

- *Evolutionary, not revolutionary*. The interfaces and structures in the specification are designed to reduce the burden of an initial implementation as much as possible. While care has been taken to ensure that appropriate abstractions are maintained in the interfaces themselves, the design also ensures that reuse of BIOS code to implement the interfaces is possible with a minimum of additional coding effort. In other words, on PC-AT platforms the specification can be implemented initially as a thin interface layer over an underlying implementation based on existing code. At the same time, introduction of the abstract interfaces provides for migration away from legacy code in the future. Once the abstraction is established as the means for the firmware and OS loader to interact during boot, developers are free to replace legacy code underneath the abstract interfaces at leisure. A similar migration for hardware legacy is also possible. Since the abstractions hide the specifics of devices, it is possible to remove underlying hardware, and replace it with new hardware that provides improved functionality, reduced cost, or both. Clearly this requires that new platform firmware be written to support the device and present it to the OS loader via the abstract interfaces. However, without the interface abstraction, removal of the legacy device might not be possible at all.
- *Compatibility by design*. The design of the system partition structures also preserves all the structures that are currently used in the "PC-AT" boot environment. Thus, it is a simple matter to construct a single system that is capable of booting a legacy OS or an EFI-aware OS from the same disk.
- *Simplifies addition of OS-neutral platform value-add*. The specification defines an open, extensible interface that lends itself to the creation of platform "drivers." These may be analogous to OS drivers, providing support for

new device types during the boot process, or they may be used to implement enhanced platform capabilities, such as fault tolerance or security. Furthermore, this ability to extend platform capability is designed into the specification from the outset. This is intended to help developers avoid many of the frustrations inherent in trying to squeeze new code into the traditional BIOS environment. As a result of the inclusion of interfaces to add new protocols, OEMs or firmware developers have an infrastructure to add capability to the platform in a modular way. Such drivers may potentially be implemented using high-level coding languages because of the calling conventions and environment defined in the specification. This in turn may help to reduce the difficulty and cost of innovation. The option of a system partition provides an alternative to nonvolatile memory storage for such extensions.

- *Built on existing investment*. Where possible, the specification avoids redefining interfaces and structures in areas where existing industry specifications provide adequate coverage. For example, the ACPI specification provides the OS with all the information necessary to discover and configure platform resources. Again, this philosophical choice for the design of the specification is intended to keep barriers to its adoption as low as possible.

1.5 Target Audience

This document is intended for the following readers:

- IHVs and OEMs who will be implementing UEFI drivers.
- OEMs who will be creating supported processor platforms intended to boot shrink-wrap operating systems.
- BIOS developers, either those who create general-purpose BIOS and other firmware products or those who modify these products for use in supported processor-based products.
- Operating system developers who will be adapting their shrink-wrap operating system products to run on supported processor-based platforms.

1.6 UEFI Design Overview

The design of UEFI is based on the following fundamental elements:

- *Reuse of existing table-based interfaces*. In order to preserve investment in existing infrastructure support code, both in the OS and firmware, a number of existing specifications that are commonly implemented on platforms compatible with supported processor specifications must be implemented on platforms wishing to comply with the UEFI specification. (For additional information, see *Appendix Q — References*.)
- *System partition*. The System partition defines a partition and file system that are designed to allow safe sharing between multiple vendors, and for different purposes. The ability to include a separate, sharable system partition presents an opportunity to increase platform value-add without significantly growing the need for nonvolatile platform memory.
- *Boot services*. Boot services provide interfaces for devices and system functionality that can be used during boot time. Device access is abstracted through "handles" and "protocols." This facilitates reuse of investment in existing BIOS code by keeping underlying implementation requirements out of the specification without burdening the consumer accessing the device.
- *Runtime services*. A minimal set of runtime services is presented to ensure appropriate abstraction of base platform hardware resources that may be needed by the OS during its normal operations.

The Figure below shows the principal components of UEFI and their relationship to platform hardware and OS software.

This Figure illustrates the interactions of the various components of an UEFI specification-compliant system that are used to accomplish platform and OS boot.

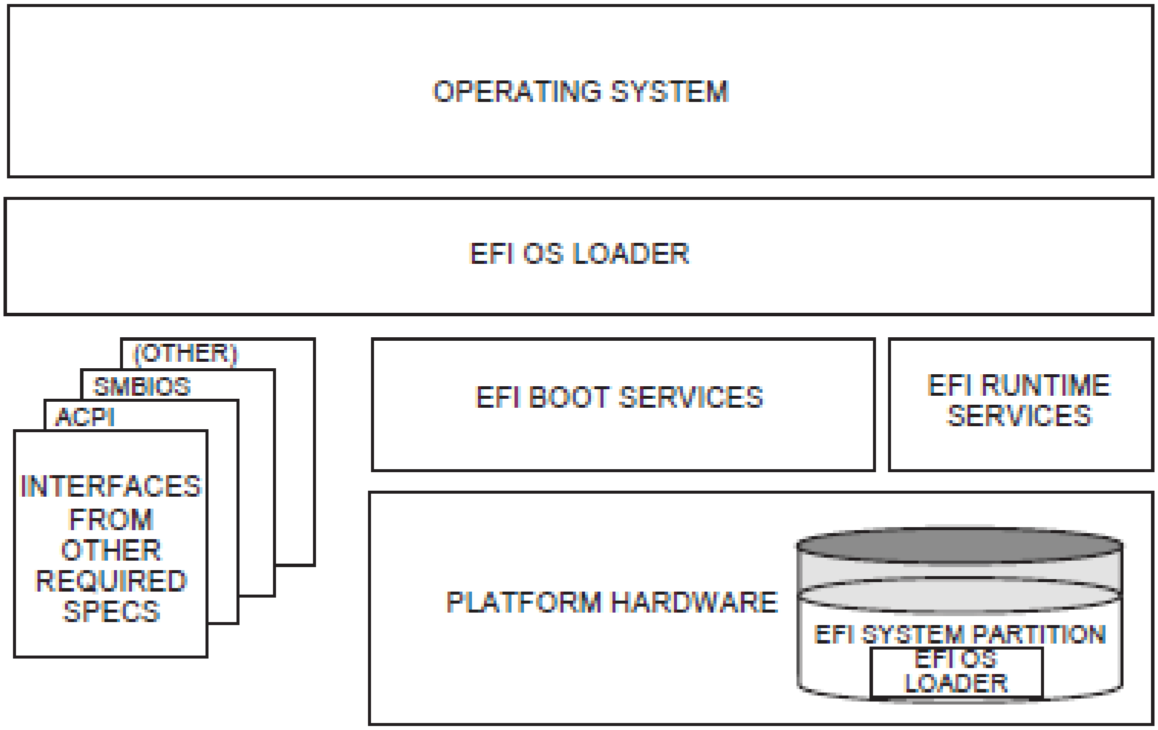

Fig. 1.1: UEFI Conceptual Overview

The platform firmware is able to retrieve the OS loader image from the System Partition. The specification provides for a variety of mass storage device types including disk, CD-ROM, and DVD as well as remote boot via a network. Through the extensible protocol interfaces, it is possible to add other boot media types, although these may require OS loader modifications if they require use of protocols other than those defined in this document.

Once started, the OS loader continues to boot the complete operating system. To do so, it may use the EFI boot services and interfaces defined by this or other required specifications to survey, comprehend, and initialize the various platform components and the OS software that manages them. EFI runtime services are also available to the OS loader during the boot phase.

1.7 UEFI Driver Model

This section describes the goals of a driver model for firmware conforming to this specification. The goal is for this driver model to provide a mechanism for implementing bus drivers and device drivers for all types of buses and devices. At the time of writing, supported bus types include PCI, USB, and so on.

As hardware architectures continue to evolve, the number and types of buses present in platforms are increasing. This trend is especially true in high-end servers. However, a more diverse set of bus types is being designed into desktop and mobile systems and even some embedded systems. This increasing complexity means that a simple method for describing and managing all the buses and devices in a platform is required in the preboot environment. The UEFI *Driver Model* provides this simple method in the form of protocols services and boot services.

1.7.1 UEFI Driver Model Goals

The UEFI *Driver Model* has the following goals:

- *Compatible* — Drivers conforming to this specification must maintain compatibility with the *EFI 1.10 Specification* and the *UEFI Specification* . This means that the UEFI *Driver Model* takes advantage of the extensibility mechanisms in the *UEFI 2. 0 Specification* to add the required functionality.
- *Simple* — Drivers that conform to this specification must be simple to implement and simple to maintain. The UEFI *Driver Model* must allow a driver writer to concentrate on the specific device for which the driver is being developed. A driver should not be concerned with platform policy or platform management issues. These considerations should be left to the system firmware.
- *Scalable* — The UEFI *Driver Model* must be able to adapt to all types of platforms. These platforms include embedded systems, mobile, and desktop systems, as well as workstations and servers.
- *Flexible* — The UEFI *Driver Model* must support the ability to enumerate all the devices, or to enumerate only those devices required to boot the required OS. The minimum device enumeration provides support for more rapid boot capability, and the full device enumeration provides the ability to perform OS installations, system maintenance, or system diagnostics on any boot device present in the system.
- *Extensible* — The UEFI *Driver Model* must be able to extend to future bus types as they are defined.
- *Portable* — Drivers written to the UEFI *Driver Model* processor architectures.
- *Interoperable* — Drivers must coexist with other drivers and system firmware and must do so without generating resource conflicts.
- *Describe complex bus hierarchies* — The UEFI *Driver Model* must be able to describe a variety of bus topologies from very simple single bus platforms to very complex platforms containing many buses of various types.
- *Small driver footprint* — The size of executables produced by the UEFI *Driver Model* must be minimized to reduce the overall platform cost. While flexibility and extensibility are goals, the additional overhead required to support these must be kept to a minimum to prevent the size of firmware components from becoming unmanageable.
- *Address legacy option rom issues* — The UEFI *Driver Model* must directly address and solve the constraints and limitations of legacy option ROMs. Specifically, it must be possible to build add-in cards that support both UEFI drivers and legacy option ROMs, where such cards can execute in both legacy BIOS systems and UEFI-conforming platforms, without modifications to the code carried on the card. The solution must provide an evolutionary path to migrate from legacy option ROMs driver to UEFI drivers.

1.7.2 Legacy Option ROM Issues

This idea of supporting a driver model came from feedback on the *UEFI Specification* that provided a clear, market-driven requirement for an alternative to the legacy option ROM (sometimes also referred to as an expansion ROM). The perception is that the advent of the *UEFI Specification* represents a chance to escape the limitations implicit in the construction and operation of legacy option ROM images by replacing them with an alternative mechanism that works within the framework of the *UEFI Specification* .

1.8 Migration Requirements

Migration requirements cover the transition period from initial implementation of this specification to a future time when all platforms and operating systems implement to this specification. During this period, two major compatibility considerations are important:

- The ability to continue booting legacy operating systems;
- The ability to implement UEFI on existing platforms by reusing as much existing firmware code to keep development resource and time requirements to a minimum.

1.8.1 Legacy Operating System Support

The UEFI specification represents the preferred means for a shrink-wrap OS and firmware to communicate during the boot process. However, choosing to make a platform that complies with this specification in no way precludes a platform from also supporting existing legacy OS binaries that have no knowledge of the UEFI specification.

The UEFI specification does not restrict a platform designer who chooses to support both the UEFI specification and a more traditional "PC-AT" boot infrastructure. If such a legacy infrastructure is to be implemented, it should be developed in accordance with existing industry practice that is defined outside the scope of this specification. The choice of legacy operating systems that are supported on any given platform is left to the manufacturer of that platform.

1.8.2 Supporting the UEFI Specification on a Legacy Platform

The UEFI specification has been carefully designed to allow for existing systems to be extended to support it with a minimum of development effort. In particular, the abstract structures and services defined in the UEFI specification can all be supported on legacy platforms.

For example, to accomplish such support on an existing and supported 32-bit-based platform that uses traditional BIOS to support operating system boot, an additional layer of firmware code would need to be provided. This extra code would be required to translate existing interfaces for services and devices into support for the abstractions defined in this specification.

1.9 Conventions Used in this Document

This document uses typographic and illustrative conventions described below.

1.9.1 Data Structure Descriptions

Supported processors are "little endian" machines. This distinction means that the low-order byte of a multibyte data item in memory is at the lowest address, while the high-order byte is at the highest address. Some supported 64-bit processors may be configured for both "little endian" and "big endian" operation. All implementations designed to conform to this specification use "little endian" operation.

In some memory layout descriptions, certain fields are marked *reserved* . Software must initialize such fields to zero and ignore them when read. On an update operation, software must preserve any reserved field.

1.9.2 Protocol Descriptions

A protocol description generally has the following format:

Protocol Name: The formal name of the protocol interface.

Summary: A brief description of the protocol interface.

GUID: The 128-bit Globally Unique Identifier (GUID) for the protocol interface.

Protocol Interface Structure: A "C-style" data structure definition containing the procedures and data fields produced by this protocol interface.

Parameters: A brief description of each field in the protocol interface structure.

Description: A description of the functionality provided by the interface, including any limitations and caveats of which the caller should be aware.

Related Definitions: The type declarations and constants that are used in the protocol interface structure or any of its procedures.

1.9.3 Procedure Descriptions

A procedure description generally has the following format:

ProcedureName(): The formal name of the procedure.

Summary: A brief description of the procedure.

Prototype: A "C-style" procedure header defining the calling sequence.

Parameters: A brief description of each field in the procedure prototype.

Description: A description of the functionality provided by the interface, including any limitations and caveats of which the caller should be aware.

Related Definitions: The type declarations and constants that are used only by this procedure.

Status Codes Returned: A description of any codes returned by the interface. The procedure is required to implement any status codes listed in this table. Additional error codes may be returned, but they will not be tested by standard compliance tests, and any software that uses the procedure cannot depend on any of the extended error codes that an implementation may provide.

1.9.4 Instruction Descriptions

An instruction description for EBC instructions generally has the following format:

InstructionName: The formal name of the instruction.

Syntax: A brief description of the instruction.

Description: A description of the functionality provided by the instruction accompanied by a table that details the instruction encoding.

Operation: Details the operations performed on operands.

Behaviors and Restrictions: An item-by-item description of the behavior of each operand involved in the instruction and any restrictions that apply to the operands or the instruction.

1.9.5 Pseudo-Code Conventions

Pseudo code is presented to describe algorithms in a more concise form. None of the algorithms in this document are intended to be compiled directly. The code is presented at a level corresponding to the surrounding text.

In describing variables, a *list* is an unordered collection of homogeneous objects. A *queue* is an ordered list of homogeneous objects. Unless otherwise noted, the ordering is assumed to be FIFO.

Pseudo code is presented in a C-like format, using C conventions where appropriate. The coding style, particularly the indentation style, is used for readability and does not necessarily comply with an implementation of the *UEFI Specification* .

1.9.6 Typographic Conventions

This document uses the typographic and illustrative conventions described below:

Plain text

> The normal text typeface is used for the vast majority of the descriptive text in a specification.

Plain text (blue)

> Any plain text that is underlined and in blue indicates an active link to the cross-reference. Click on the word to follow the hyperlink.

Bold

> In text, a **Bold** typeface identifies a processor register name. In other instances, a **Bold** typeface can be used as a running head within a paragraph.

Italic

> In text, an *Italic* typeface can be used as emphasis to introduce a new term or to indicate a manual or specification name.

BOLD Monospace

> Computer code, example code segments, and all prototype code segments use a **BOLD Monospace** typeface with a dark red color. These code listings normally appear in one or more separate paragraphs, though words or segments can also be embedded in a normal text paragraph.

Bold Monospace (Blue, underlined)

> Words in a Bold Monospace typeface that is underlined and in blue indicate an active hyperlink to the code definition for that function or type definition. Click on the word to follow the hyperlink.

Note: *Due to management and file size considerations, only the first occurrence of the reference on each page is an active link. Subsequent references on the same page will not be actively linked to the definition and will use the standard, nonunderlined* BOLD Monospace *typeface. Find the first instance of the name (in the underlined* BOLD Monospace *typeface) on the page and click on the word to jump to the function or type definition.*

Italic Monospace

> In code or in text, words in *Italic Monospace* indicate placeholder names for variable information that must be supplied (i.e., arguments).

1.9.7 Number formats

A binary number is represented in this standard by any sequence of digits consisting of only the Western-Arabic numerals 0 and 1 immediately followed by a lower-case b (e.g., 0101b).

Underscores or spaces may be included between characters in binary number representations to increase readability or delineate field boundaries (e.g., 0 0101 1010b or 0_0101_1010b).

1.9.7.1 Hexadecimal

A hexadecimal number is represented in this standard by 0x preceding any sequence of digits consisting of only the Western-Arabic numerals 0 through 9 and/or the upper-case English letters A through F (e.g., 0xFA23).

Underscores or spaces may be included between characters in hexadecimal number representations to increase readability or delineate field boundaries (e.g., 0xB FD8C FA23 or 0xB_FD8C_FA23).

1.9.7.2 Decimal

A decimal number is represented in this standard by any sequence of digits consisting of only the Arabic numerals 0 through 9 not immediately followed by a lower-case b or lower-case h (e.g., 25).

This standard uses the following conventions for representing decimal numbers:

- the decimal separator (i.e., separating the integer and fractional portions of the number) is a period;
- the thousands separator (i.e., separating groups of three digits in a portion of the number) is a comma;
- the thousands separator is used in the integer portion and is not used in the fraction portion of a number.

1.9.8 SI & Binary prefixes

This standard uses the prefixes defined in the International System of Units (SI) for values that are powers of ten. See "Links to UEFI-Related Documents" (http://uefi.org/uefi) under the heading "SI Binary Prefixes".

SI prefixes

Table 1.2: SI Prefixes

10^3	1,000	kilo	K
10^6	1,000,000	mega	M
10^9	1,000,000,000	giga	G

This standard uses the binary prefixes defined in ISO/IEC 80000-13 Quantities and units – Part 13: Information science and technology and IEEE 1514 Standard for Prefixes for Binary Multiples for values that are powers of two.

Binary prefixes

Table 1.3: Binary Prefixes

Factor	Factor	Name	Symbol
2^{10}	1,024	kibi	Ki
2^{20}	1,048,576	mebi	Mi
2^{30}	1,073,741,824	gibi	Gi

For example, 4 KB means 4,000 bytes and 4 KiB means 4,096 bytes.

1.9.9 Revision Numbers

Updates to the UEFI specification are considered either new revisions or errata as described below:

- A new revision is produced when there is substantive new content or changes that may modify existing behavior. New revisions are designated by a major.minor version number (e.g. xx.yy). In cases where the changes are exceptionally minor, we may have a major.minor.minor naming convention (e.g. xx.yy.zz).
- Errata versions are produced when approved updates to the specification do not include any significant new material or modify existing behavior. Errata are designated by adding an upper-case letter at the end of the version number, such as xx.yy errata A.

CHAPTER

TWO

OVERVIEW

UEFI allows the extension of platform firmware by loading UEFI driver and UEFI application images. When UEFI drivers and UEFI applications are loaded they have access to all UEFI-defined runtime and boot services. See the Booting Sequence figure below.

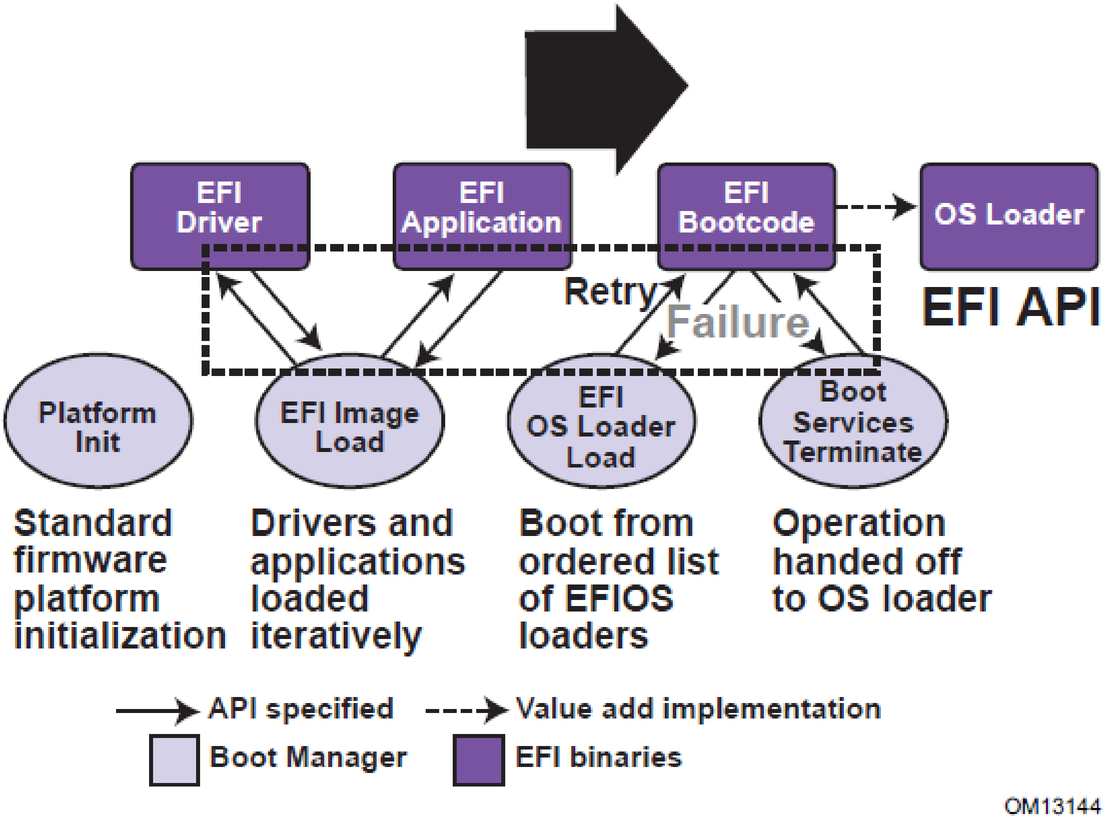

Fig. 2.1: **Booting Sequence**

UEFI allows the consolidation of boot menus from the OS loader and platform firmware into a single platform firmware menu. These platform firmware menus will allow the selection of any UEFI OS loader from any partition on any boot medium that is supported by UEFI boot services. An UEFI OS loader can support multiple options that can appear on the user interface. It is also possible to include legacy boot options, such as booting from the A: or C: drive in the platform firmware boot menus.

UEFI supports booting from media that contain an UEFI OS loader or an UEFI-defined System Partition. An UEFI-defined System Partition is required by UEFI to boot from a block device. UEFI does not require any change to the first sector of a partition, so it is possible to build media that will boot on both legacy architectures and UEFI platforms.

2.1 Boot Manager

UEFI contains a boot manager that allows the loading of applications written to this specification (including OS first stage loader) or UEFI drivers from any file on an UEFI-defined file system or through the use of an UEFI-defined image loading service. UEFI defines NVRAM variables that are used to point to the file to be loaded. These variables also contain application-specific data that are passed directly to the UEFI application. The variables also contain a human readable string that can be displayed in a menu to the user.

The variables defined by UEFI allow the system firmware to contain a boot menu that can point to all of the operating systems, and even multiple versions of the same operating systems. The design goal of UEFI was to have one set of boot menus that could live in platform firmware. UEFI specifies only the NVRAM variables used in selecting boot options. UEFI leaves the implementation of the menu system as value added implementation space.

UEFI greatly extends the boot flexibility of a system over the current state of the art in the PC-AT-class system. The PC-AT-class systems today are restricted to boot from the first floppy, hard drive, CD-ROM, USB keys, or network card attached to the system. Booting from a common hard drive can cause many interoperability problems between operating systems, and different versions of operating systems from the same vendor.

2.1.1 UEFI Images

UEFI Images are a class of files defined by UEFI that contain executable code. The most distinguishing feature of UEFI Images is that the first set of bytes in the UEFI Image file contains an image header that defines the encoding of the executable image.

UEFI uses a subset of the PE32+ image format with a modified header signature. The modification to the signature value in the PE32+ image is done to distinguish UEFI images from normal PE32 executables. The "+" addition to PE32 provides the 64-bit relocation fix-up extensions to standard PE32 format.

For images with the UEFI image signature, the Subsystem values in the PE image header are defined below. The major differences between image types are the memory type that the firmware will load the image into, and the action taken when the image's entry point exits or returns. A UEFI application image is always unloaded when control is returned from the image's entry point. A UEFI driver image is only unloaded if control is passed back with a UEFI error code.

```
// PE32+ Subsystem type for EFI images
#define EFI_IMAGE_SUBSYSTEM_EFI_APPLICATION         10
#define EFI_IMAGE_SUBSYSTEM_EFI_BOOT_SERVICE_DRIVER 11
#define EFI_IMAGE_SUBSYSTEM_EFI_RUNTIME_DRIVER      12

// PE32+ Machine type for EFI images
#define EFI_IMAGE_MACHINE_IA32                      0x014c
#define EFI_IMAGE_MACHINE_IA64                      0x0200
#define EFI_IMAGE_MACHINE_EBC                       0x0EBC
#define EFI_IMAGE_MACHINE_x64                       0x8664
#define EFI_IMAGE_MACHINE_ARMTHUMB_MIXED            0x01C2
#define EFI_IMAGE_MACHINE_AARCH64                   0xAA64
#define EFI_IMAGE_MACHINE_RISCV32                   0x5032
#define EFI_IMAGE_MACHINE_RISCV64                   0x5064
#define EFI_IMAGE_MACHINE_RISCV128                  0x5128
```

Note: This image type is chosen to enable UEFI images to contain Thumb and Thumb2 instructions while defining the EFI interfaces themselves to be in ARM mode.

Table 2.1: UEFI Image Memory Types

Subsystem Type	Code Memory Type	Data Memory Type
EFI_IMAGE_SUSBSYTEM_EFI_APPLICATION	EfiLoaderCode	EfiLoaderData
EFI_IMAGE_SUBSYSTEM_EFI_BOOT_SERVICE_DRIVER	EfiBootServicesCode	EfiBootServicesData
EFI_IMAGE_SUBSYSTEM_EFI_RUNTIME_DRIVER	EfiRuntimeServicesCode	EfiRuntimeServicesData

The Machine value that is found in the PE image file header is used to indicate the machine code type of the image. The machine code types for images with the UEFI image signature are defined below. A given platform must implement the image type native to that platform and the image type for EFI Byte Code (EBC). Support for other machine code types is optional to the platform.

A UEFI image is loaded into memory through the *EFI_BOOT_SERVICES.LoadImage()* Boot Service. This service loads an image with a PE32+ format into memory. This PE32+ loader is required to load all sections of the PE32+ image into memory. Once the image is loaded into memory, and the appropriate fix-ups have been performed, control is transferred to a loaded image at the AddressOfEntryPoint reference according to the normal indirect calling conventions of applications based on supported 32-bit, 64-bit, or 128-bit processors. All other linkage to and from an UEFI image is done programmatically.

2.1.2 UEFI Applications

Applications written to this specification are loaded by the Boot Manager or by other UEFI applications. To load a UEFI application the firmware allocates enough memory to hold the image, copies the sections within the UEFI application image to the allocated memory, and applies the relocation fix-ups needed. Once done, the allocated memory is set to be the proper type for code and data for the image. Control is then transferred to the UEFI application's entry point. When the application returns from its entry point, or when it calls the Boot Service *EFI_BOOT_SERVICES.LoadImage()*, the UEFI application is unloaded from memory and control is returned to the UEFI component that loaded the UEFI application.

When the Boot Manager loads a UEFI application, the image handle may be used to locate the "load options" for the UEFI application. The load options are stored in nonvolatile storage and are associated with the UEFI application being loaded and executed by the Boot Manager.

2.1.3 UEFI OS Loaders

A UEFI OS loader is a special type of UEFI application that normally takes over control of the system from firmware conforming to this specification. When loaded, the UEFI OS loader behaves like any other UEFI application in that it must only use memory it has allocated from the firmware and can only use UEFI services and protocols to access the devices that the firmware exposes. If the UEFI OS loader includes any boot service style driver functions, it must use the proper UEFI interfaces to obtain access to the bus specific-resources. That is, I/O and memory-mapped device registers must be accessed through the proper bus specific I/O calls like those that a UEFI driver would perform.

If the UEFI OS loader experiences a problem and cannot load its operating system correctly, it can release all allocated resources and return control back to the firmware via the Boot Service Exit() call. The Exit() call allows both an error code and ExitData to be returned. The ExitData contains both a string and OS loader-specific data to be returned. If the UEFI OS loader successfully loads its operating system, it can take control of the system by using the Boot

Service *EFI_BOOT_SERVICES.ExitBootServices()* . After successfully calling ExitBootServices() , all boot services in the system are terminated, including memory management, and the UEFI OS loader is responsible for the continued operation of the system.

2.1.4 UEFI Drivers

UEFI drivers are loaded by the Boot Manager, firmware conforming to this specification, or by other UEFI applications. To load a UEFI driver the firmware allocates enough memory to hold the image, copies the sections within the UEFI driver image to the allocated memory and applies the relocation fix-ups needed. Once done, the allocated memory is set to be the proper type for code and data for the image. Control is then transferred to the UEFI driver's entry point. When the UEFI driver returns from its entry point, or when it calls the Boot Service *EFI_BOOT_SERVICES.ExitBootServices()* , the UEFI driver is optionally unloaded from memory and control is returned to the component that loaded the UEFI driver. A UEFI driver is not unloaded from memory if it returns a status code of EFI_SUCCESS . If the UEFI driver's return code is an error status code, then the driver is unloaded from memory.

There are two types of UEFI drivers: boot service drivers and runtime drivers. The only difference between these two driver types is that UEFI runtime drivers are available after a UEFI OS loader has taken control of the platform with the Boot Service *EFI_BOOT_SERVICES.ExitBootServices()*.

UEFI boot service drivers are terminated when ExitBootServices() is called, and all the memory resources consumed by the UEFI boot service drivers are released for use in the operating system environment.

A runtime driver of type EFI_IMAGE_SUBSYSTEM_EFI_RUNTIME_DRIVER gets fixed up with virtual mappngs when the OS calls *SetVirtualAddressMap()* .

2.2 Firmware Core

This section provides an overview of the services defined by UEFI. These include boot services and runtime services.

2.2.1 UEFI Services

The purpose of the UEFI interfaces is to define a common boot environment abstraction for use by loaded UEFI images, which include UEFI drivers, UEFI applications, and UEFI OS loaders. The calls are defined with a full 64-bit interface, so that there is headroom for future growth. The goal of this set of abstracted platform calls is to allow the platform and OS to evolve and innovate independently of one another. Also, a standard set of primitive runtime services may be used by operating systems.

Platform interfaces defined in this section allow the use of standard Plug and Play Option ROMs as the underlying implementation methodology for the boot services. The interfaces have been designed in such as way as to map back into legacy interfaces. These interfaces have in no way been burdened with any restrictions inherent to legacy Option ROMs.

The UEFI platform interfaces are intended to provide an abstraction between the platform and the OS that is to boot on the platform. The UEFI specification also provides abstraction between diagnostics or utility programs and the platform; however, it does not attempt to implement a full diagnostic OS environment. It is envisioned that a small diagnostic OS-like environment can be easily built on top of an UEFI system. Such a diagnostic environment is not described by this specification. Interfaces added by this specification are divided into the following categories and are detailed later in this document:

- Runtime services
- Boot services interfaces, with the following subcategories:
  - Global boot service interfaces

- – Device handle-based boot service interfaces
- – Device protocols
- – Protocol services

2.2.2 Runtime Services

This section describes UEFI runtime service functions. The primary purpose of the runtime services is to abstract minor parts of the hardware implementation of the platform from the OS. Runtime service functions are available during the boot process and also at runtime provided the OS switches into flat physical addressing mode to make the runtime call. However, if the OS loader or OS uses the Runtime Service *SetVirtualAddressMap()* service, the OS will only be able to call runtime services in a virtual addressing mode. All runtime interfaces are non-blocking interfaces and can be called with interrupts disabled if desired.To ensure maximum compatibility with existing platforms it is recommended that all UEFI modules that comprise the Runtime Services be represented in the MemoryMap as a single EFI_MEMORY_DESCRIPTOR of Type EfiRuntimeServicesCode.

In all cases memory used by the runtime services must be reserved and not used by the OS. runtime services memory is always available to an UEFI function and will never be directly manipulated by the OS or its components. UEFI is responsible for defining the hardware resources used by runtime services, so the OS can synchronize with those resources when runtime service calls are made, or guarantee that the OS never uses those resources. See the table below for lists of the Runtime Services functions.

Table 2.2: UEFI Runtime Services

Name	**Description**
GetTime()	Returns the current time, time context, and time keeping capabilities.
SetTime()	Sets the current time and time context.
GetWakeupTime()	Returns the current wakeup alarm settings.
SetWakeupTime()	Sets the current wakeup alarm settings.
GetVariable()	Returns the value of a named variable.
GetNextVariableName()	Enumerates variable names.
SetVariable()	Sets, and if needed creates, a variable.
SetVirtualAddressMap()	Switches all runtime functions from physical to virtual addressing.
ConvertPointer()	Used to convert a pointer from physical to virtual addressing.

continues on next page

Table 2.2 – continued from previous page

Get Next High Monotonic Count	Subsumes the platform's monotonic counter functionality.
ResetSystem()	Resets all processors and devices and reboots the system.
Update Capsule	Passes capsules to the firmware with both virtual and physical mapping.
QueryCapsuleCapabilities()	Returns if the capsule can be supported via *UpdateCapsule()*.
QueryVariableInfo()	Returns information about the EFI variable store.

2.3 Calling Conventions

Unless otherwise stated, all functions defined in the UEFI specification are called through pointers in common, architecturally defined, calling onventions found in C compilers. Pointers to the various global UEFI functions are found in the EFI_RUNTIME_SERVICES and EFI_BOOT_SERVICES tables that are located via the system table. Pointers to other functions defined in this specification are located dynamically through device handles. In all cases, all pointers to UEFI functions are cast with the word EFIAPI . This allows the compiler for each architecture to supply the proper compiler keywords to achieve the needed calling conventions. When passing pointer arguments to Boot Services, Runtime Services, and Protocol Interfaces, the caller has the following responsibilities:

- It is the caller's responsibility to pass pointer parameters that reference physical memory locations. If a pointer is passed that does not point to a physical memory location (i.e., a memory mapped I/O region), the results are unpredictable and the system may halt.
- It is the caller's responsibility to pass pointer parameters with correct alignment. If an unaligned pointer is passed to a function, the results are unpredictable and the system may halt.
- It is the caller's responsibility to not pass in a NULL parameter to a function unless it is explicitly allowed. If a NULL pointer is passed to a function, the results are unpredictable and the system may hang.
- Unless otherwise stated, a caller should not make any assumptions regarding the state of pointer parameters if the function returns with an error.
- A caller may not pass structures that are larger than native size by value and these structures must be passed by reference (via a pointer) by the caller. Passing a structure larger than native width (4 bytes on supported 32-bit processors; 8 bytes on supported 64-bit processor instructions) on the stack will produce undefined results.

Calling conventions for supported 32-bit and supported 64-bit applications are described in more detail below. Any function or protocol may return any valid return code.

All public interfaces of a UEFI module must follow the UEFI calling convention. Public interfaces include the image entry point, UEFI event handlers, and protocol member functions. The type EFIAPI is used to indicate conformance to the calling conventions defined in this section. Non public interfaces, such as private functions and static library calls, are not required to follow the UEFI calling conventions and may be optimized by the compiler.

2.3.1 Data Types

See the table below which lists the common data types that are used in the interface definitions, and the following table, Modifiers for Common UEFI Data Types, lists their modifiers. Unless otherwise specified all data types are naturally aligned. Structures are aligned on boundaries equal to the largest internal datum of the structure and internal data are implicitly padded to achieve natural alignment.

The values of the pointers passed into or returned by the UEFI interfaces must provide natural alignment for the underlying types.

Common UEFI Data Types

Table 2.3: Common UEFI Data Types

Mnemonic	Description
BOOLEAN	Logical Boolean. 1-byte value containing a 0 for **FALSE** or a 1 for **TRUE**. Other values are undefined.
INTN	Signed value of native width. (4 bytes on supported 32-bit processor instructions, 8 bytes on supported 64-bit processor instructions, 16 bytes on supported 128-bit processor instructions)
UINTN	Unsigned value of native width. (4 bytes on supported 32-bit processor instructions, 8 bytes on supported 64-bit processor instructions, 16 bytes on supported 128-bit processor instructions)
INT8	1-byte signed value.
UINT8	1-byte unsigned value.
INT16	2-byte signed value.
UINT16	2-byte unsigned value.
INT32	4-byte signed value.
UINT32	4-byte unsigned value.
INT64	8-byte signed value.
UINT64	8-byte unsigned value.
INT128	16-byte signed value.
UINT128	16-byte unsigned value.
CHAR8	1-byte character. Unless otherwise specified, all 1-byte or ASCII characters and strings are stored in 8-bit ASCII encoding format, using the ISO-Latin-1 character set.
CHAR16	2-byte Character. Unless otherwise specified all characters and strings are stored in the UCS-2 encoding format as defined by Unicode 2.1 and ISO/IEC 10646 standards.
VOID	Undeclared type.
EFI_GUID	128-bit buffer containing a unique identifier value. Unless otherwise specified, aligned on a 64-bit boundary.
EFI_STATUS	Status code. Type UINTN.
EFI_HANDLE	A collection of related interfaces. Type VOID *.
EFI_EVENT	Handle to an event structure. Type VOID *.
EFI_LBA	Logical block address. Type UINT64.
EFI_TPL	Task priority level. Type UINTN.
EFI_MAC_ADDRESS	32-byte buffer containing a network Media Access Control address.
EFI_IPv4_ADDRESS	4-byte buffer. An IPv4 internet protocol address.
EFI_IPv6_ADDRESS	16-byte buffer. An IPv6 internet protocol address.
EFI_IP_ADDRESS	16-byte buffer aligned on a 4-byte boundary. An IPv4 or IPv6 internet protocol address.

continues on next page

Table 2.3 – continued from previous page

<Enumerated Type>	Element of a standard ANSI C *enum* type declaration. Type INT32.or UINT32. ANSI C does not define the size of sign of an enum so they should never be used in structures. ANSI C integer promotion rules make INT32 or UINT32 interchangeable when passed as an argument to a function.
sizeof (VOID *)	4 bytes on supported 32-bit processor instructions. 8 bytes on supported 64-bit processor instructions. 16 bytes on supported 128-bit processor.
Bitfields	Bitfields are ordered such that bit 0 is the least significant bit.

Table 2.4: Modifiers for Common UEFI Data Types

Mnemonic	**Description**
IN	Datum is passed to the function.
OUT	Datum is returned from the function.
OPTIONAL	Passing the datum to the function is optional, and a *NULL* may be passed if the value is not supplied.
CONST	Datum is read-only.
EFIAPI	Defines the calling convention for UEFI interfaces.

2.3.2 IA-32 Platforms

All functions are called with the C language calling convention. The general-purpose registers that are volatile across function calls are eax, ecx, and edx. All other general-purpose registers are nonvolatile and are preserved by the target function. In addition, unless otherwise specified by the function definition, all other registers are preserved.

Firmware boot ‘services and runtime services run in the following processor execution mode prior to the OS calling ExitBootServices():

- Uniprocessor, as described in chapter 8.4 of:
  - Intel 64 and IA-32 Architectures Software Developer’s Manual
  - Volume 3, System Programming Guide, Part 1
  - Order Number: 253668-033US, December 2009
  - See “Links to UEFI-Related Documents” (http://uefi.org/uefi) under the heading “Intel Processor Manuals.””
- Protected mode
- Paging mode may be enabled. If paging mode is enabled, PAE (Physical Address Extensions) mode is recommended. If paging mode is enabled, any memory space defined by the UEFI memory map is identity mapped (virtual address equals physical address). The mappings to other regions are undefined and may vary from implementation to implementation.
- Selectors are set to be flat and are otherwise not used
- Interrupts are enabled-though no interrupt services are supported other than the UEFI boot services timer functions (All loaded device drivers are serviced synchronously by “polling.”)
- Direction flag in EFLAGs is clear
- Other general purpose flag registers are undefined
- 128 KiB, or more, of available stack space
- The stack must be 16-byte aligned. Stack may be marked as non-executable in identity mapped page tables.

- Floating-point control word must be initialized to 0x027F (all exceptions masked, double-precision, round-to-nearest)
- Multimedia-extensions control word (if supported) must be initialized to 0x1F80 (all exceptions masked, round-to-nearest, flush to zero for masked underflow).
- CR0.EM must be zero
- CR0.TS must be zero

An application written to this specification may alter the processor execution mode, but the UEFI image must ensure firmware boot services and runtime services are executed with the prescribed execution environment.

After an Operating System calls ExitBootServices() , firmware boot services are no longer available and it is illegal to call any boot service. After ExitBootServices, firmware runtime services are still available and may be called with paging enabled and virtual address pointers if SetVirtualAddressMap() has been called describing all virtual address ranges used by the firmware runtime service. For an operating system to use any UEFI runtime services, it must:

- Preserve all memory in the memory map marked as runtime code and runtime data
- Call the runtime service functions, with the following conditions:
  - In protected mode
  - Paging may or may not be enabled, however if paging is enabled and SetVirtualAddressMap() has not been called, any memory space defined by the UEFI memory map is identity mapped (virtual address equals physical address), although the attributes of certain regions may not have all read, write, and execute attributes or be unmarked for purposes of platform protection. The mappings to other regions are undefined and may vary from implementation to implementation. See description of *SetVirtualAddressMap()* for details of memory map after this function has been called.
  - Direction flag in EFLAGs clear
  - 4 KiB, or more, of available stack space
  - The stack must be 16-byte aligned
  - Floating-point control word must be initialized to 0x027F (all exceptions masked, double-precision, round-to-nearest)
  - Multimedia-extensions control word (if supported) must be initialized to 0x1F80 (all exceptions masked, round-to-nearest, flush to zero for masked underflow)
  - CR0.EM must be zero
  - CR0.TS must be zero
  - Interrupts disabled or enabled at the discretion of the caller
- ACPI Tables loaded at boot time can be contained in memory of type EfiACPIReclaimMemory (recommended) or EfiACPIMemoryNVS . ACPI FACS must be contained in memory of type EfiACPIMemoryNVS.
- The system firmware must not request a virtual mapping for any memory descriptor of type EfiACPIReclaimMemory or EfiACPIMemoryNVS .
- EFI memory descriptors of type EfiACPIReclaimMemory and EfiACPIMemoryNVS must be aligned on a 4 KiB boundary and must be a multiple of 4 KiB in size.
- Any UEFI memory descriptor that requests a virtual mapping via the EFI_MEMORY_DESCRIPTOR having the EFI_MEMORY_RUNTIME bit set must be aligned on a 4 KiB boundary and must be a multiple of 4 KiB in size.
- An ACPI Memory Op-region must inherit cacheability attributes from the UEFI memory map. If the system memory map does not contain cacheability attributes, the ACPI Memory Op-region must inherit its cacheability

attributes from the ACPI name space. If no cacheability attributes exist in the system memory map or the ACPI name space, then the region must be assumed to be non-cacheable.

- ACPI tables loaded at runtime must be contained in memory of type EfiACPIMemoryNVS . The cacheability attributes for ACPI tables loaded at runtime should be defined in the UEFI memory map. If no information about the table location exists in the UEFI memory map, cacheability attributes may be obtained from ACPI memory descriptors. If no information about the table location exists in the UEFI memory map or ACPI memory descriptors, the table is assumed to be non-cached.
- In general, UEFI Configuration Tables loaded at boot time (e.g., SMBIOS table) can be contained in memory of type EfiRuntimeServicesData (recommended), EfiBootServicesData , EfiACPIReclaimMemory or EfiACPIMemoryNVS . Tables loaded at runtime must be contained in memory of type EfiRuntimeServicesData (recommended) or EfiACPIMemoryNVS .

Note: *Previous EFI specifications allowed ACPI tables loaded at runtime to be in the EfiReservedMemoryType and there was no guidance provided for other EFI Configuration Tables. EfiReservedMemoryType is not intended to be used for the storage of any EFI Configuration Tables. Also, only OSes conforming to the UEFI Specification are guaranteed to handle SMBIOS table in memory of type EfiBootServicesData.*

2.3.2.1 Handoff State

When a 32-bit UEFI OS is loaded, the system firmware hands off control to the OS in flat 32-bit mode. All descriptors are set to their 4GiB limits so that all of memory is accessible from all segments.

The Figure below (*Stack After AddressOfEntryPoint Called, IA-32*)shows the stack after AddressOfEntryPoint in the image's PE32+ header has been called on supported 32-bit systems. All UEFI image entry points take two parameters. These are the image handle of the UEFI image, and a pointer to the EFI System Table.

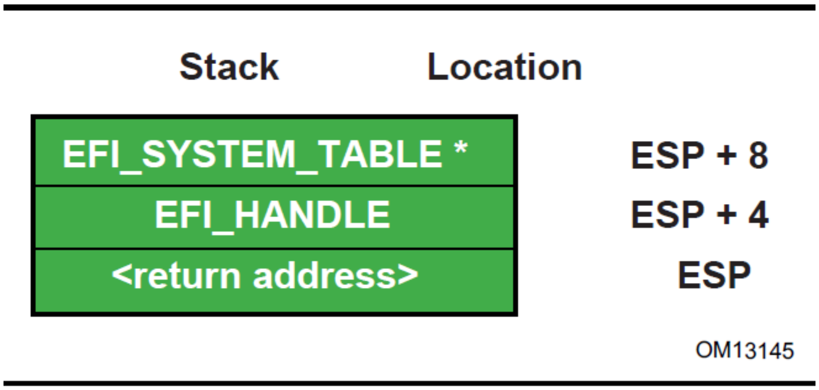

Fig. 2.2: Stack After AddressOfEntryPoint Called, IA-32

2.3.2.2 Calling Convention

All functions are called with the C language calling convention. The general-purpose registers that are volatile across function calls are eax , ecx , and edx . All other general-purpose registers are nonvolatile and are preserved by the target function.

In addition, unless otherwise specified by the function definition, all other CPU registers (including MMX and XMM) are preserved.

The floating point status register is not preserved by the target function. The floating point control register and MMX control register are saved by the target function.

If the return value is a float or a double, the value is returned in ST(0).

2.3.3 Intel®Itanium®-Based Platforms

UEFI executes as an extension to the SAL execution environment with the same rules as laid out by the SAL specification.

During boot services time the processor is in the following execution mode:

- Uniprocessor, as detailed in chapter 13.1.2 of:
  - Intel Itanium Architecture Software Developer's Manual
  - Volume 2: System Architecture
  - Revision 2.2
  - January 2006
  - See "Links to UEFI-Related Documents" (http://uefi.org/uefi) under the heading "Intel Itanium Documentation".
  - Document Number: 245318-005
- Physical mode
- 128 KiB, or more, of available stack space
- 16 KiB, or more, of available backing store space
  - FPSR.traps: Set to all 1's (all exceptions disabled)
  - FPSR.sf0:
- .pc: Precision Control - 11b (extended precision)
- .rc: Rounding Control - 0 (round to nearest)
- .wre: Widest Range Exponent - 0 (IEEE mode)
- .ftz: Flush-To-Zero mode - 0 (off)
  - FPSR.sf1:
- .td: Traps Disable = 1 (traps disabled)
- .pc: Precision Control - 11b (extended precision)
- .rc: Rounding Control - 0 (round to nearest)
- wreWidest Range Exponent - 1 (full register exponent range)
- ftz Flush-To-Zero mode - 0 (off)
  - FPSR.sf2,3:
- .td Traps Disable = 1 (traps disabled)
- pc: Precision Control - 11b (extended precision)
- .rc: Rounding Control - 0 (round to nearest)
- .wre: Widest Range Exponent - 0 (IEEE mode)
- .ftz: Flush-To-Zero mode - 0 (off)

An application written to this specification may alter the processor execution mode, but the UEFI image must ensure firmware boot services and runtime services are executed with the prescribed execution environment.

After an Operating System calls ExitBootServices(), firmware boot services are no longer available and it is illegal to call any boot service. After ExitBootServices, firmware runtime services are still available When calling runtime services, paging may or may not be enabled, however if paging is enabled and SetVirtualAddressMap() has not been called, any memory space defined by the UEFI memory map is identity mapped (virtual address equals physical address). The mappings to other regions are undefined and may vary from implementation to implementation. See description of *SetVirtualAddressMap()* for details of memory map after this function has been called. After ExitBootServices(), runtime service functions may be called with interrupts disabled or enabled at the discretion of the caller.

- ACPI Tables loaded at boot time can be contained in memory of type EfiACPIReclaimMemory (recommended) or EfiACPIMemoryNVS. CPI FACS must be contained in memory of type EfiACPIMemoryNVS.
- The system firmware must not request a virtual mapping for any memory descriptor of type EfiACPIReclaimMemory or EfiACPIMemoryNVS.
- EFI memory descriptors of type EfiACPIReclaimMemory and EfiACPIMemoryNVS. must be aligned on an 8 KiB boundary and must be a multiple of 8 KiB in size.
- Any UEFI memory descriptor that requests a virtual mapping via the EFI_MEMORY_DESCRIPTOR having the EFI_MEMORY_RUNTIME bit set must be aligned on an 8 KiB boundary and must be a multiple of 8 KiB in size.
- An ACPI Memory Op-region must inherit cacheability attributes from the UEFI memory map. If the system memory map does not contain cacheability attributes the ACPI Memory Op-region must inherit its cacheability attributes from the ACPI name space. If no cacheability attributes exist in the system memory map or the ACPI name space, then the region must be assumed to be non-cacheable.
- ACPI tables loaded at runtime must be contained in memory of type EfiACPIMemoryNVS . The cacheability attributes for ACPI tables loaded at runtime should be defined in the UEFI memory map. If no information about the table location exists in the UEFI memory map, cacheability attributes may be obtained from ACPI memory descriptors. If no information about the table location exists in the UEFI memory map or ACPI memory descriptors, the table is assumed to be non-cached.
- In general, Configuration Tables loaded at boot time (e.g., SMBIOS table) can be contained in memory of type EfiRuntimeServicesData (recommended), EfiBootServicesData, EfiACPIReclaimMemory or EfiACPIMemoryNVS. Tables loaded at runtime must be contained in memory of type EfiRuntimeServicesData (recommended) or EfiACPIMemoryNVS.

Note: *Previous EFI specifications allowed ACPI tables loaded at runtime to be in the* EfiReservedMemoryType *and there was no guidance provided for other EFI Configuration Tables.* EfiReservedMemoryType *is not intended to be used by firmware. Also, only OSes conforming to the UEFI Specification are guaranteed to handle SMBIOS table in memory of type* EfiBootServicesData.

Refer to the IA-64 System Abstraction Layer Specification (*Appendix Q — References*) for details.

UEFI procedures are invoked using the P64 C calling conventions defined for Intel ® Itanium ® -based applications. Refer to the document 64 Bit Runtime Architecture and Software Conventions for IA-64 (*Appendix Q — References*) for more information.

2.3.3.1 Handoff State

UEFI uses the standard P64 C calling conventions that are defined for Itanium-based operating systems. The Figure below shows the stack after ImageEntryPoint has been called on Itanium-based systems. The arguments are also stored in registers: out0 contains EFI_HANDLE and out1 contains the address of the EFI_SYSTEM_TABLE . The gp for the UEFI Image will have been loaded from the plabel pointed to by the AddressOfEntryPoint in the image's PE32+ header. All UEFI image entry points take two parameters. These are the image handle of the image, and a pointer to the System Table.

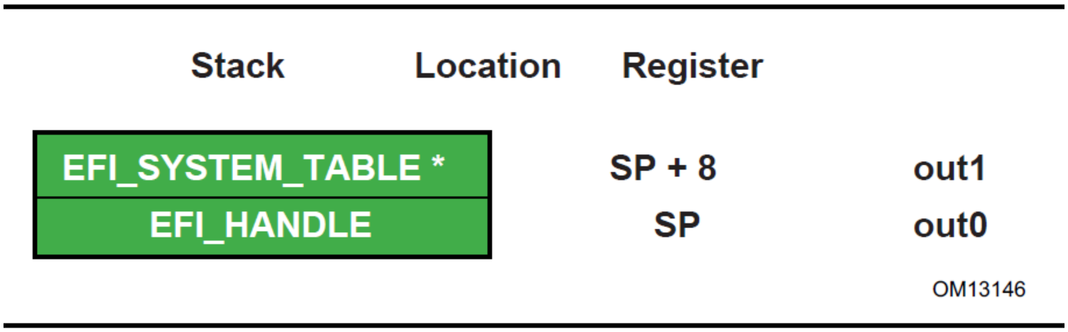

Fig. 2.3: Stack after AddressOfEntryPoint Called, Itanium-based Systems

The SAL specification (*Appendix Q — References*) defines the state of the system registers at boot handoff. The SAL specification also defines which system registers can only be used after UEFI boot services have been properly terminated.

2.3.3.2 Calling Convention

UEFI executes as an extension to the SAL execution environment with the same rules as laid out by the SAL specification. UEFI procedures are invoked using the P64 C calling conventions defined for Intel®Itanium®-based applications. Refer to the document 64 Bit Runtime Architecture and Software Conventions for IA-64 (see the index appendix for more information).

For floating point, functions may only use the lower 32 floating point registers Return values appear in f8-f15 registers. Single, double, and extended values are all returned using the appropriate format. Registers f6-f7 are local registers and are not preserved for the caller. All other floating point registers are preserved. Note that, when compiling UEFI programs, a special switch will likely need to be specified to guarantee that the compiler does not use f32-f127, which are not normally preserved in the regular calling convention for Itanium. A procedure using one of the preserved floating point registers must save and restore the caller's original contents without generating a NaT consumption fault.

Floating point arguments are passed in f8-f15 registers when possible. Parameters beyond the registers appear in memory, as explained in Section 8.5 of the Itanium Software Conventions and Runtime Architecture Guide. Within the called function, these are local registers and are not preserved for the caller. Registers f6-f7 are local registers and are not preserved for the caller. All other floating point registers are preserved. Note that, when compiling UEFI programs, a special switch will likely need to be specified to guarantee that the compiler does not use f32-f127, which are not normally preserved in the regular calling convention for Itanium. A procedure using one of the preserved floating point registers must save and restore the caller's original contents without generating a NaT consumption fault.

The floating point status register must be preserved across calls to a target function. Flags fields in SF1,2,3 are not preserved for the caller. Flags fields in SF0 upon return will reflect the value passed in, and with bits set to 1 corresponding to any IEEE exceptions detected on non-speculative floating-point operations executed as part of the callee.

Floating-point operations executed by the callee may require software emulation. The caller must be prepared to handle FP Software Assist (FPSWA) interruptions. Callees should not raise IEEE traps by changing FPSR.traps bits to 0 and then executing floating-point operations that raise such traps.

2.3.4 x64 Platforms

All functions are called with the C language calling convention. *Detailed Calling Conventions* for more detail.

During boot services time the processor is in the following execution mode:

- Uniprocessor, as described in chapter 8.4 of:
  - Intel 64 and IA-32 Architectures Software Developer's Manual, Volume 3, System Programming Guide, Part 1, Order Number: 253668-033US, December 2009
  - See "Links to UEFI-Related Documents" (http://uefi.org/uefi) under the heading "Intel Processor Manuals".
- Long mode, in 64-bit mode
- Paging mode is enabled and any memory space defined by the UEFI memory map is identity mapped (virtual address equals physical address), although the attributes of certain regions may not have all read, write, and execute attributes or be unmarked for purposes of platform protection. The mappings to other regions, such as those for unaccepted memory, are undefined and may vary from implementation to implementation.
- Selectors are set to be flat and are otherwise not used.
- Interrupts are enabled-though no interrupt services are supported other than the UEFI boot services timer functions (All loaded device drivers are serviced synchronously by "polling.")
- Direction flag in EFLAGs is clear
- Other general purpose flag registers are undefined
- 128 KiB, or more, of available stack space
- The stack must be 16-byte aligned. Stack may be marked as non-executable in identity mapped page tables.
- Floating-point control word must be initialized to 0x037F (all exceptions masked, double-extended-precision, round-to-nearest)
- Multimedia-extensions control word (if supported) must be initialized to 0x1F80 (all exceptions masked, round-to-nearest, flush to zero for masked underflow).
- CR0.EM must be zero
- CR0.TS must be zero

For an operating system to use any UEFI runtime services, it must:

- Preserve all memory in the memory map marked as runtime code and runtime data
- Call the runtime service functions, with the following conditions:
- In long mode, in 64-bit mode
- Paging enabled
- All selectors set to be flat with virtual = physical address. If the UEFI OS loader or OS used SetVirtualAddressMap() to relocate the runtime services in a virtual address space, then this condition does not have to be met. See description *SetVirtualAddressMap()* for details of memory map after this function has been called.
- Direction flag in EFLAGs clear
- 4 KiB, or more, of available stack space
- The stack must be 16-byte aligned
- Floating-point control word must be initialized to 0x037F (all exceptions masked, double-extended-precision, round-to-nearest)

- Multimedia-extensions control word (if supported) must be initialized to 0x1F80 (all exceptions masked, round-to-nearest, flush to zero for masked underflow)
- CR0.EM must be zero
- CR0.TS must be zero
- Interrupts may be disabled or enabled at the discretion of the caller.
- ACPI Tables loaded at boot time can be contained in memory of type EfiACPIReclaimMemory (recommended) or EfiACPIMemoryNVS . ACPI FACS must be contained in memory of type EfiACPIMemoryNVS .
- The system firmware must not request a virtual mapping for any memory descriptor of type EfiACPIReclaimMemory or EfiACPIMemoryNVS .
- EFI memory descriptors of type EfiACPIReclaimMemory and EfiACPIMemoryNVS must be aligned on a 4 KiB boundary and must be a multiple of 4 KiB in size.
- Any UEFI memory descriptor that requests a virtual mapping via the EFI_MEMORY_DESCRIPTOR having the EFI_MEMORY_RUNTIME bit set must be aligned on a 4 KiB boundary and must be a multiple of 4 KiB in size.
- An ACPI Memory Op-region must inherit cacheability attributes from the UEFI memory map. If the system memory map does not contain cacheability attributes, the ACPI Memory Op-region must inherit its cacheability attributes from the ACPI name space. If no cacheability attributes exist in the system memory map or the ACPI name space, then the region must be assumed to be non-cacheable.
- ACPI tables loaded at runtime must be contained in memory of type EfiACPIMemoryNVS . The cacheability attributes for ACPI tables loaded at runtime should be defined in the UEFI memory map. If no information about the table location exists in the UEFI memory map, cacheability attributes may be obtained from ACPI memory descriptors. If no information about the table location exists in the UEFI memory map or ACPI memory descriptors, the table is assumed to be non-cached.
- In general, UEFI Configuration Tables loaded at boot time (e.g., SMBIOS table) can be contained in memory of type EfiRuntimeServicesData (recommended), EfiBootServicesData , EfiACPIReclaimMemory or EfiACPIMemoryNVS . Tables loaded at runtime must be contained in memory of type EfiRuntimeServicesData (recommended) or EfiACPIMemoryNVS.

Note: *Previous EFI specifications allowed ACPI tables loaded at runtime to be in the* EfiReservedMemoryType *and there was no guidance provided for other EFI Configuration Tables.* EfiReservedMemoryType *is not intended to be used by firmware. Also, only OSes conforming to the UEFI Specification are guaranteed to handle SMBIOS table in memory of type* EfiBootServicesData.

2.3.4.1 Handoff State

Rcx - EFI_HANDLE

Rdx - EFI_SYSTEM_TABLE*

RSP - <return address>

2.3.4.2 Detailed Calling Conventions

The caller passes the first four integer arguments in registers. The integer values are passed from left to right in Rcx, Rdx, R8, and R9 registers. The caller passes arguments five and above onto the stack. All arguments must be right-justified in the register in which they are passed. This ensures the callee can process only the bits in the register that are required.

The caller passes arrays and strings via a pointer to memory allocated by the caller. The caller passes structures and unions of size 8, 16, 32, or 64 bits as if they were integers of the same size. The caller is not allowed to pass structures and unions of other than these sizes and must pass these unions and structures via a pointer.

The callee must dump the register parameters into their shadow space if required. The most common requirement is to take the address of an argument.

If the parameters are passed through varargs then essentially the typical parameter passing applies, including spilling the fifth and subsequent arguments onto the stack. The callee must dump the arguments that have their address taken.

Return values that fix into 64-bits are returned in the Rax register. If the return value does not fit within 64-bits, then the caller must allocate and pass a pointer for the return value as the first argument, Rcx. Subsequent arguments are then shifted one argument to the right, so for example argument one would be passed in Rdx. User-defined types to be returned must be 1,2,4,8,16,32, or 64 bits in length.

The registers Rax, Rcx Rdx R8, R9, R10, R11, and XMM0-XMM5 are volatile and are, therefore, destroyed on function calls.

The registers RBX, RBP, RDI, RSI, R12, R13, R14, R15, and XMM6-XMM15 are considered nonvolatile and must be saved and restored by a function that uses them.

Function pointers are pointers to the label of the respective function and don't require special treatment.

A caller must always call with the stack 16-byte aligned.

For MMX, XMM and floating-point values, return values that can fit into 64-bits are returned through RAX (including MMX types). However, XMM 128-bit types, floats, and doubles are returned in XMM0. The floating point status register is not saved by the target function. Floating-point and double-precision arguments are passed in XMM0 - XMM3 (up to 4) with the integer slot (RCX, RDX, R8, and R9) that would normally be used for that cardinal slot being ignored (see example) and vice versa. XMM types are never passed by immediate value but rather a pointer will be passed to memory allocated by the caller. MMX types will be passed as if they were integers of the same size. Callees must not unmask exceptions without providing correct exception handlers.

In addition, unless otherwise specified by the function definition, all other CPU registers (including MMX and XMM) are preserved.

2.3.4.3 Enabling Paging or Alternate Translations in an Application

Boot Services define an execution environment where paging is not enabled (supported 32-bit) or where translations are enabled but mapped virtual equal physical (x64) and this section will describe how to write an application with alternate translations or with paging enabled. Some Operating Systems require the OS Loader to be able to enable OS required translations at Boot Services time.

If a UEFI application uses its own page tables, GDT or IDT, the application must ensure that the firmware executes with each supplanted data structure. There are two ways that firmware conforming to this specification can execute when the application has paging enabled.

- Explicit firmware call
- Firmware preemption of application via timer event

An application with translations enabled can restore firmware required mapping before each UEFI call. However the possibility of preemption may require the translation enabled application to disable interrupts while alternate translations are enabled. It's legal for the translation enabled application to enable interrupts if the application catches the interrupt and restores the EFI firmware environment prior to calling the UEFI interrupt ISR. After the UEFI ISR context is executed it will return to the translation enabled application context and restore any mappings required by the application.

2.3.5 AArch32 Platforms

All functions are called with the C language calling convention specified in *Detailed Calling Convention* . In addition, the invoking OSs can assume that unaligned access support is enabled if it is present in the processor.

During boot services time the processor is in the following execution mode:

- Unaligned access should be enabled if supported; Alignment faults are enabled otherwise.
- Uniprocessor.
- A privileged mode.
- The MMU is enabled (CP15 c1 System Control Register (SCTLR) SCTLR.M=1) and any RAM defined by the UEFI memory map is identity mapped (virtual address equals physical address). The mappings to other regions are undefined and may vary from implementation to implementation
- The core will be configured as follows (common across all processor architecture revisions):
  - MMU enabled
  - Instruction and Data caches enabled
  - Access flag disabled
  - Translation remap disabled
  - Little endian mode
  - Domain access control mechanism (if supported) will be configured to check access permission bits in the page descriptor
  - Fast Context Switch Extension (FCSE) must be disabled

  This will be achieved by:

  - Configuring the CP15 c1 System Control Register (SCTLR) as follows: I=1, C=1, B=0, TRE=0, AFE=0, M=1
  - Configuring the CP15 c3 Domain Access Control Register (DACR) to 0x33333333.
  - Configuring the CP15 c1 System Control Register (SCTLR), A=1 on ARMv4 and ARMv5, A=0, U=1 on ARMv6 and ARMv7.

  The state of other system control register bits is not dictated by this specification.
- Implementations of boot services will enable architecturally manageable caches and TLBs i.e., those that can be managed directly using CP15 operations using mechanisms and procedures defined in the ARM Architecture Reference Manual. They should not enable caches requiring platform information to manage or invoke non-architectural cache/TLB lockdown mechanisms
- MMU configuration — Implementations must use only 4k pages and a single translation base register. On devices supporting multiple translation base registers, TTBR0 must be used solely. The binding does not mandate whether page tables are cached or un-cached.

  - On processors implementing the ARMv4 through ARMv6K architecture definitions, the core is additionally configured to disable extended page tables support, if present.

    This will be achieved by configuring the CP15 c1 System Control Register (SCTLR) as follows: XP=0

  - On processors implementing the ARMv7 and later architecture definitions, the core will be configured to enable the extended page table format and disable the TEX remap mechanism.

    This will be achieved by configuring the CP15 c1 System Control Register (SCTLR) as follows: XP=1, TRE=0

- Interrupts are enabled-though no interrupt services are supported other than the UEFI boot services timer functions (All loaded device drivers are serviced synchronously by "polling.")
- 128 KiB or more of available stack space

For an operating system to use any runtime services, it must:

- Preserve all memory in the memory map marked as runtime code and runtime data
- Call the runtime service functions, with the following conditions:
  - In a privileged mode.
  - The system address regions described by all the entries in the EFI memory map that have the EFI_MEMORY_RUNTIME bit set must be identity mapped as they were for the EFI boot environment. If the OS Loader or OS used SetVirtualAddressMap() to relocate the runtime services in a virtual address space, then this condition does not have to be met. See description of SetVirtualAddressMap() for details of memory map after this function has been called.
  - The processor must be in a mode in which it has access to the system address regions specified in the EFI memory map with the EFI_MEMORY_RUNTIME bit set.
  - 4 KiB, or more, of available stack space
  - Interrupts may be disabled or enabled at the discretion of the caller

An application written to this specification may alter the processor execution mode, but the invoking OS must ensure firmware boot services and runtime services are executed with the prescribed execution environment.

If ACPI is supported:

- ACPI Tables loaded at boot time can be contained in memory of type EfiACPIReclaimMemory (recommended) or EfiACPIMemoryNVS. ACPI FACS must be contained in memory of type EfiACPIMemoryNVS
- The system firmware must not request a virtual mapping for any memory descriptor of type EfiACPIReclaimMemory or EfiACPIMemoryNVS.
- EFI memory descriptors of type EfiACPIReclaimMemory and EfiACPIMemoryNVS must be aligned on a 4 KiB boundary and must be a multiple of 4 KiB in size.
- Any UEFI memory descriptor that requests a virtual mapping via the EFI_MEMORY_DESCRIPTOR having the EFI_MEMORY_RUNTIME bit set must be aligned on a 4 KiB boundary and must be a multiple of 4 KiB in size.
- An ACPI Memory Op-region must inherit cacheability attributes from the UEFI memory map. If the system memory map does not contain cacheability attributes, the ACPI Memory Op-region must inherit its cacheability attributes from the ACPI name space. If no cacheability attributes exist in the system memory map or the ACPI name space, then the region must be assumed to be non-cacheable.
- ACPI tables loaded at runtime must be contained in memory of type EfiACPIMemoryNVS. The cacheability attributes for ACPI tables loaded at runtime should be defined in the UEFI memory map. If no information about the table location exists in the UEFI memory map, cacheability attributes may be obtained from ACPI

memory descriptors. If no information about the table location exists in the UEFI memory map or ACPI memory descriptors, the table is assumed to be non-cached.

- In general, UEFI Configuration Tables loaded at boot time (e.g., SMBIOS table) can be contained in memory of type EfiRuntimeServicesData (recommended), EfiBootServicesData , EfiACPIReclaimMemory or EfiACPIMemoryNVS. Tables loaded at runtime must be contained in memory of type EfiRuntimeServicesData (recommended) or EfiACPIMemoryNVS.

Note: *Previous EFI specifications allowed ACPI tables loaded at runtime to be in the EfiReservedMemoryType and there was no guidance provided for other EFI Configuration Tables. EfiReservedMemoryType is not intended to be used by firmware. Also, only OSes conforming to the UEFI Specification are guaranteed to handle SMBIOS table in memory of type EfiBootServicesData.*

2.3.5.1 Handoff State

R0 - EFI_HANDLE

R1 - EFI_SYSTEM_TABLE*

R14 - Return Address

2.3.5.2 Enabling Paging or Alternate Translations in an Application

Boot Services define a specific execution environment. This section will describe how to write an application that creates an alternative execution environment. Some Operating Systems require the OS Loader to be able to enable OS required translations at Boot Services time, and make other changes to the UEFI defined execution environment.

If a UEFI application uses its own page tables, or other processor state, the application must ensure that the firmware executes with each supplanted functionality. There are two ways that firmware conforming to this specification can execute in this alternate execution environment:

- Explicit firmware call
- Firmware preemption of application via timer event

An application with an alternate execution environment can restore the firmware environment before each UEFI call. However the possibility of preemption may require the alternate execution-enabled application to disable interrupts while the alternate execution environment is active. It's legal for the alternate execution environment enabled application to enable interrupts if the application catches the interrupt and restores the EFI firmware environment prior to calling the UEFI interrupt ISR. After the UEFI ISR context is executed it will return to the alternate execution environment enabled application context.

An alternate execution environment created by a UEFI application must not change the semantics or behavior of the MMU configuration created by the UEFI firmware prior to invoking ExitBootServices(), including the bit layout of the page table entries.

After an OS loader calls ExitBootServices() it should immediately configure the exception vector to point to appropriate code.

2.3.5.3 Detailed Calling Convention

The base calling convention for the ARM binding is defined here:

Procedure Call Standard for the ARM Architecture V2.06 (or later)

See "Links to UEFI-Related Documents" (http://uefi.org/uefi) under the heading "Arm Architecture Base Calling Convention".

This binding further constrains the calling convention in these ways:

- Calls to UEFI defined interfaces must be done assuming that the target code requires the ARM instruction set state. Images are free to use other instruction set states except when invoking UEFI interfaces.
- Floating point, SIMD, vector operations and other instruction set extensions must not be used.
- Only little endian operation is supported.
- The stack will maintain 8 byte alignment as described in the AAPCS for public interfaces.
- Use of coprocessor registers for passing call arguments must not be used
- Structures (or other types larger than 64-bits) must be passed by reference and not by value
- The EFI ARM platform binding defines register r9 as an additional callee-saved variable register.

2.3.6 AArch64 Platforms

AArch64 UEFI will only execute 64-bit ARM code, as the ARMv8 architecture does not allow for the mixing of 32-bit and 64-bit code at the same privilege level.

All functions are called with the C language calling convention specified in Detailed calling Convention section below. During boot services only a single processor is used for execution. All secondary processors must be either powered off or held in a quiescent state.

The primary processor is in the following execution mode:

- Unaligned access must be enabled.
- Use the highest 64 bit non secure privilege level available; Non-secure EL2 (Hyp) or Non-secure EL1(Kernel).
- The MMU is enabled and any RAM defined by the UEFI memory map is identity mapped (virtual address equals physical address). The mappings to other regions are undefined and may vary from implementation to implementation
- The core will be configured as follows:
  - MMU enabled
  - Instruction and Data caches enabled
  - Little endian mode
  - Stack Alignment Enforced
  - NOT Top Byte Ignored
  - Valid Physical Address Space
  - 4K Translation Granule

This will be achieved by:

1. Configuring the System Control Register SCTLR_EL2 or SCTLR_EL1:

- EE=0, I=1, SA=1, C=1, A=0, M=1

2. Configuring the appropriate Translation Control Register:

- TCR_EL2
  - TBI=0
  - PS must contain the valid Physical Address Space Size.
  - TG0=00
- TCR_EL1
  - TBI0=0
  - IPS must contain the valid Intermediate Physical Address Space Size.
  - TG0=00

Note: *The state of other system control register bits is not dictated by this specification.*

- All floating point traps and exceptions will be disabled at the relevant exception levels (FPCR=0, CPACR_EL1.FPEN=11, CPTR_EL2.TFP=0). This implies that the FP unit will be enabled by default.
- Implementations of boot services will enable architecturally manageable caches and TLBs i.e., those that can be managed directly using implementation independent registers using mechanisms and procedures defined in the ARM Architecture Reference Manual. They should not enable caches requiring platform information to manage or invoke non-architectural cache/TLB lockdown mechanisms.
- MMU configuration: Implementations must use only 4k pages and a single translation base register. On devices supporting multiple translation base registers, TTBR0 must be used solely. The binding does not mandate whether page tables are cached or un-cached.
- Interrupts are enabled, though no interrupt services are supported other than the UEFI boot services timer functions (All loaded device drivers are serviced synchronously by "polling"). All UEFI interrupts must be routed to the IRQ vector only.
- The architecture generic timer must be initialized and enabled. The Counter Frequency register (CNTFRQ) must be programmed with the timer frequency. Timer access must be provided to non-secure EL1 and EL0 by setting bits EL1PCTEN and EL1PCEN in register CNTHCTL_EL2.
- The system firmware is not expected to initialize EL2 registers that do not have an architectural reset value, except in cases where firmware itself is running at EL2 and needs to do so.
- 128 KiB or more of available stack space
- The ARM architecture allows mapping pages at a variety of granularities, including 4KiB and 64KiB. If a 64KiB physical page contains any 4KiB page with any of the following types listed below, then all 4KiB pages in the 64KiB page must use identical ARM Memory Page Attributes (as described in *Map: EFI Cacheability Attributes to AArch64Memory Types*):

  – EfiRuntimeServicesCode

  – EfiRuntimeServicesData

  – EfiReserved

  – EfiACPIMemoryNVS

  Mixed attribute mappings within a larger page are not allowed.

Note: *This constraint allows a 64K paged based Operating System to safely map runtime services memory*.

For an operating system to use any runtime services, Runtime services must:

- Support calls from either the EL1 or the EL2 exception levels.
- Once called, simultaneous or nested calls from EL1 and EL2 are not permitted.

Note: *Sequential, non-overlapping, calls from EL1 and EL2 are permitted.*

Runtime services are permitted to make synchronous SMC and HVC calls into higher exception levels.

Note: *These rules allow Boot Services to start at EL2, and Runtime services to be assigned to an EL1 Operating System. In this case a call to SetVirtualAddressMap()is expected to provided an EL1 appropriate set of mappings.*

For an operating system to use any runtime services, it must:

- Enable unaligned access support.
- Preserve all memory in the memory map marked as runtime code and runtime data
- Call the runtime service functions, with the following conditions:
  - From either EL1 or EL2 exception levels.
  - Consistently call runtime services from the same exception level. Sharing of runtime services between different exception levels is not permitted.
  - Runtime services must only be assigned to a single operating system or hypervisor. They must not be shared between multiple guest operating systems.
  - The system address regions described by all the entries in the EFI memory map that have the EFI_MEMORY_RUNTIME bit set must be identity mapped as they were for the EFI boot environment. If the OS Loader or OS used SetVirtualAddressMap() to relocate the runtime services in a virtual address space, then this condition does not have to be met. See description of SetVirtualAddressMap() for details of memory map after this function has been called.
  - The processor must be in a mode in which it has access to the system address regions specified in the EFI memory map with the EFI_MEMORY_RUNTIME bit set.
  - 8 KiB, or more, of available stack space.
  - The stack must be 16-byte aligned (128-bit).
  - Interrupts may be disabled or enabled at the discretion of the caller.

An application written to this specification may alter the processor execution mode, but the invoking OS must ensure firmware boot services and runtime services are executed with the prescribed execution environment.

If ACPI is supported :

- ACPI Tables loaded at boot time can be contained in memory of type EfiACPIReclaimMemory (recommended) or EfiACPIMemoryNVS.
- ACPI FACS must be contained in memory of type EfiACPIMemoryNVS. The system firmware must not request a virtual mapping for any memory descriptor of type EfiACPIReclaimMemory or EfiACPIMemoryNVS.
- EFI memory descriptors of type EfiACPIReclaimMemory and EfiACPIMemoryNVS must be aligned on a 4 KiB boundary and must be a multiple of 4 KiB in size.
- Any UEFI memory descriptor that requests a virtual mapping via the EFI_MEMORY_DESCRIPTOR having the EFI_MEMORY_RUNTIME bit set must be aligned on a 4 KiB boundary and must be a multiple of 4 KiB in size.
- An ACPI Memory Op-region must inherit cacheability attributes from the UEFI memory map. If the system memory map does not contain cacheability attributes, the ACPI Memory Op-region must inherit its cacheability attributes from the ACPI name space. If no cacheability attributes exist in the system memory map or the ACPI name space, then the region must be assumed to be non-cacheable.
- ACPI tables loaded at runtime must be contained in memory of type EfiACPIMemoryNVS. The cacheability attributes for ACPI tables loaded at runtime should be defined in the UEFI memory map. If no information about the table location exists in the UEFI memory map, cacheability attributes may be obtained from ACPI

memory descriptors. If no information about the table location exists in the UEFI memory map or ACPI memory descriptors, the table is assumed to be non-cached.

- In general, UEFI Configuration Tables loaded at boot time (e.g., SMBIOS table) can be contained in memory of type EfiRuntimeServicesData (recommended), EfiBootServicesdata , EfiACPIReclaimMemory or EfiACPIMemoryNVS. Tables loaded at runtime must be contained in memory of type EfiRuntimeServicesData (recommended) or EfiACPIMemoryNVS.

Note: *Previous EFI specifications allowed ACPI tables loaded at runtime to be in the* EfiReservedMemoryType *and there was no guidance provided for other EFI Configuration Tables.* EfiReservedMemoryType *is not intended to be used by firmware. UEFI 2.0 clarified the situation moving forward. Also, only OSes conforming to UEFI Specification are guaranteed to handle SMBIOS table in memory of type* EfiBootServiceData.

2.3.6.1 Memory types

Table 2.5: Map: EFI Cacheability Attributes to AArch64Memory Types

EFI Memory Type	ARM Memory Type: MAIR attribute encoding Attr<n> [7:4] [3:0]	ARM Memory Type: Meaning
EFI_MEMORY_UC (Not cacheable)	0000 0000	Device-nGnRnE (Device non-Gathering, non-Reordering, no Early Write Acknowledgement)
EFI_MEMORY_WC (Write combine)	0100 0100	Normal Memory Outer non-cacheable Inner non-cacheable
EFI_MEMORY_WT (Write through)	1011 1011	Normal Memory Outer Write-through non-transient Inner Write-through non-transient
EFI_MEMORY_WB (Write back)	1111 1111	Normal Memory Outer Write-back non-transient Inner Write-back non-transient
EFI_MEMORY_UCE		Not used or defined

Table 2.6: Map: UEFI Permission Attributes to ARM Paging Attributes

EFI Memory Type	ARM Paging Attributes
EFI_MEMORY_XP	EL2 translation regime: XN Execute never EL1/0 translation regime: UXN Unprivileged execute never PXN Privileged execute never
EFI_MEMORY_RO	Read only access AP[2]=1
EFI_MEMORY_RP EFI_MEMORY_WP	Not used or defined

2.3.6.2 Handoff State

X0 - EFI_HANDLE

X1 - EFI_SYSTEM_TABLE

X30 - Return Address

2.3.6.3 Enabling Paging or Alternate Translations in an Application

Boot Services define a specific execution environment. This section will describe how to write an application that creates an alternative execution environment. Some Operating Systems require the OS Loader to be able to enable OS required translations at Boot Services time, and make other changes to the UEFI defined execution environment.

If a UEFI application uses its own page tables, or other processor state, the application must ensure that the firmware executes with each supplanted functionality. There are two ways that firmware conforming to this specification can execute in this alternate execution environment:

- Explicit firmware call
- Firmware preemption of application via timer event

An application with an alternate execution environment can restore the firmware environment before each UEFI call. However the possibility of preemption may require the alternate execution-enabled application to disable interrupts while the alternate execution environment is active. It's legal for the alternate execution environment enabled application to enable interrupts if the application catches the interrupt and restores the EFI firmware environment prior to calling the UEFI interrupt ISR. After the UEFI ISR context is executed it will return to the alternate execution environment enabled application context.

An alternate execution environment created by a UEFI application must not change the semantics or behavior of the MMU configuration created by the UEFI firmware prior to invoking ExitBootServices(), including the bit layout of the page table entries.

After an OS loader calls ExitBootServices() it should immediately configure the exception vector to point to appropriate code.

2.3.6.4 Detailed Calling Convention

The base calling convention for the AArch64 binding is defined in the document *Procedure Call Standard for the ARM 64-bit Architecture Version A-0.06 (or later)*:

See "Links to UEFI-Related Documents" (http://uefi.org/uefi) under the heading "ARM 64-bit Base Calling Convention"

This binding further constrains the calling convention in these ways:

- The AArch64 execution state must not be modified by the callee.
- All code exits, normal and exceptional, must be from the A64 instruction set.
- Floating point and SIMD instructions may be used.
- Optional vector operations and other instruction set extensions may only be used:
  - After dynamically checking for their existence.
  - Saving and then later restoring any additional execution state context.
  - Additional feature enablement or control, such as power, must be explicitly managed.
- Only little endian operation is supported.
- The stack will maintain 16 byte alignment.
- Structures (or other types larger than 64-bits) must be passed by reference and not by value.
- The EFI AArch64 platform binding defines the platform register (r18) as "do not use". Avoiding use of r18 in firmware makes the code compatible with both a fixed role for r18 defined by the OS platform ABI and the use of r18 by the OS and its applications as a temporary register.

2.3.7 RISC-V Platforms

All functions are called with the C language calling convention. See *Detailed Calling Convention* for more detail. On RISC-V platform, three privileged levels are currently introduced in RISC-V architecture. Beyond the User privilege, Supervisor privilege and Machine privileges cover all aspects of RISC-V system. The privileged instructions are also defined in each privilege level.

Table 2.7: RISC-V Platforms

Level	Encoding	Name	Abbreviation
0	0	User/Application	U
1	1	Supervisor	S
2	10	Reserved	
3	11	Machine	M

A RISC-V platform can contain one or more RISC-V cores and other components such as physical memory, fixed-function accelerators and I/O devices. The term RISC-V core refers to a component which contains an independent instruction fetch unit. A RISC-V core may have multiple RISC-V-compatible hardware threads, or hart. RISC-V UEFI firmware could be executed in either Machine mode or Supervisor mode during the entire POST, according to the hart capability and the platform design. However, RISC-V UEFI firmware has to switch the boot hart to Supervisor mode at either early or late POST if the platform is designed to boot a Supervisor mode OS or OS loader.

The machine mode has the highest privilege and this mode is the only mandatory privilege level for RISC-V platforms; all other privilege levels are optional depending on the platform requirements. Machine mode is the initial privelege mode entered at the power-on reset. This level is used in UEFI for low-level access to a hardware platform.

UEFI firmware implementation may provide the Supervisor Binary Interface (SBI) to allow the Supervisor mode execution environment to invoke privileged functions or access privileged hardware.

The processor is in the following execution mode during boot service:

- Total 32 general-purpose registers x1-x31. Register x0 is hardwired to 0. Each register has its ABI (Application Binary Interface) name. See *Detailed Calling Convention* for more detail.
- The width of the native base integer depends on the RISC-V privileged mode implementation. XLEN is a general term which used to refer the width of base integer in bits.
  - For the Base Integer ISA in 32-bit width, XLEN = 32
  - For the Base Integer ISA in 64-bit width, XLEN = 64
  - For the Base Integer ISA in 128-bit width, XLEN = 128
- The width of processor registers could be determined by placing the immediate 4 in a register then shifting the register left by 31 bits at a time. If zero after one shift, then the machine is RV32. If zero after two shifts, then the machine is RV64, else RV128.
- Processor reset vector is platform specified. In UEFI, it is configured to the platform implementation-defined reset vector. The reset vector address is the first instruction which fetched by RISC-V processor when the power-on reset.
- The mcause value after reset have implementation-specific interpretation, value 0 should be returned on implementations that do not distinguish different reset conditions. Implementations that distinguish different reset conditions should only use 0 to indicate the most complete reset (e.g., hard reset). The causes of reset could be power-on reset, external hard reset, brownout detected, watchdog timer elapse, sleep-mode wakeup, etc., which machine-mode UEFI system firmware has to distinguish.
- The mstatus.xIE indicates the current processor interrupt activation in current privilege mode.
  - mstatus.MIE is set to one while mstatus.SIE and mstatus.UIE are set to zero during early UEFI POST stage.

- The machine mode interrupt is enabled during boot service in UEFI. Two kinds of interrupts are enabled, one is for timer interrupt and another is software interrupt.
- mie.MSIE = 1
- mie.MTIE = 1
- The memory is in physical addressing mode. Page is disabled in RISC-V machine mode during UEFI boot service.
- I/O access is through memory map I/O.
- Only support Machine level Control and Status Registers (CSRs) in UEFI.
- Machine ISA (misa) register contains the information regarding to the capabilities of CPU implementation. The misa.MXL field encodes the native base integer ISA width in machine mode. MXLEN (Machine XLEN) is given by setting of misa.MXL.
  - misa.MXL = 1, MXLEN is 32 bit
  - misa.MXL = 2, MXLEN is 64 bit
  - misa.MXL = 3, MXLEN is 128 bit
- RISC-V processor supports extensive customization and specialization instruction sets. RISC-V variations provide various purposes of processor implementations and the processor capability is reported in the extension bits in misa register. UEFI drivers will need to know the capabilities of processor before executing the specified RISC-V extension instructions. The extensions fields encodes the presence of the standard extensions, with a single bit per letter of the alphabet. (Bit 0 encodes presence of extension “A”, Bit 1 encodes presence of extension “B” and so on. Currently the single letter extension mnemonics are as below,
  - A - Atomic extension
  - B - Tentatively reserved for Bit operations extension
  - C - Compressed extension
  - D - Double-Precision Floating-Point extension
  - E - Reduced Register Set Indicator RV32E (16 registers)
  - F - Single-Precision Floating-Point extension
  - G - Additional standard extensions present
  - H - Hypervisor extension
  - I - RV32I/64I/128I base ISA
  - J - Tentatively reserved for Dynamically Translated Languages extension
  - K - Reserved
  - L - Tentatively reserved for Decimal Floating-Point extension
  - M - Integer Multiplication and Division extension
  - N - User-level interrupts supported
  - O - Reserved
  - P - Tentatively reserved for Packed-SIMD extension
  - Q - Quad-Precision Floating-Point extension
  - S - Supervisor mode implemented
  - T - Tentatively reserved for Transactional Memory extension

  - U - User mode implemented
  - V - Tentatively reserved for Vector extension
  - W - Reserved
  - X - Non-standard extension present
  - Y - Reserved
  - Z - Reserved
  - Zifenci - Instruction-Fetch Fence
  - Zicsr - Control and Status Register Access
- Machine Vendor ID Register
  - The mvendorid is a 32-bit read-only register encoding the manufacture of the part. Value of 0 indicates this field is not implemented or this is a non-commercial implementation.
- Machine Architecture ID Register
  - The marchid is an MXLEN-bit read-only register encoding the base microarchitecture of the hart. The combination of mvendorid and marchid should uniquely identify the type of hart microarchitecture that is implemented.
- Machine Implementation ID Register
  - This provides a unique encoding of the version of processor implementation.

An application written to this specification may alter the processor execution mode, but the UEFI image must ensure firmware boot services and runtime services are executed with the prescribed execution environment.

After an Operating System calls ExitBootServices (), firmware boot services are no longer available and it is illegal to call any boot service. After ExitBootServices, firmware runtime services are still available and may be called with paging enabled and virtual address pointers if SetVirtualAddressMap () has been called describing all virtual address ranges used by the firmware runtime service.

If ACPI is supported:

- ACPI Tables loaded at boot time can be contained in memory of type *EfiACPIReclaimMemory* (recommended) or *EfiACPIMemoryNVS*. ACPI FACS must be contained in memory of type *EfiACPIMemoryNVS*
- The system firmware must not request a virtual mapping for any memory descriptor of type *EfiACPIReclaimMemory* or *EfiACPIMemoryNVS*.
- EFI memory descriptors of type *EfiACPIReclaimMemory* and *EfiACPIMemoryNVS* must be aligned on a 4 KiB boundary and must be a multiple of 4 KiB in size.
- Any UEFI memory descriptor that requests a virtual mapping via the *EFI_MEMORY_DESCRIPTOR* having the *EFI_MEMORY_RUNTIME* bit set must be aligned on a 4 KiB boundary and must be a multiple of 4 KiB in size.
- An ACPI Memory Op-region must inherit cacheability attributes from the UEFI memory map. If the system memory map does not contain cacheability attributes, the ACPI Memory Op-region must inherit its cacheability attributes from the ACPI name space. If no cacheability attributes exist in the system memory map or the ACPI name space, then the region must be assumed to be non-cacheable.
- ACPI tables loaded at runtime must be contained in memory of type *EfiACPIMemoryNVS*.

The cacheability attributes for ACPI tables loaded at runtime should be defined in the UEFI memory map. If no information about the table location exists in the UEFI memory map, cacheability attributes may be obtained from ACPI memory descriptors. If no information about the table location exists in the UEFI memory map or ACPI memory descriptors, the table is assumed to be non-cached.

- In general, UEFI Configuration Tables loaded at boot time (e.g., SMBIOS table) can be contained in memory of type *EfiRuntimeServicesData* (recommended), *EfiBootServicesData*, *EfiACPIReclaimMemory* or *EfiACPIMemoryNVS*. Tables loaded at runtime must be contained in memory of type *EfiRuntimeServicesData* (recommended) or *EfiACPIMemoryNVS*.

Note: *Previous EFI specifications allowed ACPI tables loaded at runtime to be in the* EfiReservedMemoryType *and there was no guidance provided for other EFI Configuration Tables.* EfiReservedMemoryType *is not intended to be used by firmware. The UEFI Specification intends to clarify the situation moving forward. Also, only OSes conforming to the UEFI Specification are guaranteed to handle SMBIOS table in memory of type* EfiBootServicesData.

2.3.7.1 Handoff State

When UEFI firmware hands off control to Supervisor mode OS, RISC-V boot hart must be operated in Supervisor mode, and the memory addressing must be operated in Bare mode which is no memory address translation or protection through the virtual page table entry.

In order to describe the heterogeneous RISC-V cores and harts for the next boot stage after POST, UEFI firmware must build up the information of core and hart hardware capabilities in the firmware data structure if the target bootable image requires this information. (e.g. If the platform supports SMBIOS structure, SMBIOS record type 44 record, see “Link to UEFI Specification-Related Document” on https://uefi.org/uefi under the heading “RISC-V Processor SMBIOS Specification”).

UEFI firmware must exposes RISC-V boot hart ID in the firmware data structure to OS:

- If platform supports SMBIOS, then SMBIOS type 44 record for the boot hart must have “Boot Hart” set to 1 in “RISC-V Processor-specific Data” structure.
- If platform supports Device Tree, the Device Tree must contains a unsigned integer (32bit) property “boot-hartid” under the /chosen node which would indicate the booting hart ID to the supervisor OS.

If the platform supports Device Tree structure to describe the system configurations, the Flattened Device Blob (DTB) must be installed in the EFI Configuration Table (*EFI Configuration Table & Properties Table* for details).

All UEFI images takes two parameters: the UEFI image handle and the pointer to EFI System Table. According to the RISC-V calling convention, EFI_HANDLE is passed through the a0 register and EFI_SYSTEM_TABLE is passed through the a1 register.

- x10: EFI_HANDLE (ABI name: a0)
- x11: EFI_SYSTEM_TABLE * (ABI name: a1)
- x1: Return Address (ABI name: ra)

2.3.7.2 Data Alignment

In the RV32I and RV64I, the datatypes must be aligned at its natural size when stored in memory. The following table describes the datatype and its alignment in RV32I and RV64I in UEFI.

Table 2.8: RV32 datatype alignment

Datatype	Description	Alignment
BOOLEAN	Logical Boolean	1
INTN	Signed value in native width.	4
UINTN	Unsigned value in native width.	4
INT8	1-byte signed value	1
UINT8	1-byte unsigned value	1
INT16	2-byte signed value	2

continues on next page

Table 2.8 – continued from previous page

UINT16	2-byte unsigned value	2
INT32	4-byte signed value	4
UINT32	4-byte unsigned value	4
INT64	8-byte signed value	8
UINT64	8-byte unsigned value	8
CHAR8	1-byte character	1
CHAR16	2-byte character	2
VOID	Undeclared type	4

Table 2.9: RV64 datatype alignment

Datatype	Description	Alignment
BOOLEAN	Logical Boolean	1
INTN	Signed value in native width.	8
UINTN	Unsigned value in native width.	8
INT8	1-byte signed value	1
UINT8	1-byte unsigned value	1
INT16	2-byte signed value	2
UINT16	2-byte unsigned value	2
INT32	4-byte signed value	4
UINT32	4-byte unsigned value	4
INT64	8-byte signed value	8
UINT64	8-byte unsigned value	8
CHAR8	1-byte character	1
CHAR16	2-byte character	2
VOID	Undeclared type	8

2.3.7.3 Detailed Calling Convention

The RISC-V calling convention passes arguments in register when necessary. In RISC-V, total 32 general registers are declared, each register has its corresponding ABI name.

Table 2.10: Register name and ABI name

Register	ABI Name	Description
x0	zero	Hardwired to zero
x1	ra	Return address
x2	sp	Stack pointer
x3	gp	Global pointer
x4	tp	Thread pointer
x5-7	t0-2	Temporaries
x8	s0/fp	Saved register/frame pointer
x9	s1	Saved register
x10-11	a0-1	Function arguments/Return values
x12-17	a2-7	Function arguments
x18-27	s2-11	Saved registers
x28-31	t3-6	Temporaries

In the RISC-V calling convention, up to eight integer registers are used for passing argument, a0-a7. a0-a7 are the ABI names and the corresponding registers are x10-x17. Values are returned from functions in integer registers a0 and a1, those are register x10 and x11. In the standard RISC-V calling convention, the stack grows downward and the stack point is always kept 16-byte aligned. Five integer register t0-t6 are temporary registers that are volatile across calls and must be saved by the caller if later used. Twelve integer registers s0-s11 are preserved across calls and must be saved by the callee if used.

In view of the following statement:

"In the standard ABI, procedures should not modify the integer registers tp and gp, because signal handlers may rely upon their values"

mentioned in the RISC-V EFL psABI Specification, and the RISC-V calling convention that gp and tp registers are not assigned a specific owner to save and restore their values (see links below), UEFI firmware must neither trust the values of tp and gp nor make an assumption of owning the write access to these register in any circumstances. (Such as in EFI Boot service, EFI Runtime service, EFI Management Mode service and any UEFI firmware interfaces which may invoked by the EFI drivers, OS or external firmware payload.)

Preserve the values in gp or tp register if UEFI firmware needs to change them, and never touch them after ExitBootServices(). Whether and how to preserve gp and tp in the UEFI firmware environment is implementation-specific.

See Links to UEFI Specification-Related Documents (https://uefi.org/uefi) under the heading "RISC-V EFL psABI Specification", and the RISC-V assembly programmer's handbook section in the RISC-V Unprivileged ISA specification.

2.4 Protocols

The protocols that a device handle supports are discovered through the *EFI_BOOT_SERVICES.HandleProtocol()* Boot Service or *EFI_BOOT_SERVICES.OpenProtocol()* Boot Service. Each protocol has a specification that includes the following:

- The protocol's globally unique ID (GUID)
- The Protocol Interface structure
- The Protocol Services

Unless otherwise specified a protocol's interface structure is not allocated from runtime memory and the protocol member functions should not be called at runtime. If not explicitly specified a protocol member function can be called at a TPL level of less than or equal to TPL_NOTIFY (*Event, Timer, and Task Priority Services*). Unless otherwise specified a protocol's member function is not reentrant or MP safe.

Any status codes defined by the protocol member function definition are required to be implemented, Additional error codes may be returned, but they will not be tested by standard compliance tests, and any software that uses the procedure cannot depend on any of the extended error codes that an implementation may provide.

To determine if the handle supports any given protocol, the protocol's GUID is passed to HandleProtocol() or OpenProtocol() . If the device supports the requested protocol, a pointer to the defined Protocol Interface structure is returned. The Protocol Interface structure links the caller to the protocol-specific services to use for this device.

The Figue below shows the construction of a protocol. The UEFI driver contains functions specific to one or more protocol implementations, and registers them with the Boot Service, see *EFI_BOOT_SERVICES.InstallProtocolInterface()*. The firmware returns the Protocol Interface for the protocol that is then used to invoke the protocol specific services. The UEFI driver keeps private, device-specific context with protocol interfaces.

The following C code fragment illustrates the use of protocols:

```c
// There is a global "EffectsDevice" structure. This
// structure contains information  to the device.

// Connect to the ILLUSTRATION_PROTOCOL on the EffectsDevice,
```

(continues on next page)

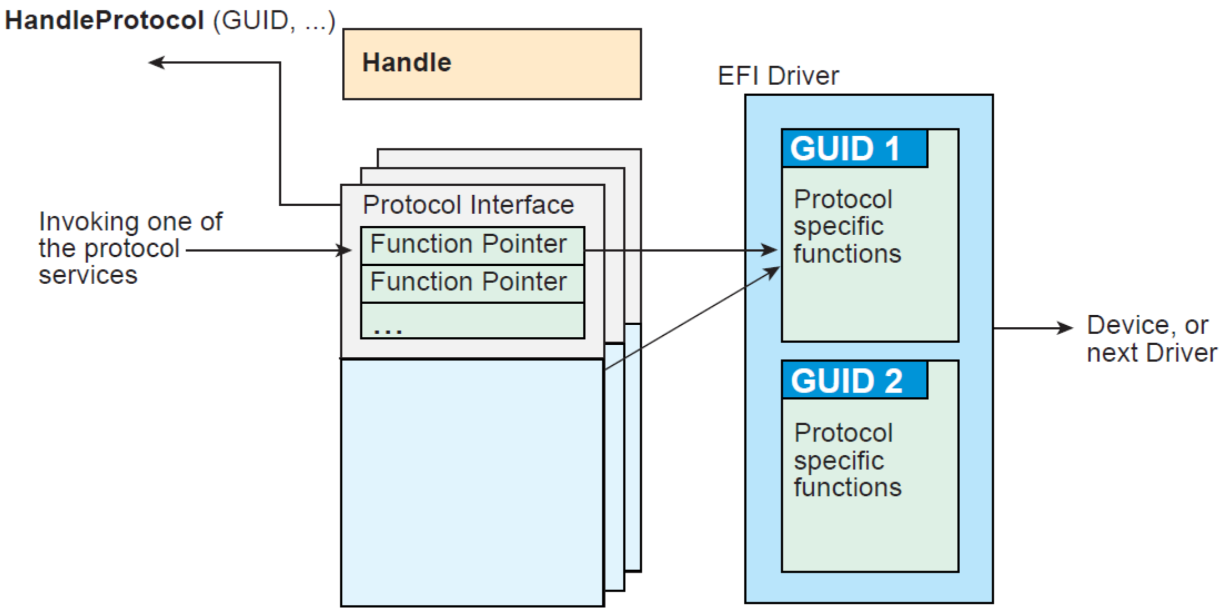

Fig. 2.4: Construction of a Protocol

(continued from previous page)

```
// by calling HandleProtocol with the device's EFI device handle
// and the ILLUSTRATION_PROTOCOL GUID.

EffectsDevice.Handle = DeviceHandle;
Status = HandleProtocol (
   EffectsDevice.EFIHandle,
   &IllustrationProtocolGuid,
   &EffectsDevice.IllustrationProtocol
   );

// Use the EffectsDevice illustration protocol's "MakeEffects"
// service to make flashy and noisy effects.

      Status = EffectsDevice.IllustrationProtocol->MakeEffects (
      EffectsDevice.IllustrationProtocol,
      TheFlashyAndNoisyEffect
      );
```

The Table below, *UEFI Protocols* , lists the UEFI protocols defined by this specification.

Table 2.11: UEFI Protocols

Protocol	**Description**
EFI Loaded Image Protocol	Provides information on the image.
EFI Loaded Image Device Path Protocol	Specifies the device path that was used when a PE/COFF image was loaded through the EFI Boot Service LoadImage().
EFI Device Path Protocol	Provides the location of the device.

continues on next page

Table 2.11 – continued from previous page

EFI Driver Binding Protocol	Provides services to determine if an UEFI driver supports a given controller, and services to start and stop a given controller.
EFI_DRIVER_FAMILY_OVERRIDE_PROTOCOL	Provides a the Driver Family Override mechanism for selecting the best driver for a given controller.
EFI Platform Driver Override Protocol	Provide a platform specific override mechanism for the selection of the best driver for a given controller.
EFI_BUS_SPECIFIC_DRIVER_OVERRIDE_PROTOCOL	Provides a bus specific override mechanism for the selection of the best driver for a given controller.
EFI_DRIVER_DIAGNOSTICS2_PROTOCOL	Provides diagnostics services for the controllers that UEFI drivers are managing.
EFI_COMPONENT_NAME2_PROTOCOL	Provides human readable names for UEFI Drivers and the controllers that the drivers are managing.
EFI_SIMPLE_TEXT_INPUT_PROTOCOL	Protocol interfaces for devices that support simple console style text input.
EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL	Protocol interfaces for devices that support console style text displaying.
EFI_SIMPLE_POINTER_PROTOCOL	Protocol interfaces for devices such as mice and trackballs.
EFI_SERIAL_IO_PROTOCOL	Protocol interfaces for devices that support serial character transfer.
EFI_LOAD_FILE_PROTOCOL	Protocol interface for reading a file from an arbitrary device.
EFI_LOAD_FILE2_PROTOCOL	Protocol interface for reading a non-boot option file from an arbitrary device
EFI_SIMPLE_FILE_SYSTEM_PROTOCOL	Protocol interfaces for opening disk volume containing a UEFI file system.
EFI_FILE_PROTOCOL	Provides access to supported file systems.
EFI_DISK_IO_PROTOCOL	A protocol interface that layers onto any BLOCK_IO or BLOCK_IO_EX interface.
EFI_BLOCK_IO_PROTOCOL	Protocol interfaces for devices that support block I/O style accesses.
EFI_BLOCK_IO2_PROTOCOL	Protocol interfaces for devices that support block I/O style accesses. This interface is capable of non-blocking transactions.
EFI_UNICODE_COLLATION_PROTOCOL	Protocol interfaces for string comparison operations.
EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL	Protocol interfaces to abstract memory, I/O, PCI configuration, and DMA accesses to a PCI root bridge controller.
EFI PCI I/O Protocol	Protocol interfaces to abstract memory, I/O, PCI configuration, and DMA accesses to a PCI controller on a PCI bus.
EFI_USB_IO_PROTOCOL	Protocol interfaces to abstract access to a USB controller.
EFI_SIMPLE_NETWORK_PROTOCOL	Provides interface for devices that support packet based transfers.
EFI_PXE_BASE_CODE_PROTOCOL	Protocol interfaces for devices that support network booting.

continues on next page

Table 2.11 – continued from previous page

EFI_BIS_PROTOCOL	Protocol interfaces to validate boot images before they are loaded and invoked.
EFI_DEBUG_SUPPORT_PROTOCOL	Protocol interfaces to save and restore processor context and hook processor exceptions.
EFI_DEBUGPORT_PROTOCOL	Protocol interface that abstracts a byte stream connection between a debug host and a debug target system.
EFI_DECOMPRESS_PROTOCOL	Protocol interfaces to decompress an image that was compressed using the EFI Compression Algorithm.
EFI_EBC_PROTOCOL	Protocols interfaces required to support an EFI Byte Code interpreter.
EFI_GRAPHICS_OUTPUT_PROTOCOL	Protocol interfaces for devices that support graphical output.
EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL	Protocol interfaces that allow NVM Express commands to be issued to an NVM Express controller.
EFI_EXT_SCSI_PASS_THRU_PROTOCOL	Protocol interfaces for a SCSI channel that allows SCSI Request Packets to be sent to SCSI devices.
EFI_USB2_HC_PROTOCOL	Protocol interfaces to abstract access to a USB Host Controller.
EFI_AUTHENTICATION_INFO_PROTOCOL	Provides access for generic authentication information associated with specific device paths
EFI_DEVICE_PATH_UTILITIES_PROTOCOL	Aids in creating and manipulating device paths.
EFI_DEVICE_PATH_TO_TEXT_PROTOCOL	Converts device nodes and paths to text.
EFI_DEVICE_PATH_FROM_TEXT_PROTOCOL	Converts text to device paths and device nodes.
EFI_EDID_DISCOVERED_PROTOCOL	Contains the EDID information retrieved from a video output device.
EFI_EDID_ACTIVE_PROTOCOL	Contains the EDID information for an active video output device.
EFI_EDID_OVERRIDE_PROTOCOL	Produced by the platform to allow the platform to provide EDID information to the producer of the Graphics Output protocol
EFI iSCSI Initiator Name Protocol	Sets and obtains the iSCSI Initiator Name.
EFI_TAPE_IO_PROTOCOL	Provides services to control and access a tape drive.
EFI Managed Network Protocol	Used to locate communication devices that are supported by an MNP driver and create and destroy instances of the MNP child protocol driver that can use the underlying communications devices.
EFI_ARP_SERVICE_BINDING_PROTOCOL	Used to locate communications devices that are supported by an ARP driver and to create and destroy instances of the ARP child protocol driver.
EFI_ARP_PROTOCOL	Used to resolve local network protocol addresses into network hardware addresses.
EFI_DHCP4_SERVICE_BINDING_PROTOCOL	Used to locate communication devices that are supported by an EFI DHCPv4 Protocol driver and to create and destroy EFI DHCPv4 Protocol child driver instances that can use the underlying communications devices.

continues on next page

Table 2.11 – continued from previous page

EFI_DHCP4_PROTOCOL	Used to collect configuration information for the EFI IPv4 Protocol drivers and to provide DHCPv4 server and PXE boot server discovery services.
EFI_TCP4_SERVICE_BINDING_PROTOCOL	Used to locate EFI TCPv4Protocol drivers to create and destroy child of the driver to communicate with other host using TCP protocol.
EFI_TCP4_PROTOCOL	Provides services to send and receive data stream.
EFI_IP4_SERVICE_BINDING_PROTOCOL	Used to locate communication devices that are supported by an EFI IPv4 Protocol Driver and to create and destroy instances of the EFI IPv4 Protocol child protocol driver that can use the underlying communication device.
EFI_IP4_PROTOCOL	Provides basic network IPv4 packet I/O services.
EFI_IP4_CONFIG2_PROTOCOL	The EFI IPv4 Config Protocol driver performs platform- and policy-dependent configuration of the EFI IPv4 Protocol driver.
EFI_IP4_CONFIG2_PROTOCOL	The EFI IPv4 Configuration II Protocol driver performs platform- and policy-dependent configuration of the EFI IPv4 Protocol driver.
EFI_UDP4_SERVICE_BINDING_PROTOCOL	Used to locate communication devices that are supported by an EFI UDPv4 Protocol driver and to create and destroy instances of the EFI UDPv4 Protocol child protocol driver that can use the underlying communication device.
EFI_UDP4_PROTOCOL	Provides simple packet-oriented services to transmit and receive UDP packets.
EFI_MTFTP4_SERVICE_BINDING_PROTOCOL	Used to locate communication devices that are supported by an EFI MTFTPv4 Protocol driver and to create and destroy instances of the EFI MTFTPv4 Protocol child protocol driver that can use the underlying communication device.
EFI_MTFTP4_PROTOCOL	Provides basic services for client-side unicast or multicast TFTP operations.
EFI_HASH_PROTOCOL	Allows creating a hash of an arbitrary message digest using one or more hash algorithms.
EFI_HASH_SERVICE_BINDING_PROTOCOL	Used to locate hashing services support provided by a driver and create and destroy instances of the EFI Hash Protocol so that a multiple drivers can use the underlying hashing services.
EFI_SD_MMC_PASS_THRU_PROTOCOL	Protocol interface that allows SD/eMMC commands to be sent to an SD/eMMC controller.

2.5 UEFI Driver Model

The UEFI Driver Model is intended to simplify the design and implementation of device drivers, and produce small executable image sizes. As a result, some complexity has been moved into bus drivers and in a larger part into common firmware services.

A device driver is required to produce a Driver Binding Protocol on the same image handle on which the driver was loaded. It then waits for the system firmware to connect the driver to a controller. When that occurs, the device driver is responsible for producing a protocol on the controller's device handle that abstracts the I/O operations that the controller supports. A bus driver performs these exact same tasks. In addition, a bus driver is also responsible for discovering any child controllers on the bus, and creating a device handle for each child controller found.

One assumption is that the architecture of a system can be viewed as a set of one or more processors connected to one or more core chipsets. The core chipsets are responsible for producing one or more I/O buses. The UEFI Driver Model does not attempt to describe the processors or the core chipsets. Instead, the UEFI Driver Model describes the set of I/O buses produced by the core chipsets, and any children of these I/O buses. These children can either be devices or additional I/O buses. This can be viewed as a tree of buses and devices with the core chipsets at the root of that tree.

The leaf nodes in this tree structure are peripherals that perform some type of I/O. This could include keyboards, displays, disks, network, etc. The nonleaf nodes are the buses that move data between devices and buses, or between different bus types. *Desktop System* shows a sample desktop system with four buses and six devices.

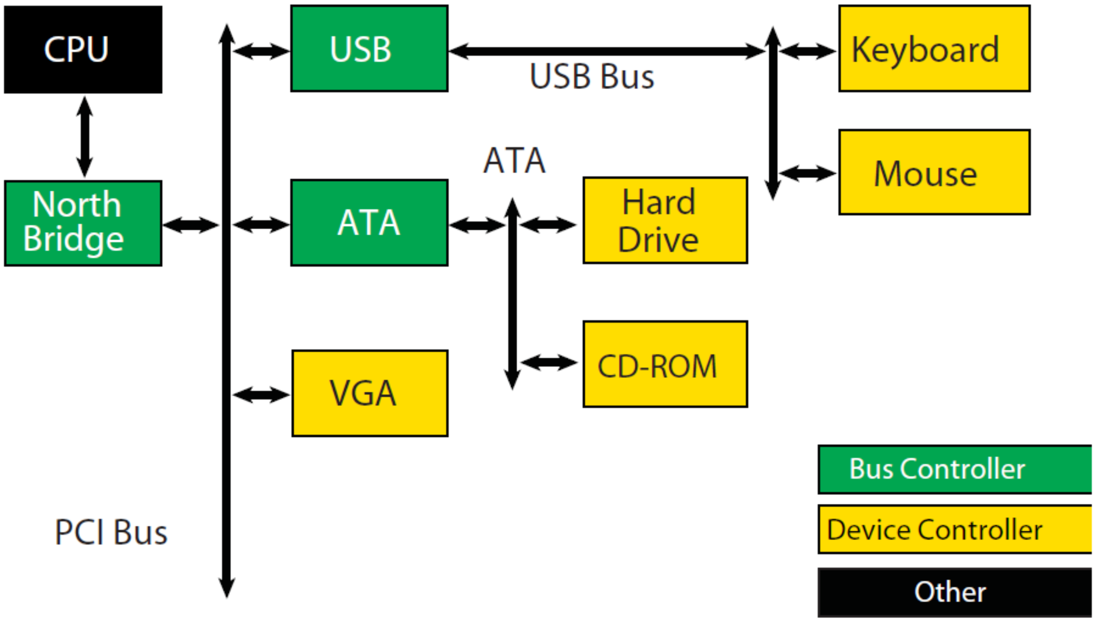

Fig. 2.5: Desktop System

Server System is an example of a more complex server system. The idea is to make the UEFI Driver Model simple and extensible so more complex systems like the one below can be described and managed in the preboot environment. This system contains six buses and eight devices.

The combination of firmware services, bus drivers, and device drivers in any given platform is likely to be produced by a wide variety of vendors including OEMs, IBVs, and IHVs. These different components from different vendors are required to work together to produce a protocol for an I/O device than can be used to boot a UEFI compliant operating system. As a result, the UEFI *Driver Model* is described in great detail in order to increase the interoperability of these components

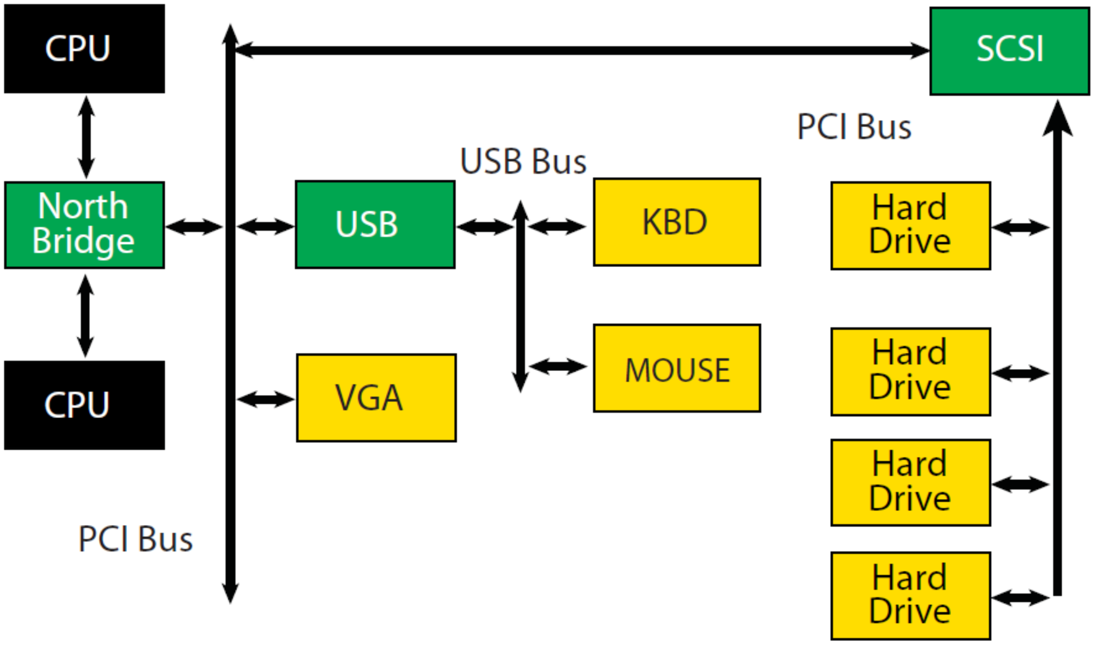

Fig. 2.6: Server System

This remainder of this section is a brief overview of the UEFI *Driver Model*. It describes the legacy option ROM issues that the UEFI Driver Model is designed to address, the entry point of a driver, host bus controllers, properties of device drivers, properties of bus drivers, and how the UEFI *Driver Model* can accommodate hot-plug events.

2.5.1 Legacy Option ROM Issues

Legacy option ROMs have a number of constraints and limitations that restrict innovation on the part of platform designers and adapter vendors. At the time of writing, both ISA and PCI adapters use legacy option ROMs. For the purposes of this discussion, only PCI option ROMs will be considered; legacy ISA option ROMs are not supported as part of the *UEFI Specification* .

The following is a list of the major constraints and limitations of legacy option ROMs. For each issue, the design considerations that went into the design of the UEFI *Driver Model* are also listed. Thus, the design of the UEFI *Driver Model* directly addresses the requirements for a solution to overcome the limitations implicit to PC-AT-style legacy option ROMs.

2.5.1.1 32-bit/16-Bit Real Mode Binaries

Legacy option ROMs typically contain 16-bit real mode code for an IA-32 processor. This means that the legacy option ROM on a PCI card cannot be used in platforms that do not support the execution of IA-32 real mode binaries. Also, 16-bit real mode only allows the driver to access directly the lower 1 MiB of system memory. It is possible for the driver to switch the processor into modes other than real mode in order to access resources above 1 MiB, but this requires a lot of additional code, and causes interoperability issues with other option ROMs and the system BIOS. Also, option ROMs that switch the processor into to alternate execution modes are not compatible with Itanium Processors.

UEFI *Driver Model* design considerations:

- Drivers need flat memory mode with full access to system components.

- Drivers need to be written in C so they are portable between processor architectures.
- Drivers may be compiled into a virtual machine executable, allowing a single binary driver to work on machines using different processor architectures.

2.5.1.2 Fixed Resources for Working with Option ROMs

Since legacy option ROMs can only directly address the lower 1 MiB of system memory, this means that the code from the legacy option ROM must exist below 1 MiB. In a PC-AT platform, memory from 0x00000-0x9FFFF is system memory. Memory from 0xA0000-0xBFFFF is VGA memory, and memory from 0xF0000-0xFFFFF is reserved for the system BIOS. Also, since system BIOS has become more complex over the years, many platforms also use 0xE0000-0xEFFFF for system BIOS. This leaves 128 KiB of memory from 0xC0000-0xDFFFF for legacy option ROMs. This limits how many legacy option ROMs can be run during BIOS POST.

Also, it is not easy for legacy option ROMs to allocate system memory. Their choices are to allocate memory from Extended BIOS Data Area (EBDA), allocate memory through a Post Memory Manager (PMM), or search for free memory based on a heuristic. Of these, only EBDA is standard, and the others are not used consistently between adapters, or between BIOS vendors, which adds complexity and the potential for conflicts.

UEFI *Driver Model* design considerations:

- Drivers need flat memory mode with full access to system components.
- Drivers need to be capable of being relocated so that they can be loaded anywhere in memory (PE/COFF Images)
- Drivers should allocate memory through the boot services. These are well-specified interfaces, and can be guaranteed to function as expected across a wide variety of platform implementations.

2.5.1.3 Matching Option ROMs to their Devices

It is not clear which controller may be managed by a particular legacy option ROM. Some legacy option ROMs search the entire system for controllers to manage. This can be a lengthy process depending on the size and complexity of the platform. Also, due to limitation in BIOS design, all the legacy option ROMs must be executed, and they must scan for all the peripheral devices before an operating system can be booted. This can also be a lengthy process, especially if SCSI buses must be scanned for SCSI devices. This means that legacy option ROMs are making policy decision about how the platform is being initialized, and which controllers are managed by which legacy option ROMs. This makes it very difficult for a system designer to predict how legacy option ROMs will interact with each other. This can also cause issues with on-board controllers, because a legacy option ROM may incorrectly choose to manage the on-board controller.

UEFI *Driver Model* design considerations:

- Driver to controller matching must be deterministic
- Give OEMs more control through Platform Driver Override Protocol and Driver Configuration Protocol
- It must be possible to start only the drivers and controllers required to boot an operating system.

2.5.1.4 Ties to PC-AT System Design

Legacy option ROMs assume a PC-AT-like system architecture. Many of them include code that directly touches hardware registers. This can make them incompatible on legacy-free and headless platforms. Legacy option ROMs may also contain setup programs that assume a PC-AT-like system architecture to interact with a keyboard or video display. This makes the setup application incompatible on legacy-free and headless platforms.

UEFI *Driver Model* design considerations:

- Drivers should use well-defined protocols to interact with system hardware, system input devices, and systemoutput devices.

2.5.1.5 Ambiguities in Specification and WorkaroundsBorn of Experience

Many legacy option ROMs and BIOS code contain workarounds because of incompatibilities between legacy option ROMs and system BIOS. These incompatibilities exist in part because there are no clear specifications on how to write a legacy option ROM or write a system BIOS.

Also, interrupt chaining and boot device selection is very complex in legacy option ROMs. It is not always clear which device will be the boot device for the OS.

UEFI *Driver Model* design considerations:

- Drivers and firmware are written to follow this specification. Since both components have a clearly defined specification, compliance tests can be developed to prove that drivers and system firmware are compliant. This should eliminate the need to build workarounds into either drivers or system firmware (other than those that might be required to address specific hardware issues).
- Give OEMs more control through Platform Driver Override Protocol and Driver Configuration Protocol and other OEM value-add components to manage the boot device selection process.

2.5.2 Driver Initialization

The file for a driver image must be loaded from some type of media. This could include ROM, FLASH, hard drives, floppy drives, CD-ROM, or even a network connection. Once a driver image has been found, it can be loaded into system memory with the boot service *EFI_BOOT_SERVICES.LoadImage()* . LoadImage() loads a PE/COFF formatted image into system memory. A handle is created for the driver, and a Loaded Image Protocol instance is placed on that handle. A handle that contains a Loaded Image Protocol instance is called an *Image Handle*. At this point, the driver has not been started. It is just sitting in memory waiting to be started. The figure below shows the state of an image handle for a driver after LoadImage() has been called.

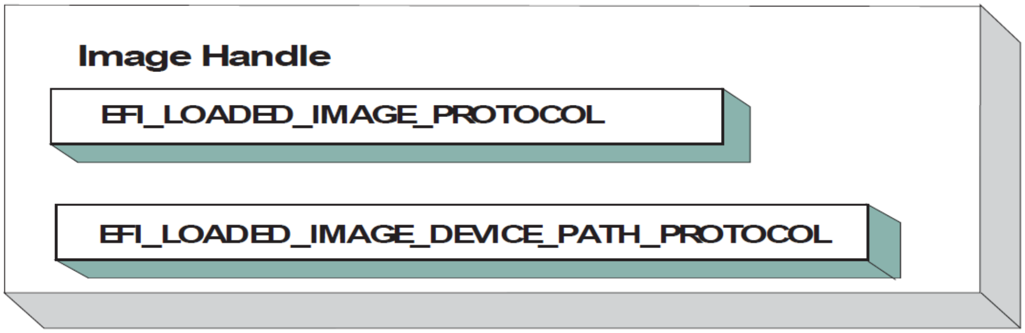

Fig. 2.7: **Image Handle**

After a driver has been loaded with the boot service LoadImage(), it must be started with the boot service *EFI_BOOT_SERVICES.StartImage()*. This is true of all types of UEFI Applications and UEFI Drivers that can be loaded and started on an UEFI-compliant system. The entry point for a driver that follows the UEFI *Driver Model* must follow some strict rules. First, it is not allowed to touch any hardware. Instead, the driver is only allowed to install protocol instances onto its own *Image Handle*. A driver that follows the UEFI *Driver Model* is *required* to install an instance of the Driver Binding Protocol onto its own *Image Handle* . It may optionally install the Driver Configuration Protocol, the Driver Diagnostics Protocol, or the Component Name Protocol. In addition, if a driver wishes to be unloadable it may optionally update the Loaded Image Protocol (*EFI Loaded Image Protocol*) to provide its own Unload() *EFI_LOADED_IMAGE_PROTOCOL.Unload()* function. Finally, if a driver needs to perform any special operations when the boot service *EFI_BOOT_SERVICES.ExitBootServices()* is called, it may optionally create an event with a notification function that is triggered when the boot service ExitBootServices() is called. An *Image Handle* that contains a Driver Binding Protocol instance is known as a *Driver Image Handle* . *Driver Image Handle* shows a possible configuration for the Image Handle from Fig. 2.7 after the boot service StartImage() has been called.

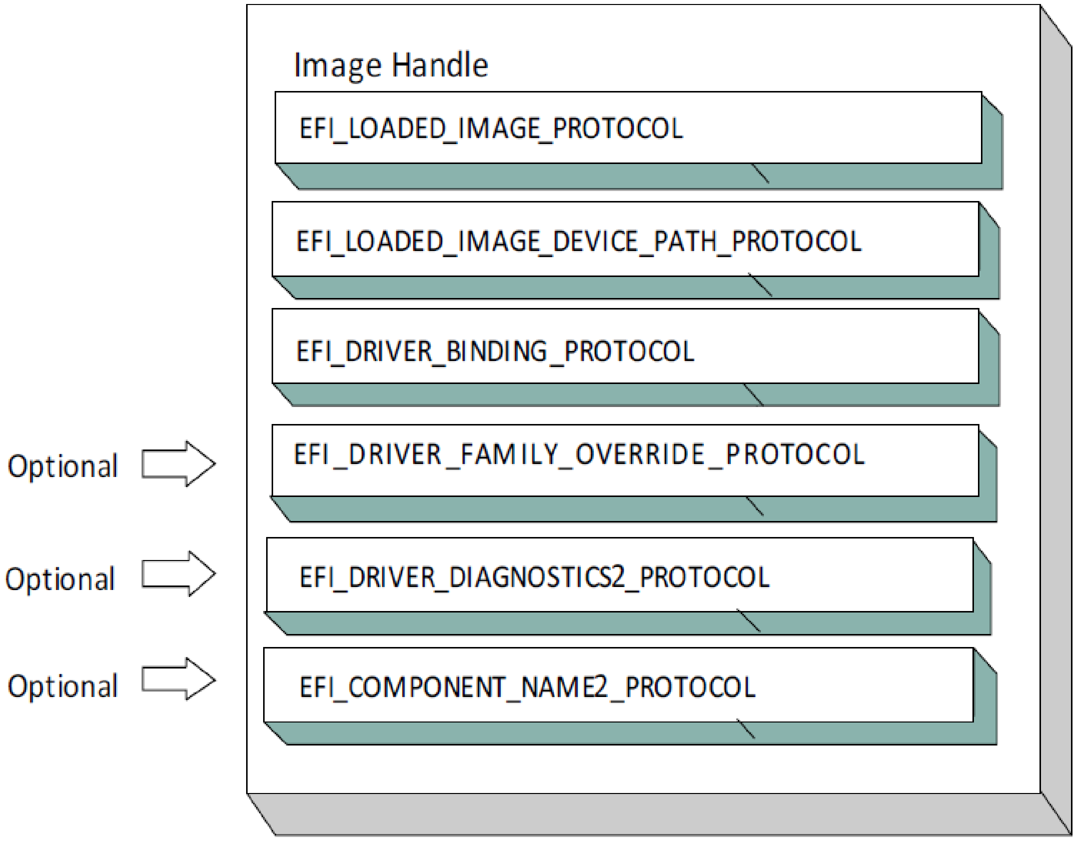

Fig. 2.8: **Driver Image Handle**

2.5.3 Host Bus Controllers

Drivers are not allowed to touch any hardware in the driver's entry point. As a result, drivers will be loaded and started, but they will all be waiting to be told to manage one or more controllers in the system. A platform component, like the Boot Manager, is responsible for managing the connection of drivers to controllers. However, before even the first connection can be made, there has to be some initial collection of controllers for the drivers to manage. This initial collection of controllers is known as the Host Bus Controllers. The I/O abstractions that the *Host Bus Controllers* provide are produced by firmware components that are outside the scope of the UEFI Driver Model . The device handles for the Host Bus Controllers and the I/O abstraction for each one must be produced by the core firmware on the platform, or a driver that may not follow the UEFI Driver Model. See the PCI Root Bridge I/O Protocol Specification for an example of an I/O abstraction for PCI buses.

A platform can be viewed as a set of processors and a set of core chipset components that may produce one or more host buses. The following figure shows a platform with n processors (CPUs), and a set of core chipset components that produce m host bridges.

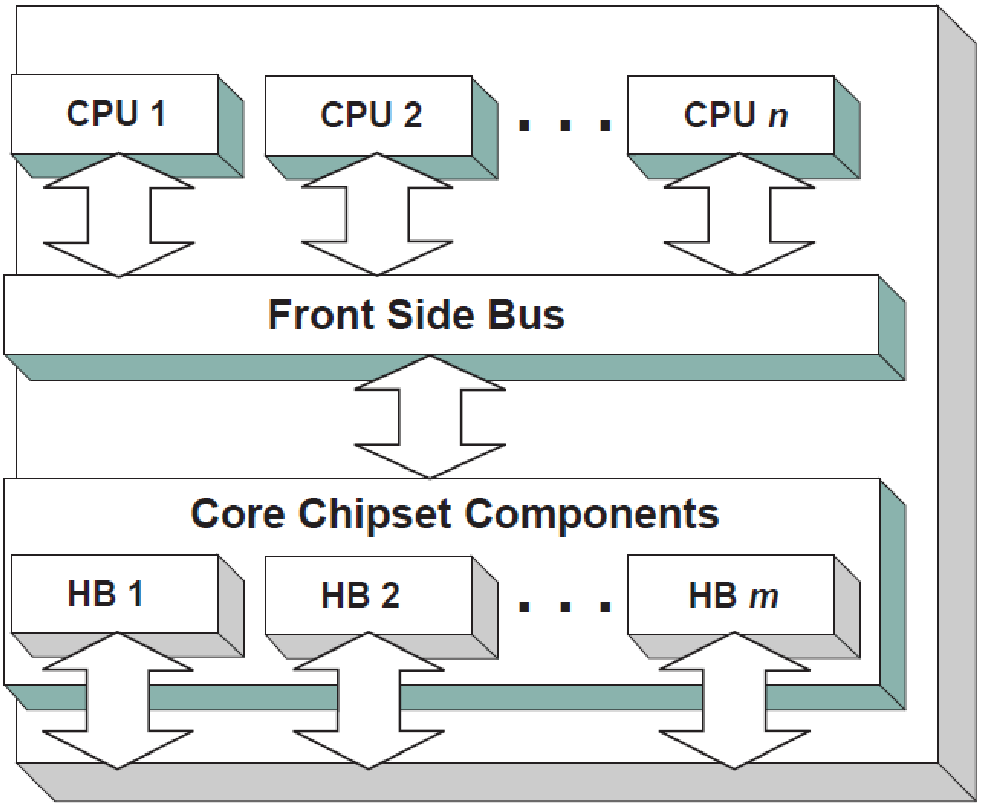

Fig. 2.9: **Host Bus Controllers**

Each host bridge is represented in UEFI as a device handle that contains a Device Path Protocol instance, and a protocol instance that abstracts the I/O operations that the host bus can perform. For example, a PCI Host Bus Controller supports one or more PCI Root Bridges that are abstracted by the PCI Root Bridge I/O Protocol. The following figure shows an example device handle for a PCI Root Bridge.

A PCI Bus Driver could connect to this PCI Root Bridge, and create child handles for each of the PCI devices in the system. PCI Device Drivers should then be connected to these child handles, and produce I/O abstractions that may be used to boot a UEFI compliant OS. The following section describes the different types of drivers that can be implemented within the UEFI *Driver Model*. The UEFI *Driver Model* is very flexible, so all the possible types of drivers will not be discussed here. Instead, the major types will be covered that can be used as a starting point for

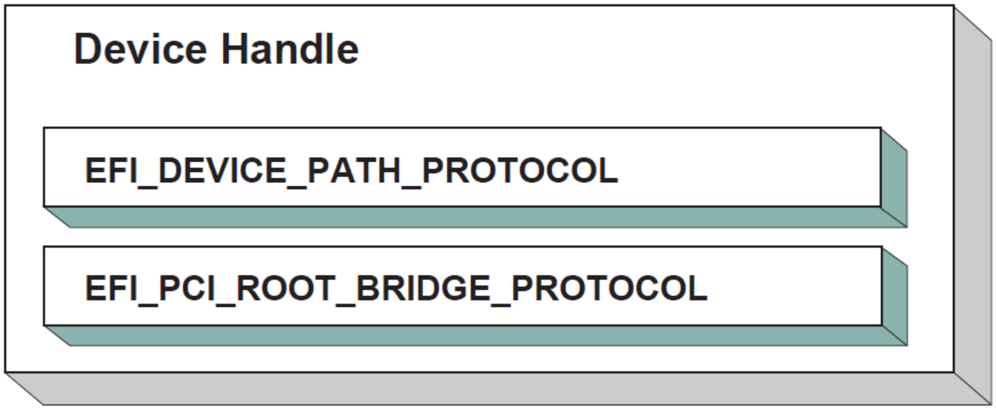

Fig. 2.10: **PCI Root Bridge Device Handle**

designing and implementing additional driver types.

2.5.4 Device Drivers

A device driver is not allowed to create any new device handles. Instead, it installs additional protocol interfaces on an existing device handle. The most common type of device driver will attach an I/O abstraction to a device handle that was created by a bus driver. This I/O abstraction may be used to boot a UEFI compliant OS. Some example I/O abstractions would include Simple Text Output, Simple Input, Block I/O, and Simple Network Protocol. Fig. 2.11 shows a device handle before and after a device driver is connected to it. In this example, the device handle is a child of the XYZ Bus, so it contains an XYZ I/O Protocol for the I/O services that the XYZ bus supports. It also contains a Device Path Protocol that was placed there by the XYZ Bus Driver. The Device Path Protocol is not required for all device handles. It is only required for device handles that represent physical devices in the system. Handles for virtual devices will not contain a Device Path Protocol.

The device driver that connects to the device handle in the above Figure must have installed a Driver Binding Protocol on its own image handle. The Driver Binding Protocol contains three functions called Supported() (*EFI_DRIVER_BINDING_PROTOCOL.Supported()*); Start() (*EFI_DRIVER_BINDING_PROTOCOL.Start()*), and Stop() (*EFI_DRIVER_BINDING_PROTOCOL.Stop()*). The Supported() function tests to see if the driver supports a given controller. In this example, the driver will check to see if the device handle supports the Device Path Protocol and the XYZ I/O Protocol. If a driver's Supported() function passes, then the driver can be connected to the controller by calling the driver's Start() function. The Start() function is what actually adds the additional I/O protocols to a device handle. In this example, the Block I/O Protocol is being installed. To provide symmetry, the Driver Binding Protocol also has a Stop()function that forces the driver to stop managing a device handle. This will cause the device driver to uninstall any protocol interfaces that were installed in Start().

The Supported() , Start() , and Stop() functions of the EFI Driver Binding Protocol are required to make use of the boot service *EFI_BOOT_SERVICES.OpenProtocol()* to get a protocol interface and the boot service *EFI_BOOT_SERVICES.CloseProtocol()* to release a protocol interface. OpenProtocol() and CloseProtocol() update the handle database maintained by the system firmware to track which drivers are consuming protocol interfaces. The information in the handle database can be used to retrieve information about both drivers and controllers. The new boot service *EFI_BOOT_SERVICES.OpenProtocolInformation()* can be used to get the list of components that are currently consuming a specific protocol interface.

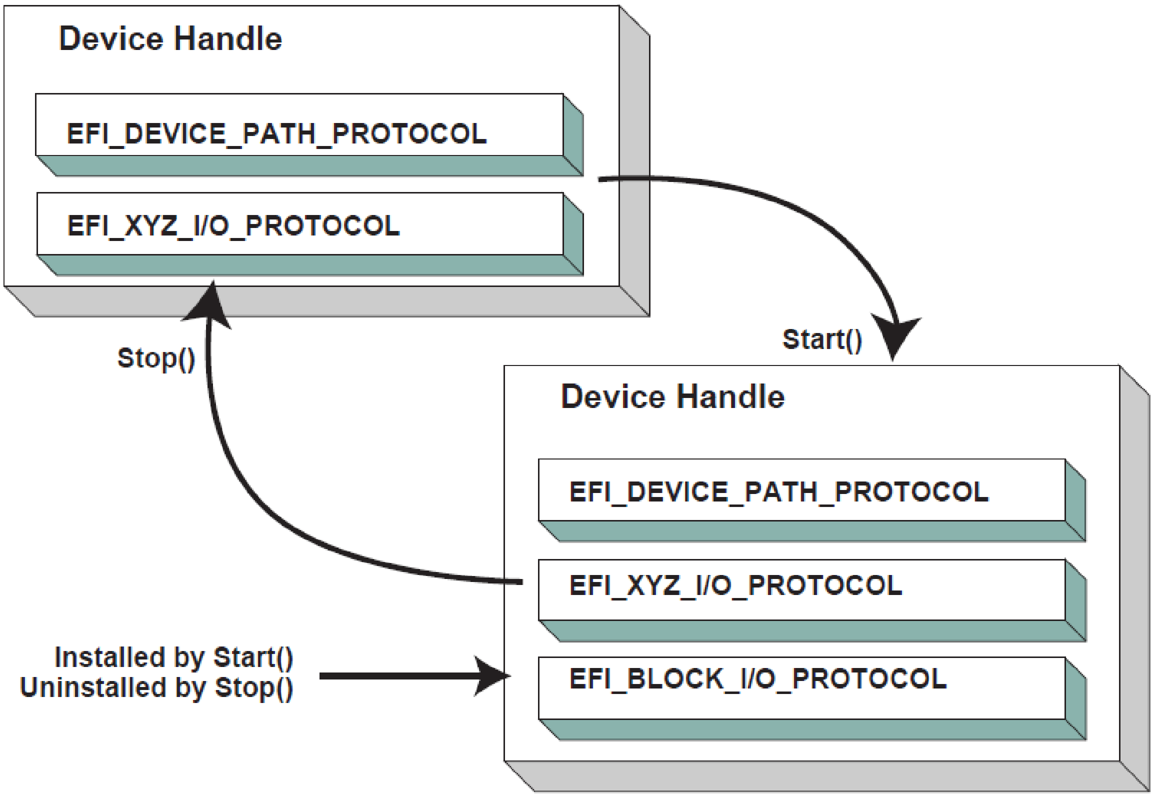

Fig. 2.11: **Connecting Device Drivers**

2.5.5 Bus Drivers

Bus drivers and device drivers are virtually identical from the UEFI Driver Model 's point of view. The only difference is that a bus driver creates new device handles for the child controllers that the bus driver discovers on its bus. As a result, bus drivers are slightly more complex than device drivers, but this in turn simplifies the design and implementation of device drivers. There are two major types of bus drivers. The first creates handles for all child controllers on the first call to Start() . The other type allows the handles for the child controllers to be created across multiple calls to Start() . This second type of bus driver is very useful in supporting a rapid boot capability. It allows a few child handles or even one child handle to be created. On buses that take a long time to enumerate all of their children (e.g. SCSI), this can lead to a very large timesaving in booting a platform. *Connecting Bus Drivers* shows the tree st ructure of a bus controller before and after Start() is called. The dashed line coming into the bus controller node represents a link to the bus controller's parent controller. If the bus controller is a Host Bus Controller , then it will not have a parent controller. Nodes A, B, C ,D, and E represent the child controllers of the bus controller.

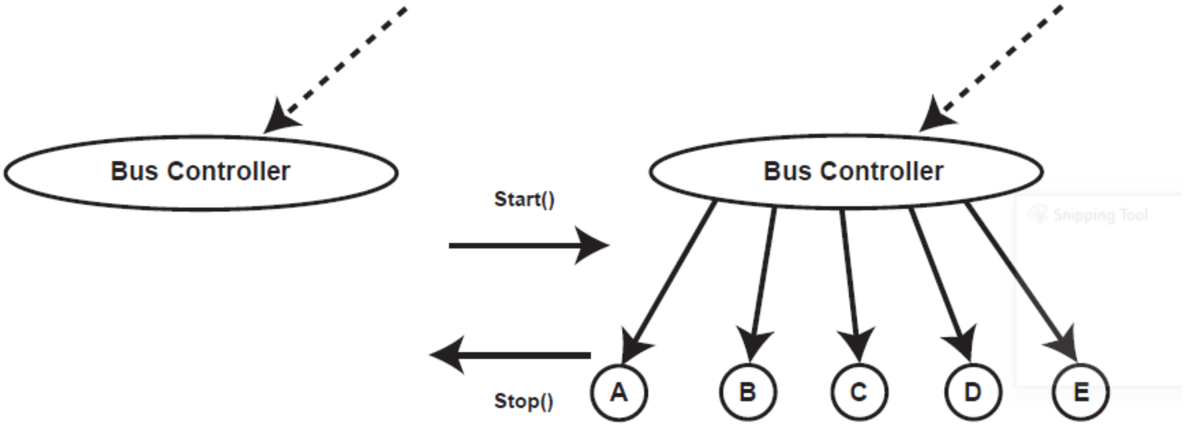

Fig. 2.12: Connecting Bus Drivers

A bus driver that supports creating one child on each call to Start() might choose to create child C first, and then child E, and then the remaining children A, B, and D. The Supported() , Start() , and Stop() functions of the Driver Binding Protocol are flexible enough to allow this type of behavior.

A bus driver must install protocol interfaces onto every child handle that is creates. At a minimum, it must install a protocol interface that provides an I/O abstraction of the bus's services to the child controllers. If the bus driver creates a child handle that represents a physical device, then the bus driver must also install a Device Path Protocol instance onto the child handle. A bus driver may optionally install a Bus Specific Driver Override Protocol onto each child handle. This protocol is used when drivers are connected to the child controllers. The boot service *EFI_BOOT_SERVICES.ConnectController()* uses architecturally defined precedence rules to choose the best set of drivers for a given controller. The Bus Specific Driver Override Protocol has higher precedence than a general driver search algorithm, and lower precedence than platform overrides. An example of a bus specific driver selection occurs with PCI. A PCI Bus Driver gives a driver stored in a PCI controller's option ROM a higher precedence than drivers stored elsewhere in the platform. *Child Device Handle with a Bus Specific Override* shows an example child device handle that was created by the XYZ Bus Driver that supports a bus specific driver override mechanism.

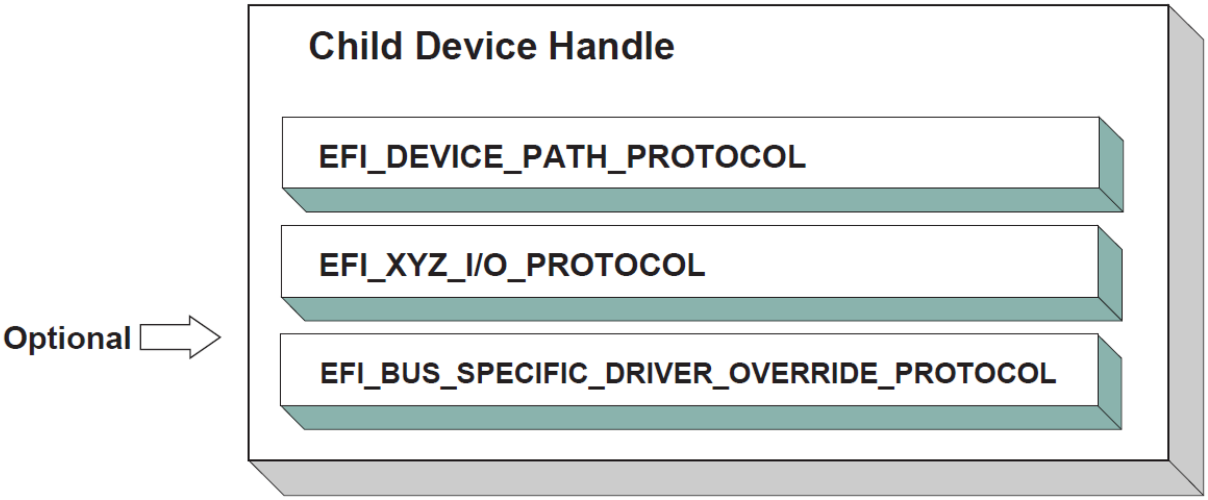

Fig. 2.13: Child Device Handle with a Bus Specific Override

2.5.6 Platform Components

Under the UEFI Driver Model , the act of connecting and disconnecting drivers from controllers in a platform is under the platform firmware's control. This will typically be implemented as part of the UEFI Boot Manager, but other implementations are possible. The boot services *EFI_BOOT_SERVICES.ConnectController()* and *EFI_BOOT_SERVICES.DisconnectController()* can be used by the platform firmware to determine which controllers get started and which ones do not. If the platform wishes to perform system diagnostics or install an operating system, then it may choose to connect drivers to all possible boot devices. If a platform wishes to boot a preinstalled operating system, it may choose to only connect drivers to the devices that are required to boot the selected operating system. The UEFI Driver Model supports both these modes of operation through the boot services ConnectController() and DisconnectController() . In addition, since the platform component that is in charge of booting the platform has to work with device paths for console devices and boot options, all of the services and protocols involved in the UEFI Driver Model are optimized with device paths in mind.

Since the platform firmware may choose to only connect the devices required to produce consoles and gain access to a boot device, the OS present device drivers cannot assume that a UEFI driver for a device has been executed. The presence of a UEFI driver in the system firmware or in an option ROM does not guarantee that the UEFI driver will be loaded, executed, or allowed to manage any devices in a platform. All OS present device drivers must be able to handle devices that have been managed by a UEFI driver and devices that have not been managed by an UEFI driver.

The platform may also choose to produce a protocol named the Platform Driver Override Protocol. This is similar to the Bus Specific Driver Override Protocol, but it has higher priority. This gives the platform firmware the highest priority when deciding which drivers are connected to which controllers. The Platform Driver Override Protocol is attached to a handle in the system. The boot service ConnectController() will make use of this protocol if it is present in the system.

2.5.7 Hot-Plug Events

In the past, system firmware has not had to deal with hot-plug events in the preboot environment. However, with the advent of buses like USB, where the end user can add and remove devices at any time, it is important to make sure that it is possible to describe these types of buses in the UEFI Driver Model. It is up to the bus driver of a bus that supports the hot adding and removing of devices to provide support for such events. For these types of buses, some of the platform management is going to have to move into the bus drivers. For example, when a keyboard is hot added to a USB bus on a platform, the end user would expect the keyboard to be active. A USB Bus driver could detect the hot-add event and create a child handle for the keyboard device. However, because drivers are not connected to controllers unless *EFI_BOOT_SERVICES.ConnectController()* is called, the keyboard would not become an active input device. Making the keyboard driver active requires the USB Bus driver to call ConnectController() when a hot-add event occurs. In addition, the USB Bus Driver would have to call *EFI_BOOT_SERVICES.DisconnectController()* when a hot-remove event occurs. If EFI_BOOT_SERVICES.DisconnectController() returns an error the USB Bus Driver needs to retry the EFI_BOOT_SERVICES.DisconnectController() from a timer event until it succeeds.

Device drivers are also affected by these hot-plug events. In the case of USB, a device can be removed without any notice. This means that the Stop() functions of USB device drivers will have to deal with shutting down a driver for a device that is no longer present in the system. As a result, any outstanding I/O requests will have to be flushed without actually being able to touch the device hardware.

In general, adding support for hot-plug events greatly increases the complexity of both bus drivers and device drivers. Adding this support is up to the driver writer, so the extra complexity and size of the driver will need to be weighed against the need for the feature in the preboot environment.

2.5.8 EFI Services Binding

The UEFI *Driver Model* maps well onto hardware devices, hardware bus controllers, and simple combinations of software services that layer on top of hardware devices. However, the UEFI driver Model does not map well onto complex combinations of software services. As a result, an additional set of complementary protocols are required for more complex combinations of software services.

Figure below, *Software Service Relationships* , contains three examples showing the different ways that software services relate to each other. In the first two cases, each service consumes one or more other services, and at most one other service consumes all of the services. Case #3 differs because two different services consume service A. The EFI_DRIVER_BINDING_PROTOCOL can be used to model cases #1 and #2, but it cannot be used to model case #3 because of the way that the UEFI Boot Service OpenProtocol() behaves. When used with the BY_DRIVER open mode, OpenProtocol() allows each protocol to have only at most one consumer. This feature is very useful and prevents multiple drivers from attempting to manage the same controller. However, it makes it difficult to produce sets of software services that look like case #3.

Software Service Relationships The *EFI_SERVICE_BINDING_PROTOCOL* provides the mechanism that allows protocols to have more than one consumer. The *EFI_SERVICE_BINDING_PROTOCOL* is used with the *EFI_DRIVER_BINDING_PROTOCOL*. A UEFI driver that produces protocols that need to be available to more than one consumer at the same time will produce both the *EFI_DRIVER_BINDING_PROTOCOL* and the *EFI_SERVICE_BINDING_PROTOCOL*. This type of driver is a hybrid driver that will produce the *EFI_DRIVER_BINDING_PROTOCOL* in its driver entry point.

When the driver receives a request to start managing a controller, it will produce the *EFI_SERVICE_BINDING_PROTOCOL* on the handle of the controller that is being started. The *EFI_SERVICE_BINDING_PROTOCO*L is slightly different from other protocols defined in the UEFI Specification. It does not have a GUID associated with it. Instead, this protocol instance structure actually represents a family of protocols. Each software service driver that requires an *EFI_SERVICE_BINDING_PROTOCOL* instance will be required to generate a new GUID for its own type of *EFI_SERVICE_BINDING_PROTOCOL*. This requirement is why the various network protocols in this specification contain two GUIDs. One is the *EFI_SERVICE_BINDING_PROTOCOL* GUID for that network protocol, and the other GUID is for the protocol that

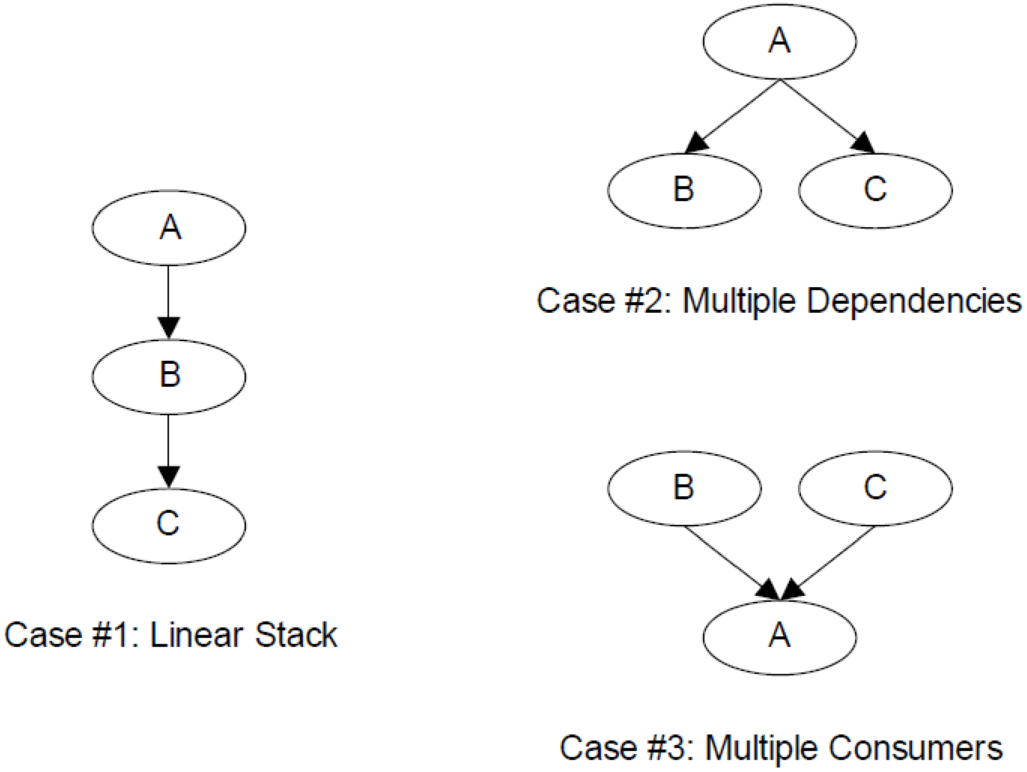

Fig. 2.14: Software Service Relationships

contains the specific member services produced by the network driver. The mechanism defined here is not limited to network protocol drivers. It can be applied to any set of protocols that the *EFI_DRIVER_BINDING_PROTOCOL* cannot directly map because the protocols contain one or more relationships like case #3 in *Software Service Relationships* .

Neither the *EFI_DRIVER_BINDING_PROTOCOL* nor the combination of the *EFI_DRIVER_BINDING_PROTOCOL* and the *EFI_SERVICE_BINDING_PROTOCOL* can handle circular dependencies. There are methods to allow circular references, but they require that the circular link be present for short periods of time. When the protocols across the circular link are used, these methods also require that the protocol must be opened with an open mode of EXCLUSIVE , so that any attempts to deconstruct the set of protocols with a call to DisconnectController() will fail. As soon as the driver is finished with the protocol across the circular link, the protocol should be closed.

2.6 Requirements

This document is an architectural specification. As such, care has been taken to specify architecture in ways that allow maximum flexibility in implementation. However, there are certain requirements on which elements of this specification must be implemented to ensure that operating system loaders and other code designed to run with UEFI boot services can rely upon a consistent environment.

For the purposes of describing these requirements, the specification is broken up into required and optional elements. In general, an optional element is completely defined in the section that matches the element name. For required elements however, the definition may in a few cases not be entirely self contained in the section that is named for the particular element. In implementing required elements, care should be taken to cover all the semantics defined in this specification that relate to the particular element.

2.6.1 Required Elements

Required UEFI Implementation Elements lists the required elements. Any system that is designed to conform to this specification must provide a complete implementation of all these elements. This means that all the required service functions and protocols must be present and the implementation must deliver the full semantics defined in the specification for all combinations of calls and parameters. Implementers of applications, drivers or operating system loaders that are designed to run on a broad range of systems conforming to the UEFI specification may assume that all such systems implement all the required elements.

A system vendor may choose not to implement all the required elements, for example on specialized system configurations that do not support all the services and functionality implied by the required elements. However, since most applications, drivers and operating system loaders are written assuming all the required elements are present on a system that implements the UEFI specification; any such code is likely to require explicit customization to run on a less than complete implementation of the required elements in this specification.

Table 2.12: Required UEFI Implementation Elements

Element	**Description**
EFI System Table	Provides access to UEFI Boot Services, UEFI Runtime Services, consoles, firmware vendor information, and the system configuration tables.
EFI_BOOT_SERVICES	All functions defined as boot services.
EFI_RUNTIME_SERVICES	All functions defined as runtime services.
EFI Loaded Image Protocol	Provides information on the image.
EFI Loaded Image Device Path Protocol	Specifies the device path that was used when a PE/COFF image was loaded through the EFI Boot Service LoadImage().

continues on next page

Table 2.12 – continued from previous page

EFI Device Path Protocol	Provides the location of the device.
EFI_DECOMPRESS_PROTOCOL	Protocol interfaces to decompress an image that was compressed using the EFI Compression Algorithm.
EFI_DEVICE_PATH_UTILITIES_PROTOCOL	Protocol interfaces to create and manipulate UEFI device paths and UEFI device path nodes.

2.6.2 Platform-Specific Elements

There are a number of elements that can be added or removed depending on the specific features that a platform requires. Platform firmware developers are required to implement UEFI elements based upon the features included. The following is a list of potential platform features and the elements that are required for each feature type:

1. If a platform includes console devices, the *EFI_SIMPLE_TEXT_INPUT_PROTOCOL*, *EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL*, and *EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL* must be implemented.
2. If a platform includes a configuration infrastructure, then *EFI_HII_DATABASE_PROTOCOL*, *EFI_HII_STRING_PROTOCOL*, *EFI HII Configuration Routing Protocol*, and *EFI_HII_CONFIG_ACCESS_PROTOCOL* are required. If you support bitmapped fonts, you must support *EFI_HII_FONT_PROTOCOL* .
3. If a platform includes graphical console devices, then *EFI_GRAPHICS_OUTPUT_PROTOCOL*, *EFI_EDID_DISCOVERED_PROTOCOL*, and *EFI_EDID_ACTIVE_PROTOCOL* must be implemented. In order to support the *EFI_GRAPHICS_OUTPUT_PROTOCOL* ; a platform must contain a driver to consume *EFI_GRAPHICS_OUTPUT_PROTOCOL* and produce *EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL* even if the *EFI_GRAPHICS_OUTPUT_PROTOCOL* is produced by an external driver.
4. If a platform includes a pointer device as part of its console support, *EFI_SIMPLE_POINTER_PROTOCOL* must be implemented.
5. If a platform includes the ability to boot from a disk device, then *EFI_BLOCK_IO_PROTOCOL*, *EFI_DISK_IO_PROTOCOL*, *EFI_SIMPLE_FILE_SYSTEM_PROTOCOL*, and *EFI_UNICODE_COLLATION_PROTOCOL* are required. In addition, partition support for MBR, GPT, and El Torito must be implemented. For disk devices supporting the security commands of the SPC-4 or ATA8-ACS command set *EFI_STORAGE_SECURITY_COMMAND_PROTOCOL* is also required. An external driver may produce the Block I/O Protocol and the *EFI_STORAGE_SECURITY_COMMAND_PROTOCOL* . All other protocols required to boot from a disk device must be carried as part of the platform.
6. If a platform includes the ability to perform a TFTP-based boot from a network device, then *EFI_PXE_BASE_CODE_PROTOCOL* is required. The platform must be prepared to produce this protocol on any of *EFI_NETWORK_INTERFACE_IDENTIFIER_PROTOCOL* (UNDI), *EFI_SIMPLE_NETWORK_PROTOCOL*, or *EFI Managed Network Protocol* . If a platform includes the ability to validate a boot image received through a network device, it is also required that image verification be supported, including SetupMode equal zero and the boot image hash or a verification certificate corresponding to the image exist in the 'db' variable and not in the 'dbx' variable. An external driver may produce the UNDI interface. All other protocols required to boot from a network device must be carried by the platform.
7. If a platform supports UEFI general purpose network applications, then the *EFI Managed Network Protocol*, *EFI_MANAGED_NETWORK_SERVICE_BINDING_PROTOCOL*, *EFI_ARP_PROTOCOL*, *EFI_ARP_SERVICE_BINDING_PROTOCOL*, *EFI_DHCP4_PROTOCOL*, *EFI_DHCP4_SERVICE_BINDING_PROTOCOL*, *EFI_TCP4_PROTOCOL*, *EFI_TCP4_SERVICE_BINDING_PROTOCOL*, *EFI_IP4_CONFIG2_PROTOCOL*, *EFI_IP4_SERVICE_BINDING_PROTOCOL*, *EFI_IP4_CONFIG2_PROTOCOL*, *EFI_UDP4_PROTOCOL*, and *EFI_UDP4_SERVICE_BINDING_PROTOCOL* are required. If additional IPv6 support is needed for the platform, then *EFI DHCP6 Protocol*, *EFI_DHCP6_SERVICE_BINDING_PROTOCOL*,

EFI_TCP6_PROTOCOL, *EFI_TCP6_SERVICE_BINDING_PROTOCOL*, *EFI_IP6_PROTOCOL*, *EFI_IP6_SERVICE_BINDING_PROTOCOL* , *EFI_IP6_CONFIG_PROTOCOL* *EFI_UDP6_PROTOCOL* . *EFI_UDP6_SERVICE_BINDING_PROTOCOL* are additionally required. If the network application requires DNS capability, *EFI_DNS4_SERVICE_BINDING_PROTOCOL* and *EFI_DNS4_PROTOCOL* are required for the IPv4 stack. *EFI_DNS6_SERVICE_BINDING_PROTOCOL* and *EFI_DNS6_PROTOCOL* are required for the IPv6 stack. If the network environment requires TLS feature, *EFI TLS Service Binding Protocol*, *EFI TLS Protocol* . *EFI TLS Configuration Protocol* are required. If the network environment requires IPSEC feature, *EFI_IPSEC_CONFIG_PROTOCOL* and *EFI IPsec2 Protocol* are required. If the network environment requires VLAN features, *EFI_VLAN_CONFIG_PROTOCOL* is required.

8. If a platform includes a byte-stream device such as a UART, then the *EFI_SERIAL_IO_PROTOCOL* must be implemented.
9. If a platform includes PCI bus support, then the *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL*, the *EFI PCI I/O Protocol*, must be implemented.
10. If a platform includes USB bus support, then *EFI_USB2_HC_PROTOCOL* and *EFI_USB_IO_PROTOCOL* must be implemented. An external device can support USB by producing a USB Host Controller Protocol.
11. If a platform includes an NVM Express controller, then *EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL* must be implemented.
12. If a platform supports booting from a block-oriented NVM Express controller, then *EFI_BLOCK_IO_PROTOCOL* must be implemented. An external driver may produce the *EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL* . All other protocols required to boot from an NVM Express subsystem must be carried by the platform.
13. If a platform includes an I/O subsystem that utilizes SCSI command packets, then *EFI_EXT_SCSI_PASS_THRU_PROTOCOL* must be implemented.
14. If a platform supports booting from a block oriented SCSI peripheral, then *EFI SCSI I/O Protocol* and *EFI_BLOCK_IO_PROTOCOL* must be implemented. An external driver may produce the *EFI_EXT_SCSI_PASS_THRU_PROTOCOL* . All other protocols required to boot from a SCSI I/O subsystem must be carried by the platform.
15. If a platform supports booting from an iSCSI peripheral, then the *EFI iSCSI Initiator Name Protocol* and *EFI_AUTHENTICATION_INFO_PROTOCOL* must be implemented.
16. If a platform includes debugging capabilities, then *EFI_DEBUG_SUPPORT_PROTOCOL*, the *EFI_DEBUGPORT_PROTOCOL*, and the *EFI Image Info* Table must be implemented.
17. If a platform includes the ability to override the default driver to the controller matching algorithm provided by the UEFI Driver Model, then *EFI Platform Driver Override Protocol* must be implemented.
18. If a platform includes an I/O subsystem that utilizes ATA command packets, then the *EFI_ATA_PASS_THRU_PROTOCOL* must be implemented.
19. If a platform supports option ROMs from devices not permanently attached to the platform and it supports the ability to authenticate those option ROMs, then it must support the option ROM validation methods described in *Network Protocols — UDP and MTFTP* and the authenticated EFI variables described in *Exception for Machine Check, INIT, and NMI* .
20. If a platform includes the ability to authenticate UEFI images and the platform potentially supports more than one OS loader, it must support the methods described in *Network Protocols — UDP and MTFTP* and the authenticated UEFI variables described in *Exception for Machine Check, INIT, and NMI*.
21. EBC support is no longer required as of UEFI Specification version 2.8. If an EBC interpreter is implemented, then it must produce the EFI_EBC_PROTOCOL interface.
22. If a platform includes the ability to perform a HTTP-based boot from a network device, then the *EFI_HTTP_SERVICE_BINDING_PROTOCOL*, *EFI_HTTP_PROTOCOL* and

EFI_HTTP_UTILITIES_PROTOCOL are required. If it includes the ability to perform a HTTPS-based boot from network device, besides above protocols *EFI TLS Service Binding Protocol*, *EFI TLS Protocol* and *EFI TLS Configuration Protocol* are also required. If it includes the ability to perform a HTTP(S)-based boot with DNS feature, then *EFI_DNS4_SERVICE_BINDING_PROTOCOL*, *EFI_DNS4_PROTOCOL* are required for the IPv4 stack; *EFI_DNS6_SERVICE_BINDING_PROTOCOL* and *EFI_DNS6_PROTOCOL* are required for the IPv6 stack.

23. If a platform includes the ability to perform a wireless boot from a network device with EAP feature, and if this platform provides a standalone wireless EAP driver, then *EFI_EAP_PROTOCOL*, *EFI EAP Configuration Protocol*, and *EFI EAP Management2 Protocol* are required; if the platform provides a standalone wireless supplicant, then *EFI Supplicant Protocol* and *EFI EAP Configuration Protocol* are required. If it includes the ability to perform a wireless boot with TLS feature, then *EFI TLS Service Binding Protocol*, *EFI TLS Protocol* and *EFI TLS Configuration Protocol* are required.
24. If a platform supports classic Bluetooth, then *EFI_BLUETOOTH_HC_PROTOCOL*, *EFI_BLUETOOTH_IO_PROTOCOL*, and *EFI_BLUETOOTH_CONFIG_PROTOCOL* must be implemented, and *EFI Bluetooth Attribute Protocol* may be implemented. If a platform supports Bluetooth Smart (Bluetooth Low Energy), then *EFI_BLUETOOTH_HC_PROTOCOL*, *EFI Bluetooth Attribute Protocol* and *EFI_BLUETOOTH_LE_CONFIG_PROTOCOL* must be implemented. If a platform supports both Bluetooth classic and BluetoothLE, then both above requirements should be satisfied.
25. If a platform supports RESTful communication over HTTP or over an in-band path to a BMC, then the *EFI REST Protocol* or EFI_REST_EX_PROTOCOL must be implemented. If EFI_REST_EX_PROTOCOL is implemented, EFI_REST_EX_SERVICE_BINDING_PROTOCOL must be implemented as well. If a platform supports Redfish communication over HTTP or over an in-band path to a BMC, the EFI_REDFISH_DISCOVER_PROTOCOL and *EFI REST JSON Structure Protocol* may be implemented.
26. If a platform includes the ability to use a hardware feature to create high quality random numbers, this capability should be exposed by instance of *EFI_RNG_PROTOCOL* with at least one EFI RNG Algorithm supported.
27. If a platform permits the installation of Load Option Variables, (Boot####, or Driver####, or SysPrep####), the platform must support and recognize all defined values for Attributes within the variable and report these capabilities in BootOptionSupport. If a platform supports installation of Load Option Variables of type Driver####, all installed Driver#### variables must be processed and the indicated driver loaded and initialized during every boot. And all installed SysPrep#### options must be processed prior to processing Boot#### options.
28. If the platform supports UEFI secure boot as described in *Secure Boot and Driver Signing*, the platform must provide the PKCS verification functions described in *PKCS7 Verify Protocol* .
29. If a platform includes an I/O subsystem that utilizes SD or eMMC command packets, then the *EFI_SD_MMC_PASS_THRU_PROTOCOL* must be implemented.
30. If a platform includes the ability to create/destroy a specified RAM disk, the *EFI_RAM_DISK_PROTOCOL* must be implemented and only one instance of this protocol exists.
31. If a platform includes a mass storage device which supports hardware-based erase on a specified range, then *EFI_ERASE_BLOCK_PROTOCOL* must be implemented.
32. If a platform includes the ability to register for notifications when a call to ResetSystem is called, then the *EFI_RESET_NOTIFICATION_PROTOCOL* must be implemented.
33. If a platform includes UFS devices, the *EFI UFS Device Config Protocol* must be implemented.
34. If a platform cannot support calls defined in *EFI_RUNTIME_SERVICES* after ExitBootServices() is called, that platform is permitted to provide implementations of those runtime services that return EFI_UNSUPPORTED when invoked at runtime. On such systems, an EFI_RT_PROPERTIES_TABLE configuration table should be published describing which runtime services are supported at runtime.
35. If a platform includes support for CXL devices with coherent memory, then the platform must support extracting the Coherent Device Attribute Table (CDAT) from the device, using either the CXL Data Object Exchange ser-

vices (as defined in the CXL 2.0 Specification) or the EFI_ADAPTER_INFORMATION_PROTOCOL instance (with EFI_ADAPTER_INFO_CDAT_TYPE_GUID type) installed on that device.

Note: *Some of the required protocol instances are created by the corresponding Service Binding Protocol. For example*, EFI_IP4_PROTOCOL *is created by* EFI_IP4_SERVICE_BINDING_PROTOCOL. *Please refer to the corresponding sections of Service Binding Protocol for the details*.

2.6.3 Driver-Specific Elements

There are a number of UEFI elements that can be added or removed depending on the features that a specific driver requires. Drivers can be implemented by platform firmware developers to support buses and devices in a specific platform. Drivers can also be implemented by add-in card vendors for devices that might be integrated into the platform hardware or added to a platform through an expansion slot.

The following list includes possible driver features, and the UEFI elements that are required for each feature type:

1. If a driver follows the driver model of this specification, the *EFI Driver Binding Protocol* must be implemented. It is strongly recommended that all drivers that follow the driver model of this specification also implement the *EFI_COMPONENT_NAME2_PROTOCOL* .
2. If a driver requires configuration information, the driver must use the *EFI_HII_DATABASE_PROTOCOL* . A driver should not otherwise display information to the user or request information from the user.
3. If a driver requires diagnostics, the *EFI_DRIVER_DIAGNOSTICS2_PROTOCOL* must be implemented. In order to support low boot times, limit diagnostics during normal boots. Time consuming diagnostics should be deferred until the *EFI_DRIVER_DIAGNOSTICS2_PROTOCOL* is invoked.
4. If a bus supports devices that are able to provide containers for drivers (e.g. option ROMs), then the bus driver for that bus type must implement the *EFI_BUS_SPECIFIC_DRIVER_OVERRIDE_PROTOCOL* .
5. If a driver is written for a console output device, then the *EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL* must be implemented.
6. If a driver is written for a graphical console output device, then the *EFI_GRAPHICS_OUTPUT_PROTOCOL*, *EFI_EDID_DISCOVERED_PROTOCOL* and *EFI_EDID_ACTIVE_PROTOCOL* must be implemented.
7. If a driver is written for a console input device, then the *EFI_SIMPLE_TEXT_INPUT_PROTOCOL* and *EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL* must be implemented.
8. If a driver is written for a pointer device, then the *EFI_SIMPLE_POINTER_PROTOCOL* must be implemented.
9. If a driver is written for a network device, then the *EFI_NETWORK_INTERFACE_IDENTIFIER_PROTOCOL*, *EFI_SIMPLE_NETWORK_PROTOCOL* or *EFI Managed Network Protocol* must be implemented. If VLAN is supported in hardware, then driver for the network device may implement the *EFI_VLAN_CONFIG_PROTOCOL* . If a network device chooses to only produce the *EFI Managed Network Protocol*, then the driver for the network device must implement the *EFI_VLAN_CONFIG_PROTOCOL* . If a driver is written for a network device to supply wireless feature, besides above protocols, *EFI_ADAPTER_INFORMATION_PROTOCOL* must be implemented. If the wireless driver does not provide user configuration capability, *EFI Wireless MAC Connection II Protocol* must be implemented. If the wireless driver is written for a platform which provides a standalone wireless EAP driver, *EFI_EAP_PROTOCOL* must be implemented.
10. If a driver is written for a disk device, then the :ref:` efi-block-io-protocol` and the *EFI_BLOCK_IO2_PROTOCOL* must be implemented. In addition, the *EFI_STORAGE_SECURITY_COMMAND_PROTOCOL* must be implemented for disk devices supporting the security commands of the SPC-4 or ATA8-ACS command set. In addition, for devices that support incline encryption in the host storage controller, the *EFI_BLOCK_IO_CRYPTO_PROTOCOL* must be supported.
11. If a driver is written for a disk device, then the *EFI_BLOCK_IO_PROTOCOL* and the *EFI_BLOCK_IO2_PROTOCOL* must be implemented. In addition, the

EFI_STORAGE_SECURITY_COMMAND_PROTOCOL must be implemented for disk devices supporting the security commands of the SPC-4 or ATA8-ACS command set.

12. If a driver is written for a device that is not a block oriented device but one that can provide a file system-like interface, then the *EFI_SIMPLE_FILE_SYSTEM_PROTOCOL* must be implemented.
13. If a driver is written for a PCI root bridge, then the *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL* and the *EFI PCI I/O Protocol* must be implemented.
14. If a driver is written for an NVM Express controller, then the *EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL* must be implemented.
15. If a driver is written for a USB host controller, then the *EFI_USB2_HC_PROTOCOL* and the *EFI_USB_IO_PROTOCOL* must be implemented.If a driver is written for a USB host controller, then the must be implemented. TODO MISSING WORD END OF LAST SENTENCE
16. If a driver is written for a SCSI controller, then the *EFI_EXT_SCSI_PASS_THRU_PROTOCOL* must be implemented.
17. If a driver is digitally signed, it must embed the digital signature in the PE/COFF image as described in *Embedded Signatures* .
18. If a driver is written for a boot device that is not a block-oriented device, a file system-based device, or a console device, then the *EFI_LOAD_FILE2_PROTOCOL* must be implemented.
19. If a driver follows the driver model of this specification, and the driver wants to produce warning or error messages for the user, then the *EFI Driver Health Protocol* must be used to produce those messages. The Boot Manager may optionally display the messages to the user.
20. If a driver follows the driver model of this specification, and the driver needs to perform a repair operation that is not part of the normal initialization sequence, and that repair operation requires an extended period of time, then the *EFI Driver Health Protocol* must be used to provide the repair feature. If the Boot Manager detects a boot device that requires a repair operation, then the Boot Manager must use the *EFI Driver Health Protocol* to perform the repair operation. The Boot Manager can optionally display progress indicators as the repair operation is performed by the driver.
21. If a driver follows the driver model of this specification, and the driver requires the user to make software and/or hardware configuration changes before the boot devices that the driver manages can be used, then the *EFI Driver Health Protocol* must be produced. If the Boot Manager detects a boot device that requires software and/or hardware configuration changes to make the boot device usable, then the Boot Manager may optionally allow the user to make those configuration changes.
22. If a driver is written for an ATA controller, then the *EFI_ATA_PASS_THRU_PROTOCOL* must be implemented.
23. If a driver follows the driver model of this specification, and the driver wants to be used with higher priority than the Bus Specific Driver Override Protocol when selecting the best driver for controller, then the *EFI_DRIVER_FAMILY_OVERRIDE_PROTOCOL* must be produced on the same handle as the :ref:` efi-driver-binding-protocol-protocols-uefi-driver-model` .
24. If a driver supports firmware management by an external agent or application, then the *EFI_FIRMWARE_MANAGEMENT_PROTOCOL* must be used to support firmware management.
25. If a driver follows the driver model of this specification and a driver is a device driver as defined in *UEFI Driver Model*, it must perform bus transactions via the bus abstraction protocol produced by a parent bus driver. Thus a driver for a device that conforms to the PCI specification must use *EFI PCI I/O Protocol* for all PCI memory space, PCI I/O, PCI configuration space, and DMA operations.
26. If a driver is written for a classic Bluetooth controller, then *EFI_BLUETOOTH_HC_PROTOCOL*, *EFI_BLUETOOTH_IO_PROTOCOL* and *EFI_BLUETOOTH_CONFIG_PROTOCOL* must be implemented, and *EFI Bluetooth Attribute Protocol* may be implemented. If a driver written for a Bluetooth Smart (Bluetooth Low Energy) controller, then *EFI_BLUETOOTH_HC_PROTOCOL*, *EFI Bluetooth Attribute Protocol* and

EFI_BLUETOOTH_LE_CONFIG_PROTOCOL must be implemented. If a driver supports both Bluetooth classic and BluetoothLE, then both above requirements should be satisfied.

27. If a driver is written for an SD controller or eMMC controller, then the *EFI_SD_MMC_PASS_THRU_PROTOCOL* must be implemented.
28. If a driver is written for a UFS device, then EFI_UFS_DEVICE_CONFIG_PROTOCOL must be implemented.

2.6.4 Extensions to this Specification Published Elsewhere

This specification has been extended over time to include support for new devices and technologies. As the name of the specification implies, the original intent in its definition was to create a baseline for firmware interfaces that is extensible without the need to include extensions in the main body of this specification.

Readers of this specification may find that a feature or type of device is not treated by the specification. This does not necessarily mean that there is no agreed "standard" way to support the feature or device in implementations that claim conformance to this Specification. On occasion, it may be more appropriate for other standards organizations to publish their own extensions that are designed to be used in concert with the definitions presented here. This may for example allow support for new features in a more timely fashion than would be accomplished by waiting for a revision to this specification or perhaps that such support is defined by a group with a specific expertise in the subject area. Readers looking for means to access features or devices that are not treated in this document are therefore recommended to inquire of appropriate standards groups to ascertain if appropriate extension publications already exist before creating their own extensions.

By way of examples, at the time of writing the UEFI Forum is aware of a number of extension publications that are compatible with and designed for use with this specification. Such extensions include:

- *Developers Interface Guide for Itanium® Architecture Based Servers*: published and hosted by the DIG64 group (See "Links to UEFI-Related Documents" (http://uefi.org/uefi) under the heading "Developers Interface Guide for Itanium® Architecture Based Servers"). This document is a set of technical guidelines that define hardware, firmware, and operating system compatibility for Itanium™-based servers;
- *TCG EFI Platform Specification*: published and hosted by the Trusted Computing Group (See "Links to UEFI-Related Documents" (http://uefi.org/uefi) under the heading "TCG EFI Platform Specification"). This document is about the processes that boot an EFI platform and boot an OS on that platform. Specifically, this specification contains the requirements for measuring boot events into TPM PCRs and adding boot event entries into the Event Log.
- *TCG EFI Protocol Specification*: published and hosted by the Trusted Computing Group (See "Links to UEFI-Related Documents" (http://uefi.org/uefi) under the heading "TCG EFI Protocol Specification"). This document defines a standard interface to the TPM on an EFI platform.

Other extension documents may exist outside the view of the UEFI Forum or may have been created since the last revision of this document.

CHAPTER

THREE

BOOT MANAGER

The UEFI boot manager is a firmware policy engine that can be configured by modifying architecturally defined global NVRAM variables. The boot manager will attempt to load UEFI drivers and UEFI applications (including UEFI OS boot loaders) in an order defined by the global NVRAM variables. The platform firmware must use the boot order specified in the global NVRAM variables for normal boot. The platform firmware may add extra boot options or remove invalid boot options from the boot order list.

The platform firmware may also implement value added features in the boot manager if an exceptional condition is discovered in the firmware boot process. One example of a value added feature would be not loading a UEFI driver if booting failed the first time the driver was loaded. Another example would be booting to an OEM-defined diagnostic environment if a critical error was discovered in the boot process.

The boot sequence for UEFI consists of the following:

- The boot order list is read from a globally defined NVRAM variable. Modifications to this variable are only guaranteed to take effect after the next platform reset. The boot order list defines a list of NVRAM variables that contain information about what is to be booted. Each NVRAM variable defines a name for the boot option that can be displayed to a user.
- The variable also contains a pointer to the hardware device and to a file on that hardware device that contains the UEFI image to be loaded.
- The variable might also contain paths to the OS partition and directory along with other configuration specific directories.

The NVRAM can also contain load options that are passed directly to the UEFI image. The platform firmware has no knowledge of what is contained in the load options. The load options are set by higher level software when it writes to a global NVRAM variable to set the platform firmware boot policy. This information could be used to define the location of the OS kernel if it was different than the location of the UEFI OS loader.

3.1 Firmware Boot Manager

The boot manager is a component in firmware conforming to this specification that determines which drivers and applications should be explicitly loaded and when. Once compliant firmware is initialized, it passes control to the boot manager. The boot manager is then responsible for determining what to load and any interactions with the user that may be required to make such a decision.

The actions taken by the boot manager depend upon the system type and the policies set by the system designer. For systems that allow the installation of new Boot Variables (See *Boot Option Recovery*), the Boot Manager must automatically or upon the request of the loaded item, initialize at least one system console, as well as perform all required initialization of the device indicated within the primary boot target. For such systems, the Boot Manager is also required to honor the priorities set in BootOrder variable.

In particular, likely implementation options might include any console interface concerning boot, integrated platform management of boot selections, and possible knowledge of other internal applications or recovery drivers that may be integrated into the system through the boot manager.

3.1.1 Boot Manager Programming

Programmatic interaction with the boot manager is accomplished through globally defined variables. On initialization the boot manager reads the values which comprise all of the published load options among the UEFI environment variables. By using the *SetVariable()* function the data that contain these environment variables can be modified. Such modifications are guaranteed to take effect after the next system boot commences. However, boot manager implementations may choose to improve on this guarantee and have changes take immediate effect for all subsequent accesses to the variables that affect boot manager behavior without requiring any form of system reset.

Each load option entry resides in a *Boot####*, *Driver####*, *SysPrep####*, *OsRecovery####* or *PlatformRecovery####* variable where *####* is replaced by a unique option number in printable hexadecimal representation using the digits 0-9, and the upper case versions of the characters A-F (0000-FFFF).

The *####* must always be four digits, so small numbers must use leading zeros. The load options are then logically ordered by an array of option numbers listed in the desired order. There are two such option ordering lists when booting normally. The first is *DriverOrder* that orders the *Driver####* load option variables into their load order. The second is *BootOrder* that orders the *Boot####* load options variables into their load order.

For example, to add a new boot option, a new *Boot####* variable would be added. Then the option number of the new *Boot####* variable would be added to the *BootOrder* ordered list and the *BootOrder* variable would be rewritten. To change boot option on an existing *Boot####* , only the *Boot####* variable would need to be rewritten. A similar operation would be done to add, remove, or modify the driver load list.

If the boot via *Boot####* returns with a status of *EFI_SUCCESS* , platform firmware supports boot manager menu, and if firmware is configured to boot in an interactive mode, the boot manager will stop processing the *BootOrder* variable and present a boot manager menu to the user. If any of the above-mentioned conditions is not satisfied, the next *Boot####* in the *BootOrder* variable will be tried until all possibilities are exhausted. In this case, boot option recovery must be performed (See *Boot Option Recovery*).

The boot manager may perform automatic maintenance of the database variables. For example, it may remove unreferenced load option variables or any load option variables that cannot be parsed, and it may rewrite any ordered list to remove any load options that do not have corresponding load option variables. The boot manager can also, at its own discretion, provide an administrator with the ability to invoke manual maintenance operations as well. Examples include choosing the order of any or all load options, activating or deactivating load options, initiating OS-defined or platform-defined recovery, etc. In addition, if a platform intends to create *PlatformRecovery####* , before attempting to load and execute any *DriverOrder* or *BootOrder* entries, the firmware must create any and all *PlatformRecovery####* variables (See *Platform-Defined Boot Option Recovery*). The firmware should not, under normal operation, automatically remove any correctly formed Boot#### variable currently referenced by the *BootOrder* or *BootNext* variables. Such removal should be limited to scenarios where the firmware is guided by direct user interaction.

The contents of *PlatformRecovery####* represent the final recovery options the firmware would have attempted had recovery been initiated during the current boot, and need not include entries to reflect contingencies such as significant hardware reconfiguration, or entries corresponding to specific hardware that the firmware is not yet aware of.

The behavior of the UEFI Boot Manager is impacted when Secure Boot is enabled, *Firmware/OS Key Exchange: Passing Public Keys*.

3.1.2 Load Option Processing

The boot manager is required to process the Driver load option entries before the Boot load option entries. If the *EFI_OS_INDICATIONS_START_OS_RECOVERY* bit has been set in *OsIndications* , the firmware shall attempt OS-defined recovery (See *OS-Defined Boot Option Recovery*) rather than normal boot processing. If the *EFI_OS_INDICATIONS_START_PLATFORM_RECOVERY* bit has been set in *OsIndications* , the firmware shall attempt platform-defined recovery (See :ref:` platform-defined-boot-option-recovery_boot_manager`) rather than normal boot processing or handling of the *EFI_OS_INDICATIONS_START_OS_RECOVERY* bit. In either case, both bits should be cleared.

Otherwise, the boot manager is also required to initiate a boot of the boot option specified by the *BootNext* variable as the first boot option on the next boot, and only on the next boot. The boot manager removes the *BootNext* variable before transferring control to the *BootNext* boot option. After the *BootNext* boot option is tried, the normal *BootOrder* list is used. To prevent loops, the boot manager deletes *BootNext* before transferring control to the preselected boot option.

If all entries of *BootNext* and *BootOrder* have been exhausted without success, or if the firmware has been instructed to attempt boot order recovery, the firmware must attempt boot option recovery (See *Boot Option Recovery*).

The boot manager must call *EFI_BOOT_SERVICES.LoadImage()* which supports at least *EFI_SIMPLE_FILE_SYSTEM_PROTOCOL* and *EFI_LOAD_FILE_PROTOCOL* for resolving load options. If *LoadImage()* succeeds, the boot manager must enable the watchdog timer for 5 minutes by using the *EFI_BOOT_SERVICES.SetWatchdogTimer()* boot service prior to calling *EFI_BOOT_SERVICES.StartImage()*. If a boot option returns control to the boot manager, the boot manager must disable the watchdog timer with an additional call to the *SetWatchdogTimer()* boot service.

If the boot image is not loaded via *EFI_BOOT_SERVICES.LoadImage()* the boot manager is required to check for a default application to boot. Searching for a default application to boot happens on both removable and fixed media types. This search occurs when the device path of the boot image listed in any boot option points directly to an *EFI_SIMPLE_FILE_SYSTEM_PROTOCOL* device and does not specify the exact file to load. The file discovery method is explained in *Boot Option Recovery*. The default media boot case of a protocol other than *EFI_SIMPLE_FILE_SYSTEM_PROTOCOL* is handled by the *EFI_LOAD_FILE_PROTOCOL* for the target device path and does not need to be handled by the boot manager.

The UEFI boot manager must support booting from a short-form device path that starts with the first element being a USB WWID (*USB WWID Device Path*) or a USB Class (*USB Class Device Path*) device path. For USB WWID, the boot manager must use the device vendor ID, device product id, and serial number, and must match any USB device in the system that contains this information. If more than one device matches the USB WWID device path, the boot manager will pick one arbitrarily. For USB Class, the boot manager must use the vendor ID, Product ID, Device Class, Device Subclass, and Device Protocol, and must match any USB device in the system that contains this information. If any of the ID, Product ID, Device Class, Device Subclass, or Device Protocol contain all F's (0xFFFF or 0xFF), this element is skipped for the purpose of matching. If more than one device matches the USB Class device path, the boot manager will pick one arbitrarily.

The boot manager must also support booting from a short-form device path that starts with the first element being a hard drive media device path (*Hard Drive Media Device Path*). The boot manager must use the GUID or signature and partition number in the hard drive device path to match it to a device in the system. If the drive supports the GPT partitioning scheme the GUID in the hard drive media device path is compared with the *UniquePartitionGuid* field of the GUID Partition Entry (*GPT Partition Entry*). If the drive supports the PC-AT MBR scheme the signature in the hard drive media device path is compared with the *UniqueMBRSignature* in the Legacy Master Boot Record (*Legacy MBR*). If a signature match is made, then the partition number must also be matched. The hard drive device path can be appended to the matching hardware device path and normal boot behavior can then be used. If more than one device matches the hard drive device path, the boot manager will pick one arbitrarily. Thus the operating system must ensure the uniqueness of the signatures on hard drives to guarantee deterministic boot behavior.

The boot manager must also support booting from a short-form device path that starts with the first element being a File Path Media Device Path (*File Path Media Device Path*). When the boot manager attempts to boot a short-form File

Path Media Device Path, it will enumerate all removable media devices, followed by all fixed media devices, creating boot options for each device. The boot option FilePathList[0] is constructed by appending short-form File Path Media Device Path to the device path of a media. The order within each group is undefined. These new boot options must not be saved to non volatile storage, and may not be added to *BootOrder*. The boot manager will then attempt to boot from each boot option. If a device does not support the *EFI_SIMPLE_FILE_SYSTEM_PROTOCOL* , but supports the *EFI_BLOCK_IO_PROTOCOL* protocol, then the EFI Boot Service *ConnectController* must be called for this device with *DriverImageHandle* and *RemainingDevicePath* set to NULL and the Recursive flag is set to *TRUE*. The firmware will then attempt to boot from any child handles produced using the algorithms outlined above.

The boot manager must also support booting from a short-form device path that starts with the first element being a URI Device Path (*URI Device Path*). When the boot manager attempts to boot a short-form URI Device Path, it could attempt to connect any device which will produce a device path protocol including a URI device path node until it matches a device, or fail to match any device. The boot manager will enumerate all *LoadFile* protocol instances, and invoke *LoadFile* protocol with *FilePath* set to the short-form device path during the matching process.

3.1.3 Load Options

Each load option variable contains an *EFI_LOAD_OPTION* descriptor that is a byte packed buffer of variable length fields.

```
typedef struct _EFI_LOAD_OPTION {
  UINT32                            Attributes;
  UINT16                            FilePathListLength;
  // CHAR16                         Description[];
  // EFI_DEVICE_PATH_PROTOCOL       FilePathList[];
  // UINT8                          OptionalData[];
}   EFI_LOAD_OPTION;
```

Parameters

Attributes
The attributes for this load option entry. All unused bits must be zero and are reserved by the UEFI specification for future growth. See “Related Definitions.”

FilePathListLength
Length in bytes of the FilePathList. OptionalData starts at offset sizeof(UINT32) + sizeof(UINT16) + StrSize(Description) + FilePathListLength of the EFI_LOAD_OPTION descriptor.

Description
The user readable description for the load option. This field ends with a Null character.

FilePathList
A packed array of UEFI device paths. The first element of the array is a device path that describes the device and location of the Image for this load option. The FilePathList[0] is specific to the device type. Other device paths may optionally exist in the FilePathList, but their usage is OSV specific. Each element in the array is variable length, and ends at the device path end structure. Because the size of Description is arbitrary, this data structure is not guaranteed to be aligned on a natural boundary. This data structure may have to be copied to an aligned natural boundary before it is used.

OptionalData
The remaining bytes in the load option descriptor are a binary data buffer that is passed to the loaded image. If the field is zero bytes long, a NULL pointer is passed to the loaded image. The number of bytes in OptionalData can be computed by subtracting the starting offset of OptionalData from total size in bytes of the EFI_LOAD_OPTION.

Note: Each device path in the FilePathList can be a single instance or a multi-instance device path.

Related Definitions

```
//*******************************************************
// Attributes
//*******************************************************
#define LOAD_OPTION_ACTIVE                0x00000001
#define LOAD_OPTION_FORCE_RECONNECT       0x00000002
#define LOAD_OPTION_HIDDEN                0x00000008
#define LOAD_OPTION_CATEGORY              0x00001F00

#define LOAD_OPTION_CATEGORY_BOOT         0x00000000
#define LOAD_OPTION_CATEGORY_APP          0x00000100
// All values 0x00000200-0x00001F00 are reserved
```

Description

Calling *SetVariable()* creates a load option. The size of the load option is the same as the size of the *DataSize* argument to the *SetVariable()* call that created the variable. When creating a new load option, all undefined attribute bits must be written as zero. When updating a load option, all undefined attribute bits must be preserved.

If a load option is marked as *LOAD_OPTION_ACTIVE,* the boot manager will attempt to boot automatically using the device path information in the load option. This provides an easy way to disable or enable load options without needing to delete and re-add them.

If any *Driver####* load option is marked as *LOAD_OPTION_FORCE_RECONNECT* , then all of the UEFI drivers in the system will be disconnected and reconnected after the last *Driver####* load option is processed. This allows a UEFI driver loaded with a *Driver####* load option to override a UEFI driver that was loaded prior to the execution of the UEFI Boot Manager.

The executable indicated by *FilePathList[0]* in *Driver####* load option must be of type *EFI_IMAGE_SUBSYSTEM_EFI_BOOT_SERVICE_DRIVER* or *EFI_IMAGE_SUBSYSTEM_EFI_RUNTIME_DRIVER* otherwise the indicated executable will not be entered for initialization.

The executable indicated by *FilePathList[0]* in *SysPrep###* , *Boot####* , or *OsRecovery####* load option must be of type *EFI_IMAGE_SUBSYSTEM_EFI_APPLICATION,* otherwise the indicated executable will not be entered.

The *LOAD_OPTION_CATEGORY* is a sub-field of Attributes that provides details to the boot manager to describe how it should group the *Boot####* load options. This field is ignored for variables of the form *Driver####* , *SysPrep####,* or *OsRecovery####.*

Boot#### load options with *LOAD_OPTION_CATEGORY* set to *LOAD_OPTION_CATEGORY_BOOT* are meant to be part of the normal boot processing.

Boot#### load options with *LOAD_OPTION_CATEGORY* set to *LOAD_OPTION_CATEGORY_APP* are executables which are not part of the normal boot processing but can be optionally chosen for execution if boot menu is provided, or via Hot Keys. See See *Launching Boot#### Load Options Using Hot Keys* for details.

Boot options with reserved category values, will be ignored by the boot manager.

If any *Boot####* load option is marked as *LOAD_OPTION_HIDDEN* , then the load option will not appear in the menu (if any) provided by the boot manager for load option selection.

3.1.4 Boot Manager Capabilities

The boot manager can report its capabilities through the global variable *BootOptionSupport*. If the global variable is not present, then an installer or application must act as if a value of 0 was returned.

```
#define EFI_BOOT_OPTION_SUPPORT_KEY          0x00000001
#define EFI_BOOT_OPTION_SUPPORT_APP          0x00000002
#define EFI_BOOT_OPTION_SUPPORT_SYSPREP      0x00000010
#define EFI_BOOT_OPTION_SUPPORT_COUNT        0x00000300
```

If *EFI_BOOT_OPTION_SUPPORT_KEY* is set then the boot manager supports launching of *Boot####* load options using key presses. If *EFI_BOOT_OPTION_SUPPORT_APP* is set then the boot manager supports boot options with *LOAD_OPTION_CATEGORY_APP*. If *EFI_BOOT_OPTION_SUPPORT_SYSPREP* is set then the boot manager supports boot options of form *SysPrep####*.

The value specified in *EFI_BOOT_OPTION_SUPPORT_COUNT* describes the maximum number of key presses which the boot manager supports in the *EFI_KEY_OPTION .KeyData.InputKeyCount*. This value is only valid if *EFI_BOOT_OPTION_SUPPORT_KEY* is set. Key sequences with more keys specified are ignored.

3.1.5 Launching Boot#### Applications

The boot manager may support a separate category of *Boot####* load option for applications. The boot manager indicates that it supports this separate category by setting the *EFI_BOOT_OPTION_SUPPORT_APP* in the *BootOptionSupport* global variable.

When an application's *Boot####* option is being added to the *BootOrder* , the installer should clear *LOAD_OPTION_ACTIVE* so that the boot manager does not attempt to automatically "boot" the application. If the boot manager indicates that it supports a separate application category, as described above, the installer should set *LOAD_OPTION_CATEGORY_APP*. If not, it should set *LOAD_OPTION_CATEGORY_BOOT*.

3.1.6 Launching Boot#### Load Options Using Hot Keys

The boot manager may support launching a Boot#### load option using a special key press. If so, the boot manager reports this capability by setting EFI_BOOT_OPTION_SUPPORT_KEY in the BootOptionSupport global variable.

A boot manager which supports key press launch reads the current key information from the console. Then, if there was a key press, it compares the key returned against zero or more *Key####* global variables. If it finds a match, it verifies that the *Boot####* load option specified is valid and, if so, attempts to launch it immediately. The #### in the *Key####* is a printable hexadecimal number ('0'-'9', 'A'-'F') with leading zeroes. The order which the *Key####* variables are checked is implementation-specific.

The boot manager may ignore *Key####* variables where the hot keys specified overlap with those used for internal boot manager functions. It is recommended that the boot manager delete these keys.

The *Key####* variables have the following format:

Prototype

```
typedef struct _EFI_KEY_OPTION {
  EFI_BOOT_KEY_DATA          KeyData;
  UINT32                     BootOptionCrc;
  UINT16                     BootOption;
// EFI_INPUT_KEY             Keys[];
}   EFI_KEY_OPTION;
```

Parameters

KeyData

Specifies options about how the key will be processed. Type EFI_BOOT_KEY_DATA is defined in “Related Definitions” below.

BootOptionCrc

The CRC-32 which should match the CRC-32 of the entire EFI_LOAD_OPTION to which BootOption refers. If the CRC-32s do not match this value, then this key option is ignored.

BootOption

The Boot#### option which will be invoked if this key is pressed and the boot option is active (LOAD_OPTION_ACTIVE is set).

Keys

The key codes to compare against those returned by the EFI_SIMPLE_TEXT_INPUT and EFI_SIMPLE_TEXT_INPUT_EX protocols. The number of key codes (0-3) is specified by the EFI_KEY_CODE_COUNT field in KeyOptions.

Related Definitions

```
typedef union {
  struct {
    UINT32   Revision : 8;
    UINT32   ShiftPressed : 1;
    UINT32   ControlPressed : 1;
    UINT32   AltPressed : 1;
    UINT32   LogoPressed : 1;
    UINT32   MenuPressed : 1;
    UINT32   SysReqPressed : 1;
    UINT32   Reserved : 16;
    UINT32   InputKeyCount : 2;
    } Options;
  UINT32 PackedValue;
} EFI_BOOT_KEY_DATA;
```

Revision

Indicates the revision of the *EFI_KEY_OPTION* structure. This revision level should be 0.

ShiftPressed

Either the left or right Shift keys must be pressed (1) or must not be pressed (0).

ControlPressed

Either the left or right Control keys must be pressed (1) or must not be pressed (0).

AltPressed

Either the left or right Alt keys must be pressed (1) or must not be pressed (0).

LogoPressed

Either the left or right Logo keys must be pressed (1) or must not be pressed (0).

MenuPressed

The Menu key must be pressed (1) or must not be pressed (0).

SysReqPressed

The SysReq key must be pressed (1) or must not be pressed (0).

InputKeyCount

Specifies the actual number of entries in EFI_KEY_OPTION. Keys, from 0-3. If zero, then only the shift state is considered. If more than one, then the boot option will only be launched if all of the specified keys are pressed with the same shift state.

Example #1: ALT is the hot key. *KeyData.PackedValue = 0x00000400*.

Example #2: CTRL-ALT-P-R. *KeyData.PackedValue = 0x80000600*.

Example #3: CTRL-F1. *KeyData.PackedValue = 0x40000200*.

3.1.7 Required System Preparation Applications

A load option of the form *SysPrep####* is intended to designate a UEFI application that is required to execute in order to complete system preparation prior to processing of any *Boot####* variables. The execution order of *SysPrep####* applications is determined by the contents of the variable *SysPrepOrder* in a way directly analogous to the ordering of *Boot####* options by *BootOrder*.

The platform is required to examine all *SysPrep####* variables referenced in *SysPrepOrder*. If Attributes bit *LOAD_OPTION_ACTIVE* is set, and the application referenced by *FilePathList[0]* is present, the UEFI Applications thus identified must be loaded and launched in the order they appear in SysPrepOrder and prior to the launch of any load options of type *Boot####*.

When launched, the platform is required to provide the application loaded by S *ysPrep####* , with the same services such as console and network as are normally provided at launch to applications referenced by a *Boot####* variable. *SysPrep####* application must exit and may not call *ExitBootServices()*. Processing of any Error Code returned at exit is according to system policy and does not necessarily change processing of following boot options. Any driver portion of the feature supported by *SysPrep####* boot option that is required to remain resident should be loaded by use of *Driver####* variable.

The Attributes option *LOAD_OPTION_FORCE_RECONNECT* is ignored for *SysPrep####* variables, and in the event that an application so launched performs some action that adds to the available hardware or drivers, the system preparation application shall itself utilize appropriate calls to *ConnectController()* or *DisconnectController()* to revise connections between drivers and hardware

After all *SysPrep####* variables have been launched and exited, the platform shall notify *EFI_EVENT_GROUP_READY_TO_BOOT* and EFI_EVENT_GROUP_AFTER_READY_TO_BOOT event groups. This should happen when the Boot Manager is about to load and execute *Boot####* variables with Attributes set to *LOAD_OPTION_CATEGORY_BOOT* according to the order defined by BootOrder.

3.2 Boot Manager Policy Protocol

3.2.1 EFI_BOOT_MANAGER_POLICY_PROTOCOL

Summary

This protocol is used by EFI Applications to request the UEFI Boot Manager to connect devices using platform policy.

GUID

```
#define EFI_BOOT_MANAGER_POLICY_PROTOCOL_GUID \
  { 0xFEDF8E0C, 0xE147, 0x11E3,\
  { 0x99, 0x03, 0xB8, 0xE8, 0x56, 0x2C, 0xBA, 0xFA } }
```

Protocol Interface Structure

```
typedef struct _EFI_BOOT_MANAGER_POLICY_PROTOCOL
  EFI_BOOT_MANAGER_POLICY_PROTOCOL;
struct \_EFI_BOOT_MANAGER_POLICY_PROTOCOL {
  UINT64                                        Revision;
EFI_BOOT_MANAGER_POLICY_CONNECT_DEVICE_PATH     ConnectDevicePath;
  EFI_BOOT_MANAGER_POLICY_CONNECT_DEVICE_CLASS  ConnectDeviceClass;
};
```

ConnectDevicePath
Connect a Device Path following the platforms EFI Boot Manager policy.

ConnectDeviceClass
Connect a class of devices, named by EFI_GUID, following the platforms UEFI Boot Manager policy.

Description

The EFI_BOOT_MANAGER_POLICY_PROTOCOL is produced by the platform firmware to expose Boot Manager policy and platform specific EFI_BOOT_SERVICES.ConnectController() *EFI_BOOT_SERVICES.ConnectController()* behavior.

Related Definitions

```
#define EFI_BOOT_MANAGER_POLICY_PROTOCOL_REVISION 0x00010000
```

3.2.2 EFI_BOOT_MANAGER_POLICY_PROTOCOL.ConnectDevicePath()

Summary

Connect a device path following the platform's EFI Boot Manager policy.

```
Prototype
typedef
EFI_STATUS
(EFIAPI *EFI_BOOT_MANAGER_POLICY_CONNECT_DEVICE_PATH)(
   IN EFI_BOOT_MANAGER_POLICY_PROTOCOL            *This,
   IN EFI_DEVICE_PATH                             *DevicePath,
   IN BOOLEAN                                     Recursive
   );
```

Parameters

This
A pointer to the EFI_BOOT_MANAGER_POLICY_PROTOCOL instance. Type EFI_BOOT_MANAGER_POLICY_PROTOCOL defined above.

DevicePath
Points to the start of the EFI device path to connect. If *DevicePath* is NULL then all the controllers in the system will be connected using the platform's EFI Boot Manager policy.

Recursive
If **TRUE**, then ConnectController() is called recursively until the entire tree of controllers below the controller specified by DevicePath have been created. If **FALSE**, then the tree of controllers is only expanded one level. If DevicePath is NULL then Recursive is ignored.

Description

The *ConnectDevicePath()* function allows the caller to connect a *DevicePath* using the same policy as the EFI Boot Manager.

If *Recursive* is **TRUE** , then *ConnectController()* is called recursively until the entire tree of controllers below the controller specified by *DevicePath* have been created. If *Recursive* is **FALSE**, then the tree of controllers is only expanded one level. If *DevicePath* is NULL then *Recursive* is ignored.

Status Codes Returned

EFI_SUCCESS	The *DevicePath* was connected
EFI_NOT_FOUND	The *DevicePath* was not found
EFI_NOT_FOUND	No driver was connected to *DevicePath*.
EFI_SECURITY_VIOLATION	The user has no permission to start UEFI device drivers
EFI_UNSUPPORTED	The current TPL is not *TPL_APPLICATION*.

3.2.3 EFI_BOOT_MANAGER_POLICY_PROTOCOL.ConnectDeviceClass()

Summary

Connect a class of devices using the platform Boot Manager policy.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_BOOT_MANAGER_POLICY_CONNECT_DEVICE_CLASS)(
   IN EFI_BOOT_MANAGER_POLICY_PROTOCOL          *This,
   IN EFI_GUID                                  *Class
   );
```

Parameters

This

A pointer to the EFI_BOOT_MANAGER_POLICY_PROTOCOL instance. Type EFI_BOOT_MANAGER_POLICY_PROTOCOL is defined above.

Class

A pointer to an *EFI_GUID* that represents a class of devices that will be connected using the Boot Manager's platform policy.

Description

The *ConnectDeviceClass()* function allows the caller to request that the Boot Manager connect a class of devices.

If *Class* is *EFI_BOOT_MANAGER_POLICY_CONSOLE_GUID* then the Boot Manager will use platform policy to connect consoles. Some platforms may restrict the number of consoles connected as they attempt to fast boot, and calling *ConnectDeviceClass()* with a *Class* value of *EFI_BOOT_MANAGER_POLICY_CONSOLE_GUID* must connect the set of consoles that follow the Boot Manager platform policy, and the *EFI_SIMPLE_TEXT_INPUT_PROTOCOL* , *EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL* , and the *EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL* are produced on the connected handles. The Boot Manager may restrict which consoles get connect due to platform policy, for example a security policy may require that a given console is not connected.

If *Class* is *EFI_BOOT_MANAGER_POLICY_NETWORK_GUID* then the Boot Manager will connect the protocols the platform supports for UEFI general purpose network applications on one or more handles. The protocols associated with UEFI general purpose network applications are defined in *Platform-Specific Elements* , list item number 7. If more than one network controller is available a platform will connect, one, many, or all of the networks based on platform policy. Connecting UEFI networking protocols, like *EFI_DHCP4_PROTOCOL* , does not establish connections on the network. The UEFI general purpose network application that called *ConnectDeviceClass()* may need to use the published protocols to establish the network connection. The Boot Manager can optionally have a policy to establish a network connection.

If *Class* is *EFI_BOOT_MANAGER_POLICY_CONNECT_ALL_GUID* then the Boot Manager will connect all UEFI drivers using the UEFI Boot Service *EFI_BOOT_SERVICES.ConnectController()*. If the Boot Manager has policy associated with connect all UEFI drivers this policy will be used.

A platform can also define platform specific *Class* values as a properly generated *EFI_GUID* would never conflict with this specification.

Related Definitions

```
#define EFI_BOOT_MANAGER_POLICY_CONSOLE_GUID \
   { 0xCAB0E94C, 0xE15F, 0x11E3,\
   { 0x91, 0x8D, 0xB8, 0xE8, 0x56, 0x2C, 0xBA, 0xFA } }
#define EFI_BOOT_MANAGER_POLICY_NETWORK_GUID \
   { 0xD04159DC, 0xE15F, 0x11E3,\
   { 0xB2, 0x61, 0xB8, 0xE8, 0x56, 0x2C, 0xBA, 0xFA } }
#define EFI_BOOT_MANAGER_POLICY_CONNECT_ALL_GUID \
   { 0x113B2126, 0xFC8A, 0x11E3,\
     { 0xBD, 0x6C, 0xB8, 0xE8, 0x56, 0x2C, 0xBA, 0xFA } }
```

Status Codes Returned

EFI_SUCCESS	At least one devices of the *Class* was connected.
EFI_DE ERROR	Devices were not connected due to an error.
EFI_NOT_FOUND	The *Class* is not supported by the platform.
EFI_UNSUPPORTED	The current TPL is not *TPL_APPLICATION*.

3.3 Globally Defined Variables

This section defines a set of variables that have architecturally defined meanings. In addition to the defined data content, each such variable has an architecturally defined attribute that indicates when the data variable may be accessed. The variables with an attribute of NV are nonvolatile. This means that their values are persistent across resets and power cycles. The value of any environment variable that does not have this attribute will be lost when power is removed from the system and the state of firmware reserved memory is not otherwise preserved. The variables with an attribute of BS are only available before *EFI_BOOT_SERVICES.ExitBootServices()* is called. This means that these environment variables can only be retrieved or modified in the preboot environment. They are not visible to an operating system. Environment variables with an attribute of RT are available before and after *ExitBootServices()* is called. Environment variables of this type can be retrieved and modified in the preboot environment, and from an operating system. The variables with an attribute of AT are variables with a time-based authenticated write access defined in *Using the EFI_VARIABLE_AUTHENTICATION_3 descriptor*. All architecturally defined variables use the *EFI_GLOBAL_VARIABLE VendorGuid*.

```
#define EFI_GLOBAL_VARIABLE \
 {0x8BE4DF61,0x93CA,0x11d2,\
   {0xAA,0x0D,0x00,0xE0,0x98,0x03,0x2B,0x8C}}
```

To prevent name collisions with possible future globally defined variables, other internal firmware data variables that are not defined here must be saved with a unique *VendorGuid* other than *EFI_GLOBAL_VARIABLE* or any other GUID defined by the UEFI Specification. Implementations must only permit the creation of variables with a UEFI Specification-defined *VendorGuid* when these variables are documented in the UEFI Specification.

Table 3.3: Global Variables

Variable Name	Attribute	Description
AuditMode	BS, RT	Whether the system is operating in Audit Mode (1) or not (0). All other values are reserved. Should be treated as read-only except when DeployedMode is 0. Always becomes read-only after ExitBootServices() is called.
Boot####	NV, BS, RT	A boot load option. #### is a printed hex value. No 0x or h is included in the hex value.
BootCurrent	BS, RT	The boot option that was selected for the current boot.
BootNext	NV, BS, RT	The boot option for the next boot only.
BootOrder	NV, BS, RT	The ordered boot option load list.
BootOptionSupport	BS,RT,	The types of boot options supported by the boot manager. Should be treated as read-only.
ConIn	NV, BS, RT	The device path of the default input console.
ConInDev	BS, RT	The device path of all possible console input devices.
ConOut	NV, BS, RT	The device path of the default output console.
ConOutDev	BS, RT	The device path of all possible console output devices.
dbDefault	BS, RT	The OEM's default secure boot signature store. Should be treated as read-only.
dbrDefault	BS, RT	The OEM's default OS Recovery signature store. Should be treated as read-only.
dbtDefault	BS, RT	The OEM's default secure boot timestamp signature store. Should be treated as read-only.
dbxDefault	BS, RT	The OEM's default secure boot blacklist signature store. Should be treated as read-only.
DeployedMode	BS, RT	Whether the system is operating in Deployed Mode (1) or not (0). All other values are reserved. Should be treated as read-only when its value is 1. Always becomes read-only after ExitBootServices() is called.
Driver####	NV, BS, RT	A driver load option. #### is a printed hex value.
DriverOrder	NV, BS, RT	The ordered driver load option list.
ErrOut	NV, BS, RT	The device path of the default error output device.
ErrOutDev	BS, RT	The device path of all possible error output devices.
HwErrRecSupport	NV, BS, RT	Identifies the level of hardware error record persistence support implemented by the platform. This variable is only modified by firmware and is read-only to the OS.
KEK	NV, BS, RT,AT	The Key Exchange Key Signature Database.
KEKDefault	BS, RT	The OEM's default Key Exchange Key Signature Database. Should be treated as read-only.
Key####	NV, BS, RT	Describes hot key relationship with a Boot#### load option.
Lang	NV, BS, RT	The language code that the system is configured for. This value is deprecated.
LangCodes	BS, RT	The language codes that the firmware supports. This value is deprecated.
OsIndications	NV, BS, RT	Allows the OS to request the firmware to enable certain features and to take certain actions.
OsIndicationsSupported	BS, RT	Allows the firmware to indicate supported features and actions to the OS.
OsRecoveryOrder	BS,RT,NV,AT	OS-specified recovery options.
PK	NV, BS, RT,AT	The public Platform Key.

continues on next page

Table 3.3 – continued from previous page

PKDefault	BS, RT	The OEM's default public Platform Key. Should be treated as read-only.
PlatformLangCodes	BS, RT	The language codes that the firmware supports.
PlatformLang	NV, BS, RT	The language code that the system is configured for.
PlatformRecovery####	BS, RT	Platform-specified recovery options. These variables are only modified by firmware and are read-only to the OS.
SignatureSupport	BS, RT	Array of GUIDs representing the type of signatures supported by the platform firmware. Should be treated as read-only.
SecureBoot	BS, RT	Whether the platform firmware is operating in Secure boot mode (1) or not (0). All other values are reserved. Should be treated as read-only.
SetupMode	BS, RT	Whether the system should require authentication on SetVariable() requests to Secure Boot policy variables (0) or not (1). Should be treated as read-only. The system is in "Setup Mode" when SetupMode==1, AuditMode==0, and DeployedMode==0.
SysPrep####	NV, BS, RT	A System Prep application load option containing an *EFI_LOAD_OPTION* descriptor. #### is a printed hex value.
SysPrepOrder	NV, BS, RT	The ordered System Prep Application load option list.
Timeout	NV, BS, RT	The firmware's boot managers timeout, in seconds, before initiating the default boot selection.
VendorKeys	BS, RT	Whether the system is configured to use only vendor-provided keys or not. Should be treated as read-only.

The *PlatformLangCodes* variable contains a null- terminated ASCII string representing the language codes that the firmware can support. At initialization time the firmware computes the supported languages and creates this data variable. Since the firmware creates this value on each initialization, its contents are not stored in nonvolatile memory. This value is considered read-only. *PlatformLangCodes* is specified in Native RFC 4646 format. *Appendix M — Formats — Language Codes and Language Code Arrays*. *LangCodes* is deprecated and may be provided for backwards compatibility.

The *PlatformLang* variable contains a null- terminated ASCII string language code that the machine has been configured for. This value may be changed to any value supported by *PlatformLangCodes*. If this change is made in the preboot environment, then the change will take effect immediately. If this change is made at OS runtime, then the change does not take effect until the next boot. If the language code is set to an unsupported value, the firmware will choose a supported default at initialization and set *PlatformLang* to a supported value. *PlatformLang* is specified in Native RFC 4646 array format. *Appendix M — Formats — Language Codes and Language Code Arrays* . *Lang* is deprecated and may be provided for backwards compatibility.

Lang has been deprecated. If the platform supports this variable, it must map any changes in the *Lang* variable into *PlatformLang* in the appropriate format.

Langcodes has been deprecated. If the platform supports this variable, it must map any changes in the *Langcodes* variable into *PlatformLang* in the appropriate format.

The *Timeout* variable contains a binary *UINT16* that supplies the number of seconds that the firmware will wait before initiating the original default boot selection. A value of 0 indicates that the default boot selection is to be initiated immediately on boot. If the value is not present, or contains the value of 0xFFFF then firmware will wait for user input before booting. This means the default boot selection is not automatically started by the firmware.

The *ConIn* , *ConOut* , and *ErrOut* variables each contain an *EFI Device Path Protocol* descriptor that defines the default device to use on boot. Changes to these values made in the preboot environment take effect immediately. Changes to these values at OS runtime do not take effect until the next boot. If the firmware cannot resolve the device path, it is allowed to automatically replace the values, as needed, to provide a console for the system. If the device path starts with a USB Class device path (*USB Class Device Path*), then any input or output device that matches the device path must be used as a console if it is supported by the firmware.

The *ConInDev* , *ConOutDev* , and *ErrOutDev* variables each contain an *EFI_DEVICE_PATH_PROTOCOL* descriptor that defines all the possible default devices to use on boot. These variables are volatile, and are set dynamically on every boot. *ConIn* , *ConOut* , and *ErrOut* are always proper subsets of *ConInDev* , *ConOutDev* , and *ErrOutDev* .

Each *Boot####* variable contains an *EFI_LOAD_OPTION*. Each *Boot####* variable is the name "Boot" appended with a unique four digit hexadecimal number. For example, Boot0001, Boot0002, Boot0A02, etc.

The *OsRecoveryOrder* variable contains an array of *EFI_GUID* structures. Each *EFI_GUID* structure specifies a namespace for variables containing OS-defined recovery entries (See *OS-Defined Boot Option Recovery*). Write access to this variable is controlled by the security key database dbr (*Using the EFI_VARIABLE_AUTHENTICATION_3 descriptor*).

PlatformRecovery#### variables share the same structure as Boot#### variables. These variables are processed when the system is performing recovery of boot options.

The *BootOrder* variable contains an array of *UINT16* 's that make up an ordered list of the *Boot####* options. The first element in the array is the value for the first logical boot option, the second element is the value for the second logical boot option, etc. The *BootOrder* order list is used by the firmware's boot manager as the default boot order.

The *BootNext* variable is a single *UINT16* that defines the *Boot####* option that is to be tried first on the next boot. After the *BootNext* boot option is tried the normal *BootOrder* list is used. To prevent loops, the boot manager deletes this variable before transferring control to the preselected boot option.

The *BootCurrent* variable is a single *UINT16* that defines the *Boot####* option that was selected on the current boot. The platform sets this variable before signaling EFI_EVENT_GROUP_READY_TO_BOOT. This variable is not set when attempting to launch OsRecovery### or PlatformRecovery### options.

The *BootOptionSupport* variable is a *UINT32* that defines the types of boot options supported by the boot manager.

Each *Driver####* variable contains an *EFI_LOAD_OPTION*. Each load option variable is appended with a unique number, for example Driver0001, Driver0002, etc.

The *DriverOrder* variable contains an array of *UINT16* 's that make up an ordered list of the *Driver####* variable. The first element in the array is the value for the first logical driver load option, the second element is the value for the second logical driver load option, etc. The *DriverOrder* list is used by the firmware's boot manager as the default load order for UEFI drivers that it should explicitly load.

The *Key####* variable associates a key press with a single boot option. Each *Key####* variable is the name "Key" appended with a unique four digit hexadecimal number. For example, Key0001, Key0002, Key00A0, etc.

The *HwErrRecSupport* variable contains a binary UINT16 that supplies the level of support for Hardware Error Record Persistence (*Hardware Error Record Persistence*) that is implemented by the platform. If the value is not present, then the platform implements no support for Hardware Error Record Persistence. A value of zero indicates that the platform implements no support for Hardware Error Record Persistence. A value of 1 indicates that the platform implements Hardware Error Record Persistence as defined in *Hardware Error Record Persistence*. Firmware initializes this variable. All other values are reserved for future use.

The *SetupMode* variable is an 8-bit unsigned integer that defines whether the system is should require authentication (0) or not (1) on *SetVariable()* requests to Secure Boot Policy Variables. Secure Boot Policy Variables include:

- The global variables *PK* , *KEK* , and *OsRecoveryOrder*
- All variables named *OsRecovery####* under all VendorGuids
- All variables with the VendorGuid *EFI_IMAGE_SECURITY_DATABASE_GUID.*

Secure Boot Policy Variables must be created using the *EFI_VARIABLE_AUTHENTICATION_2* structure.

The *AuditMode* variable is an 8-bit unsigned integer that defines whether the system is currently operating in Audit Mode.

The *DeployedMode* variable is an 8-bit unsigned integer that defines whether the system is currently operating in Deployed Mode.

The *KEK* variable contains the current Key Exchange Key database.

The *PK* variable contains the current Platform Key.

The *VendorKeys* variable is an 8-bit unsigned integer that defines whether the Security Boot Policy Variables have been modified by anyone other than the platform vendor or a holder of the vendor-provided keys. A value of 0 indicates that someone other than the platform vendor or a holder of the vendor-provided keys has modified the Secure Boot Policy Variables Otherwise, the value will be 1.

The *KEKDefault* variable, if present, contains the platform-defined Key Exchange Key database. This is not used at runtime but is provided in order to allow the OS to recover the OEM's default key setup. The contents of this variable do not include an *EFI_VARIABLE_AUTHENTICATION* or *EFI_VARIABLE_AUTHENTICATION2* structure.

The *PKDefault* variable, if present, contains the platform-defined Platform Key. This is not used at runtime but is provided in order to allow the OS to recover the OEM's default key setup. The contents of this variable do not include an *EFI_VARIABLE_AUTHENTICATION2* structure.

The *dbDefault* variable, if present, contains the platform-defined secure boot signature database. This is not used at runtime but is provided in order to allow the OS to recover the OEM's default key setup. The contents of this variable do not include an *EFI_VARIABLE_AUTHENTICATION2* structure.

The *dbrDefault* variable, if present, contains the platform-defined secure boot authorized recovery signature database. This is not used at runtime but is provided in order to allow the OS to recover the OEM's default key setup. The contents of this variable do not include an *EFI_VARIABLE_AUTHENTICATION2* structure.

The *dbtDefault* variable, if present, contains the platform-defined secure boot timestamp signature database. This is not used at runtime but is provided in order to allow the OS to recover the OEM's default key setup. The contents of this variable do not include an *EFI_VARIABLE_AUTHENTICATION2* structure.

The *dbxDefault* variable, if present, contains the platform-defined secure boot blacklist signature database. This is not used at runtime but is provided in order to allow the OS to recover the OEM's default key setup. The contents of this variable do not include an *EFI_VARIABLE_AUTHENTICATION2* structure.

The *SignatureSupport* variable returns an array of GUIDs, with each GUID representing a type of signature which the platform firmware supports for images and other data. The different signature types are described in "Signature Database".

The *SecureBoot* variable is an 8-bit unsigned integer that defines whether the platform firmware is operating with Secure Boot enabled. A value of 1 indicates that platform firmware performs driver and boot application signature verification as specified in *UEFI Image Validation* during the current boot. A value of 0 indicates that driver and boot application signature verification is not active during the current boot. The SecureBoot variable is initialized prior to Secure Boot image authentication and thereafter should be treated as read-only and immutable. Its initialization value is determined by platform policy but must be 0 if the platform is in Setup Mode or Audit Mode during its initialization.

The *OsIndicationsSupported* variable indicates which of the OS indication features and actions that the firmware supports. This variable is recreated by firmware every boot, and cannot be modified by the OS (see *SetVariable()* Attributes usage rules once *ExitBootServices()* is performed).

The *OsIndications* variable is used to indicate which features the OS wants firmware to enable or which actions the OS wants the firmware to take. The OS will supply this data with a *SetVariable()* call. *Exchanging information between the OS and Firmware* for the variable definition.

3.4 Boot Option Recovery

Boot option recovery consists of two independent parts, operating system-defined recovery and platform-defined recovery. OS-defined recovery is an attempt to allow installed operating systems to recover any needed boot options, or to launch full operating system recovery. Platform-defined recovery includes any remedial actions performed by the platform as a last resort when no operating system is found, such as the Default Boot Behavior (*Boot Option Variables Default Boot Behavior*). This could include behaviors such as warranty service reconfiguration or diagnostic options.

In the event that boot option recovery must be performed, the boot manager must first attempt OS-defined recovery, re-attempt normal booting via *Boot####* and *BootOrder* variables, and finally attempt platform-defined recovery if no options have succeeded.

3.4.1 OS-Defined Boot Option Recovery

If the *EFI_OS_INDICATIONS_START_OS_RECOVERY* bit is set in *OsIndications* , or if processing of *BootOrder* does not result in success, the platform must process OS-defined recovery options. In the case where OS-defined recovery is entered due to *OsIndications* , *SysPrepOrder* and *SysPrep####* variables should not be processed. Note that in order to avoid ambiguity in intent, this bit is ignored in *OsIndications* if *EFI_OS_INDICATIONS_START_PLATFORM_RECOVERY* is set.

OS-defined recovery uses the *OsRecoveryOrder* variable, as well as variables created with vendor specific *VendorGuid* values and a name following the pattern *OsRecovery####*. Each of these variables must be an authenticated variable with the *EFI_VARIABLE_TIME_BASED_AUTHENTICATED_WRITE_ACCESS* attribute set.

To process these variables, the boot manager iterates over the array of EFI_GUID structures in the *OsRecoveryOrder* variable, and each GUID specified is treated as a *VendorGuid* associated with a series of variable names. For each GUID, the firmware attempts to load and execute, in hexadecimal sort order, every variable with that GUID and a name following the pattern *OsRecovery####*. These variables have the same format as *Boot####* variables, and the boot manager must verify that each variable it attempts to load was created with a public key that is associated with a certificate chaining to one listed in the authorized recovery signature database *dbr* and not in the forbidden signature database, or is created by a key in the Key Exchange Key database *KEK* or the current Platform Key *PK* .

If the boot manager finishes processing *OsRecovery####* options without *EFI_BOOT_SERVICES.ExitBootServices()* or *ResetSystem()* having been called, it must attempt to process *BootOrder* a second time. If booting does not succeed during that process, OS-defined recovery has failed, and the boot manager must attempt platform-based recovery.

If, while processing *OsRecovery####* variables, the boot manager encounters an entry which cannot be loaded or executed due to a security policy violation, it must ignore that variable.

3.4.2 Platform-Defined Boot Option Recovery

If the *EFI_OS_INDICATIONS_START_PLATFORM_RECOVERY* bit is set in *OsIndications* , or if OS-defined recovery has failed, the system firmware must commence with platform-specific recovery by iterating its *PlatformRecovery####* variables in the same manner as *OsRecovery####* , but must stop processing if any entry is successful. In the case where platform-specific recovery is entered due to *OsIndications* , *SysPrepOrder* and *SysPrep####* variables should not be processed.

3.4.3 Boot Option Variables Default Boot Behavior

The default state of globally-defined variables is firmware vendor specific. However the boot options require a standard default behavior in the exceptional case that valid boot options are not present on a platform. The default behavior must be invoked any time the *BootOrder* variable does not exist or only points to nonexistent boot options, or if no entry in *BootOrder* can successfully be executed.

If system firmware supports boot option recovery as described in *Boot Option Recovery* , system firmware must include a *PlatformRecovery####* variable specifying a short-form File Path Media Device Path (*Load Option Processing*) containing the platform default file path for removable media (*UEFI Image Types*). It is recommended for maximal compatibility with prior versions of this specification that this entry be the first such variable, though it may be at any position within the list.

It is expected that this default boot will load an operating system or a maintenance utility. If this is an operating system setup program it is then responsible for setting the requisite environment variables for subsequent boots. The platform firmware may also decide to recover or set to a known set of boot options.

3.5 Boot Mechanisms

EFI can boot from a device using the *EFI_SIMPLE_FILE_SYSTEM_PROTOCOL* or the *EFI_LOAD_FILE_PROTOCOL*. A device that supports the *EFI_SIMPLE_FILE_SYSTEM_PROTOCOL* must materialize a file system protocol for that device to be bootable. If a device does not wish to support a complete file system it may produce an *EFI_LOAD_FILE_PROTOCOL* which allows it to materialize an image directly. The Boot Manager will attempt to boot using the *EFI_SIMPLE_FILE_SYSTEM_PROTOCOL* first. If that fails, then the *EFI_LOAD_FILE_PROTOCOL* will be used.

3.5.1 Boot via the Simple File Protocol

When booting via the *EFI_SIMPLE_FILE_SYSTEM_PROTOCOL* , the *FilePath* will start with a device path that points to the device that implements the *EFI_SIMPLE_FILE_SYSTEM_PROTOCOL* or the *EFI_BLOCK_IO_PROTOCOL*. The next part of the *FilePath* may point to the file name, including subdirectories, which contain the bootable image. If the file name is a null device path, the file name must be generated from the rules defined below.

If the *FilePathList[0]* device does not support the *EFI_SIMPLE_FILE_SYSTEM_PROTOCOL* , but supports the *EFI_BLOCK_IO_PROTOCOL* protocol, then the EFI Boot Service *EFI_BOOT_SERVICES.ConnectController()* must be called for *FilePathList[0]* with *DriverImageHandle* and *RemainingDevicePath* set to *NULL* and the *Recursive* flag is set to *TRUE*.The firmware will then attempt to boot from any child handles produced using the algorithms outlined below.

The format of the file system specified is contained in *File System Format*. While the firmware must produce an *EFI_SIMPLE_FILE_SYSTEM_PROTOCOL* that understands the UEFI file system, any file system can be abstracted with the *EFI_SIMPLE_FILE_SYSTEM_PROTOCOL* interface.

3.5.1.1 Removable Media Boot Behavior

To generate a file name when none is present in the *FilePath* , the firmware must append a default file name in the form *EFIBOOTBOOT{machine type short-name}.EFI* where machine type short-name defines a PE32+ image format architecture. Each file only contains one UEFI image type, and a system may support booting from one or more images types. *UEFI Image Types* lists the UEFI image types.

Table 3.4: UEFI Image Types

	File Name Convention	**PE Executable Machine Type ***
32-bit	BOOTIA32.EFI	0x14c
x64	BOOTx64.EFI	0x8664
Itanium architecture	BOOTIA64.EFI	0x200
AArch32 architecture	BOOTARM.EFI	0x01c2
AArch64 architecture	BOOTAA64.EFI	0xAA64
RISC-V 32-bit architecture	BOOTRISCV32.EFI	0x5032
RISC-V 64-bit architecture	BOOTRISCV64.EFI	0x5064
RISC-V 128-bit architecture	BOOTRISCV128.EFI	0x5128

Note: *The PE Executable machine type is contained in the machine field of the COFF file header as defined in the Microsoft Portable Executable and Common Object File Format Specification, Revision 6.0*

Media may support multiple architectures by simply having a \EFIBOOTBOOT{machine type short-name}.EFI file of each possible machine type.

3.5.2 Boot via the Load File Protocol

When booting via the *EFI_LOAD_FILE_PROTOCOL* protocol, the *FilePath* is a device path that points to a device that "speaks" the *EFI_LOAD_FILE_PROTOCOL*. The image is loaded directly from the device that supports the *EFI_LOAD_FILE_PROTOCOL*. The remainder of the *FilePath* will contain information that is specific to the device. Firmware passes this device-specific data to the loaded image, but does not use it to load the image. If the remainder of the *FilePath* is a null device path it is the loaded image's responsibility to implement a policy to find the correct boot device.

The *EFI_LOAD_FILE_PROTOCOL* is used for devices that do not directly support file systems. Network devices commonly boot in this model where the image is materialized without the need of a file system.

3.5.2.1 Network Booting

Network booting is described by the *Preboot eXecution Environment (PXE) BIOS Support Specification*. PXE specifies UDP, DHCP, and TFTP network protocols that a booting platform can use to interact with an intelligent system load server. UEFI defines special interfaces that are used to implement PXE. These interfaces are contained in the *EFI_PXE_BASE_CODE_PROTOCOL* .

3.5.2.2 Future Boot Media

Since UEFI defines an abstraction between the platform and the OS and its loader it should be possible to add new types of boot media as technology evolves. The OS loader will not necessarily have to change to support new types of boot. The implementation of the UEFI platform services may change, but the interface will remain constant. The OS will require a driver to support the new type of boot media so that it can make the transition from UEFI boot services to OS control of the boot media.

CHAPTER

FOUR

EFI SYSTEM TABLE

This section describes the entry point to a UEFI image and the parameters that are passed to that entry point. There are three types of UEFI images that can be loaded and executed by firmware conforming to this specification. These are UEFI applications (*UEFI Applications*), UEFI boot service drivers (*UEFI Drivers*), and UEFI runtime drivers (*UEFI Drivers*). UEFI applications include UEFI OS loaders (*UEFI OS Loaders*). There are no differences in the entry point for these three image types.

4.1 UEFI Image Entry Point

The most significant parameter that is passed to an image is a pointer to the System Table (see definition immediately below), the main entry point for a UEFI Image. The System Table contains pointers to the active console devices, a pointer to the Boot Services Table, a pointer to the Runtime Services Table, and a pointer to the list of system configuration tables such as ACPI, SMBIOS, and the SAL System Table. This section describes the System Table in detail.

4.1.1 EFI_IMAGE_ENTRY_POINT

Summary

This is the main entry point for a UEFI Image. This entry point is the same for UEFI applications and UEFI drivers.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_IMAGE_ENTRY_POINT) (
  IN EFI_HANDLE                  ImageHandle,
  IN EFI_SYSTEM_TABLE            *SystemTable
  );
```

Parameters

ImageHandle
The firmware allocated handle for the UEFI image.

SystemTable
A pointer to the EFI System Table.

Description

This function is the entry point to an EFI image. An EFI image is loaded and relocated in system memory by the EFI Boot Service *EFI_BOOT_SERVICES.LoadImage()* . An EFI image is invoked through the EFI Boot Service *EFI_BOOT_SERVICES.StartImage()*.

The first argument is the image's image handle. The second argument is a pointer to the image's system table. The system table contains the standard output and input handles, plus pointers to the *EFI_BOOT_SERVICES* and *EFI_RUNTIME_SERVICES* tables. The service tables contain the entry points in the firmware for accessing the core EFI system functionality. The handles in the system table are used to obtain basic access to the console. In addition, the System Table contains pointers to other standard tables that a loaded image may use if the associated pointers are initialized to nonzero values. Examples of such tables are ACPI, SMBIOS, SAL System Table, etc.

The *ImageHandle* is a firmware-allocated handle that is used to identify the image on various functions. The handle also supports one or more protocols that the image can use. All images support the *EFI_LOADED_IMAGE_PROTOCOL* and the *EFI_LOADED_IMAGE_DEVICE_PATH_PROTOCOL* that returns the source location of the image, the memory location of the image, the load options for the image, etc. The exact *EFI_LOADED_IMAGE_PROTOCOL* and *EFI_LOADED_IMAGE_DEVICE_PATH_PROTOCOL* structures are defined in *EFI_LOADED_IMAGE_PROTOCOL.Unload()* .

If the UEFI image is a UEFI application that is not a UEFI OS loader, then the application executes and either returns or calls the EFI Boot Services *EFI_BOOT_SERVICES.Exit()* . A UEFI application is always unloaded from memory when it exits, and its return status is returned to the component that started the UEFI application.

If the UEFI image is a UEFI OS Loader, then the UEFI OS Loader executes and either returns, calls the EFI Boot Service *Exit()* , or calls the EFI Boot Service *EFI_BOOT_SERVICES.ExitBootServices()* . If the EFI OS Loader returns or calls *Exit()* , then the load of the OS has failed, and the EFI OS Loader is unloaded from memory and control is returned to the component that attempted to boot the UEFI OS Loader. If *ExitBootServices()* is called, then the UEFI OS Loader has taken control of the platform, and EFI will not regain control of the system until the platform is reset. One method of resetting the platform is through the EFI Runtime Service *ResetSystem()* .

If the UEFI image is a UEFI Driver, then the UEFI driver executes and either returns or calls the Boot Service *Exit()* . If the UEFI driver returns an error, then the driver is unloaded from memory. If the UEFI driver returns *EFI_SUCCESS* , then it stays resident in memory. If the UEFI driver does not follow the UEFI Driver Model, then it performs any required initialization and installs its protocol services before returning. If the driver does follow the UEFI Driver Model, then the entry point is not allowed to touch any device hardware. Instead, the entry point is required to create and install the *EFI Driver Binding Protocol* (*EFI Driver Binding Protocol*) on the *ImageHandle* of the UEFI driver. If this process is completed, then *EFI_SUCCESS* is returned. If the resources are not available to complete the UEFI driver initialization, then *EFI_OUT_OF_RESOURCES* is returned.

Status Codes Returned

EFI_SUCCESS	The driver was initialized.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.

4.2 EFI Table Header

The data type *EFI_TABLE_HEADER* is the data structure that precedes all of the standard EFI table types. It includes a signature that is unique for each table type, a revision of the table that may be updated as extensions are added to the EFI table types, and a 32-bit CRC so a consumer of an EFI table type can validate the contents of the EFI table.

4.2.1 EFI_TABLE_HEADER

Summary

Data structure that precedes all of the standard EFI table types.

Related Definitions

```
typedef struct {
  UINT64      Signature;
  UINT32      Revision;
  UINT32      HeaderSize;
  UINT32      CRC32;
  UINT32      Reserved;
 } EFI_TABLE_HEADER;
```

Parameters

Signature
A 64-bit signature that identifies the type of table that follows. Unique signatures have been generated for the EFI System Table, the EFI Boot Services Table, and the EFI Runtime Services Table.

Revision
The revision of the EFI Specification to which this table conforms. The upper 16 bits of this field contain the major revision value, and the lower 16 bits contain the minor revision value. The minor revision values are binary coded decimals and are limited to the range of 00..99.

When printed or displayed UEFI spec revision is referred as (Major revision).(Minor revision upper decimal).(Minor revision lower decimal) or (Major revision).(Minor revision upper decimal) in case Minor revision lower decimal is set to 0. For example:

Specification with the revision value ((2<<16) | (30)) would be referred as 2.3;

A specification with the revision value ((2<<16) | (31)) would be referred as 2.3.1

HeaderSize
The size, in bytes, of the entire table including the FI_TABLE_HEADER.

CRC32
The 32-bit CRC for the entire table. This value is computed by setting this field to 0, and computing the 32-bit CRC for HeaderSize bytes.

Reserved
Reserved field that must be set to 0.

NOTE: The capabilities found in the EFI system table, runtime table and boot services table may change over time. The first field in each of these tables is an EFI_TABLE_HEADER. This header's Revision field is incremented when new capabilities and functions are added to the functions in the table. When checking for capabilities, code should verify that Revision is greater than or equal to the revision level of the table at the point when the capabilities were added to the UEFI specification.

NOTE: Unless otherwise specified, UEFI uses a standard CCITT32 CRC algorithm with a seed polynomial value of 0x04c11db7 for its CRC calculations.

NOTE: The size of the system table, runtime services table, and boot services table may increase over time. It is very important to always use the HeaderSize field of the EFI_TABLE_HEADER to determine the size of these tables.

4.3 EFI System Table

UEFI uses the EFI System Table, which contains pointers to the runtime and boot services tables. The definition for this table is shown in the following code fragments. Except for the table header, all elements in the service tables are pointers to functions as defined in *Services — Boot Services* and *Services — Runtime Services* . Prior to a call to *EFI_BOOT_SERVICES.ExitBootServices()* , all of the fields of the EFI System Table are valid. After an operating system has taken control of the platform with a call to *ExitBootServices()* , only the *Hdr* , *FirmwareVendor* , *FirmwareRevision* , *RuntimeServices* , *NumberOfTableEntries* , and *ConfigurationTable* fields are valid.

4.3.1 EFI_SYSTEM_TABLE

Summary

Contains pointers to the runtime and boot services tables.

  UINTN                            NumberOfTableEntries;
  EFI_CONFIGURATION_TABLE          *ConfigurationTable;
} EFI_SYSTEM_TABLE;
```

Parameters

Hdr

The table header for the EFI System Table. This header contains the EFI_SYSTEM_TABLE_SIGNATURE and

EFI_SYSTEM_TABLE_REVISION values along with the size of the EFI_SYSTEM_TABLE structure and a 32-bit CRC to verify that the contents of the EFI System Table are valid.

FirmwareVendor
A pointer to a null terminated string that identifies the vendor that produces the system firmware for the platform.

FirmwareRevision
A firmware vendor specific value that identifies the revision of the system firmware for the platform.

ConsoleInHandle
The handle for the active console input device. This handle must support EFI_SIMPLE_TEXT_INPUT_PROTOCOL and EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL . If there is no active console, these protocols must still be present.

ConIn
A pointer to the EFI_SIMPLE_TEXT_INPUT_PROTOCOL interface that is associated with *ConsoleInHandle*.

ConsoleOutHandle
The handle for the active console output device. This handle must support the *EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL*.

If there is no active console, this protocol must still be present.

ConOut
A pointer to the EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL interface that is associated with *ConsoleOutHandle*.

StandardErrorHandle
The handle for the active standard error console device. This handle must support the EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL. If there is no active console, this protocol must still be present.

StdErr
A pointer to the EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL interface that is associated with *StandardErrorHandle*.

RuntimeServices
A pointer to the *EFI Runtime Services Table*.

BootServices
A pointer to the EFI Boot Services Table. See ref:*efi-boot-services-table_efi_system_table*.

NumberOfTableEntries
The number of system configuration tables in the buffer *ConfigurationTable*.

ConfigurationTable
A pointer to the system configuration tables. The number of entries in the table is *NumberOfTableEntries*.

4.4 EFI Boot Services Table

UEFI uses the EFI Boot Services Table, which contains a table header and pointers to all of the boot services. The definition for this table is shown in the following code fragments. Except for the table header, all elements in the EFI Boot Services Tables are prototypes of function pointers to functions as defined in *Services — Boot Services* . The function pointers in this table are not valid after the operating system has taken control of the platform with a call to *EFI_BOOT_SERVICES.ExitBootServices()* .

4.4.1 EFI_BOOT_SERVICES

Summary

Contains a table header and pointers to all of the boot services.

   EFI_CREATE_EVENT_EX    CreateEventEx;  // UEFI 2.0+
 } EFI_BOOT_SERVICES;
```

Parameters

Hdr
The table header for the EFI Boot Services Table. This header contains the EFI_BOOT_SERVICES_SIGNATURE and EFI_BOOT_SERVICES_REVISION values along with the size of the EFI_BOOT_SERVICES structure and a 32-bit CRC to verify that the contents of the EFI Boot Services Table are valid.

RaiseTPL
Raises the task priority level.

RestoreTPL
Restores/lowers the task priority level.

AllocatePages
Allocates pages of a particular type.

FreePages
Frees allocated pages.

GetMemoryMap
Returns the current boot services memory map and memory map key.

AllocatePool
Allocates a pool of a particular type.

FreePool
Frees allocated pool.

CreateEvent
Creates a general-purpose event structure.

SetTimer
Sets an event to be signaled at a particular time.

WaitForEvent
Stops execution until an event is signaled.

SignalEvent
Signals an event.

CloseEvent
Closes and frees an event structure.

CheckEvent
Checks whether an event is in the signaled state.

InstallProtocolInterface
Installs a protocol interface on a device handle.

ReinstallProtocolInterface
Reinstalls a protocol interface on a device handle.

UninstallProtocolInterface
Removes a protocol interface from a device handle.

HandleProtocol
Queries a handle to determine if it supports a specified protocol.

Reserved
Reserved. Must be NULL.

RegisterProtocolNotify
Registers an event that is to be signaled whenever an interface is installed for a specified protocol.

LocateHandle
Returns an array of handles that support a specified protocol.

LocateDevicePath
Locates all devices on a device path that support a specified protocol and returns the handle to the device that is closest to the path.

InstallConfigurationTable
Adds, updates, or removes a configuration table from the EFI System Table.

LoadImag
Loads an EFI image into memory.

StartImage
Transfers control to a loaded image's entry point.

Exit
Exits the image's entry point.

UnloadImage
Unloads an image.

ExitBootServices
Terminates boot services.

GetNextMonotonicCount
Returns a monotonically increasing count for the platform.

Stall
Stalls the processor.

SetWatchdogTimer
Resets and sets a watchdog timer used during boot services time.

ConnectController
Uses a set of precedence rules to find the best set of drivers to manage a controller.

DisconnectController
Informs a set of drivers to stop managing a controller.

OpenProtocol
Adds elements to the list of agents consuming a protocol interface.

CloseProtocol
Removes elements from the list of agents consuming a protocol interface.

OpenProtocolInformtion
Retrieve the list of agents that are currently consuming a protocol interface.

ProtocolsPerHandle
Retrieves the list of protocols installed on a handle. The return buffer is automatically allocated.

LocateHandleBuffer
Retrieves the list of handles from the handle database that meet the search criteria. The return buffer is automatically allocated.

LocateProtocol
Finds the first handle in the handle database the supports the requested protocol.

InstallMultipleProtocolInterfaces
Installs one or more protocol interfaces onto a handle.

UninstallMultipleProtocolInterfaces
Uninstalls one or more protocol interfaces from a handle.

CalculateCrc32
Computes and returns a 32-bit CRC for a data buffer.

CopyMem
Copies the contents of one buffer to another buffer.

SetMem
Fills a buffer with a specified value.

CreateEventEx
Creates an event structure as part of an event group.

4.5 EFI Runtime Services Table

UEFI uses the EFI Runtime Services Table, which contains a table header and pointers to all of the runtime services. The definition for this table is shown in the following code fragments. Except for the table header, all elements in the EFI Runtime Services Tables are prototypes of function pointers to functions as defined in *Services — Runtime Services* . Unlike the EFI Boot Services Table, this table, and the function pointers it contains are valid after the UEFI OS loader and OS have taken control of the platform with a call to *EFI_BOOT_SERVICES.ExitBootServices()*. If a call to *SetVirtualAddressMap()* is made by the OS, then the function pointers in this table are fixed up to point to the new virtually mapped entry points.

4.5.1 EFI_RUNTIME_SERVICES

Summary

Contains a table header and pointers to all of the runtime services.

Related Definitions

```
#define EFI_RUNTIME_SERVICES_SIGNATURE 0x56524553544e5552
#define EFI_RUNTIME_SERVICES_REVISION EFI_SPECIFICATION_VERSION

   EFI_QUERY_CAPSULE_CAPABILITIES   QueryCapsuleCapabilities;

 //
 // Miscellaneous UEFI 2.0 Service
 //
  EFI_QUERY_VARIABLE_INFO          QueryVariableInfo;
} EFI_RUNTIME_SERVICES;
```

Parameters

Hdr
: The table header for the EFI Runtime Services Table. This header contains the EFI_RUNTIME_SERVICES_SIGNATURE and EFI_RUNTIME_SERVICES_REVISION values along with the size of the EFI_RUNTIME_SERVICES structure and a 32-bit CRC to verify that the contents of the EFI Runtime Services Table are valid.

GetTime
: Returns the current time and date, and the time-keeping capabilities of the platform.

SetTime
: Sets the current local time and date information.

GetWakeupTime
: Returns the current wakeup alarm clock setting.

SetWakeupTime
: Sets the system wakeup alarm clock time.

SetVirtualAddressMap
: Used by a UEFI OS loader to convert from physical addressing to virtual addressing.

ConvertPointer
: Used by EFI components to convert internal pointers when switching to virtual addressing.

GetVariable
: Returns the value of a variable.

GetNextVariableName
: Enumerates the current variable names.

SetVariable
: Sets the value of a variable.

GetNextHighMonotonicCount
Returns the next high 32 bits of the platform's monotonic counter.

ResetSyste
Resets the entire platform.

UpdateCapsule
Passes capsules to the firmware with both virtual and physical mapping.

QueryCapsuleCapabilities
nReturns if the capsule can be supported via UpdateCapsule() .

QueryVariableInfo
Returns information about the EFI variable store.

4.6 EFI Configuration Table & Properties Table

The EFI Configuration Table is the *ConfigurationTable* field in the EFI System Table. This table contains a set of GUID/pointer pairs. Each element of this table is described by the *EFI_CONFIGURATION_TABLE* structure below. The number of types of configuration tables is expected to grow over time. This is why a GUID is used to identify the configuration table type. The EFI Configuration Table may contain at most once instance of each table type.

4.6.1 EFI_CONFIGURATION_TABLE

Summary

Contains a set of GUID/pointer pairs comprised of *ConfigurationTable* field in the EFI System Table.

Related Definitions

```
typedef struct{
  EFI_GUID           VendorGuid;
  VOID               *VendorTable;
}   EFI_CONFIGURATION_TABLE;
```

Parameters

VendorGuid
The 128-bit GUID value that uniquely identifies the system configuration table.

VendorTable
A pointer to the table associated with VendorGuid. Type of the memory that is used to store the table as well as whether this pointer is a physical address or a virtual address during runtime (whether or not a particular address reported in the table gets fixed up when a call to SetVirtualAddressMap() is made) is determined by the VendorGuid. Unless otherwise specified, memory type of the table buffer is defined by the guidelines set forth in the Calling Conventions section in Chapter 2. It is the responsibility of the specification defining the VendorTable to specify additional memory type requirements (if any) and whether to convert the addresses reported in the table. Any required address conversion is a responsibility of the driver that publishes corresponding configuration table.

A pointer to the table associated with VendorGuid. Whether this pointer is a physical address or a virtual address during runtime is determined by the VendorGuid. The VendorGuid associated with a given VendorTable pointer defines whether or not a particular address reported in the table gets fixed up when a call to *SetVirtualAddressMap()* is made. It is the responsibility of the specification defining the VendorTable to specify whether to convert the addresses reported in the table.

4.6.1.1 Industry Standard Configuration Tables

The following list shows the GUIDs for tables defined in some of the industry standards. These industry standards define tables accessed as UEFI Configuration Tables on UEFI-based systems. All the addresses reported in these table entries will be referenced as physical and will not be fixed up when transition from preboot to runtime phase. This list is not exhaustive and does not show GUIDs for all possible UEFI Configuration tables.

```
#define EFI_ACPI_20_TABLE_GUID \
  {0x8868e871,0xe4f1,0x11d3,\
    {0xbc,0x22,0x00,0x80,0xc7,0x3c,0x88,0x81}}

#define ACPI_TABLE_GUID \
  {0xeb9d2d30,0x2d88,0x11d3,\

#define SMBIOS3_TABLE_GUID \
  {0xf2fd1544, 0x9794, 0x4a2c,\
   {0x99,0x2e,0xe5,0xbb,0xcf,0x20,0xe3,0x94})

#define MPS_TABLE_GUID \
  {0xeb9d2d2f,0x2d88,0x11d3,\
   {0x9a,0x16,0x00,0x90,0x27,0x3f,0xc1,0x4d}}
//
// ACPI 2.0 or newer tables should use EFI_ACPI_TABLE_GUID
//
#define EFI_ACPI_TABLE_GUID \
{0x8868e871,0xe4f1,0x11d3,\
{0xbc,0x22,0x00,0x80,0xc7,0x3c,0x88,0x81}}

#define EFI_ACPI_20_TABLE_GUID EFI_ACPI_TABLE_GUID

#define ACPI_TABLE_GUID \
{0xeb9d2d30,0x2d88,0x11d3,\
{0x9a,0x16,0x00,0x90,0x27,0x3f,0xc1,0x4d}}

#define ACPI_10_TABLE_GUID ACPI_TABLE_GUID*
```

4.6.1.2 JSON Configuration Tables

The following list shows the GUIDs for tables defined for reporting firmware configuration data to EFI Configuration Tables and also for processing JSON payload capsule as defined in Section 23.5. The address reported in the table entry identified by EFI_JSON_CAPSULE_DATA_TABLE_GUID will be referenced as physical and will not be fixed up when transition from preboot to runtime phase. The addresses reported in these table entries identified by EFI_JSON_CONFIG_DATA_TABLE_GUID and EFI_JSON_CAPSULE_RESULT_TABLE_GUID will be referenced as virtual and will be fixed up when transition from preboot to runtime phase.

```
#define EFI_JSON_CONFIG_DATA_TABLE_GUID \
{0x87367f87, 0x1119, 0x41ce, \
{0xaa, 0xec, 0x8b, 0xe0, 0x11, 0x1f, 0x55, 0x8a }}

#define EFI_JSON_CAPSULE_DATA_TABLE_GUID \
{0x35e7a725, 0x8dd2, 0x4cac, \
{ 0x80, 0x11, 0x33, 0xcd, 0xa8, 0x10, 0x90, 0x56 }}

#define EFI_JSON_CAPSULE_RESULT_TABLE_GUID \
{0xdbc461c3, 0xb3de, 0x422a,\
{0xb9, 0xb4, 0x98, 0x86, 0xfd, 0x49, 0xa1, 0xe5 }}
```

4.6.1.3 Devicetree Tables

The following list shows the GUIDs for the Devicetree table (DTB). For more information, see "Links to UEFI-Related Documents" (http://uefi.org/uefi) under the headings "Devicetree Specification". The DTB must be contained in memory of type EfiACPIReclaimMemory. The address reported in this table entry will be referenced as physical and will not be fixed up when transition from preboot to runtime phase. Firmware must have the DTB resident in memory and installed in the EFI system table before executing any UEFI applications or drivers that are not part of the system firmware image. Once the DTB is installed as a configuration table, the system firmware must not make any modification to it or reference any data contained within the DTB.

UEFI applications are permitted to modify or replace the loaded DTB. System firmware must not depend on any data contained within the DTB. If system firmware makes use of a DTB for its own configuration, it should use a separate private copy that is not installed in the EFI System Table or otherwise be exposed to EFI applications.

```
//
// Devicetree table, in Flattened Devicetree Blob (DTB) format
//
#define EFI_DTB_TABLE_GUID \
{0xb1b621d5, 0xf19c, 0x41a5, \
{0x83, 0x0b, 0xd9, 0x15, 0x2c, 0x69, 0xaa, 0xe0}}
```

4.6.2 EFI_RT_PROPERTIES_TABLE

This table should be published by a platform if it no longer supports all EFI runtime services once ExitBootServices() has been called by the OS. Note that this is merely a hint to the OS, which it is free to ignore, and so the platform is still required to provide callable implementations of unsupported runtime services that simply return EFI_UNSUPPORTED.

```
#define EFI_RT_PROPERTIES_TABLE_GUID \\
  { 0xeb66918a, 0x7eef, 0x402a, \\
    { 0x84, 0x2e, 0x93, 0x1d, 0x21, 0xc3, 0x8a, 0xe9 }}

```

(continues on next page)

(continued from previous page)

```
      typedef struct {
        UINT16 Version;
        UINT16 Length;
        UINT32 RuntimeServicesSupported;
    } EFI_RT_PROPERTIES_TABLE;
```

Version

Version of the table, must be 0x1

```
#define EFI_RT_PROPERTIES_TABLE_VERSION 0x1
```

Length

Size in bytes of the entire EFI_RT_PROPERTIES_TABLE, must be 8.

RuntimeServicesSupported

Bitmask of which calls are or are not supported, where a bit set to 1 indicates that the call is supported, and 0 indicates that it is not.

```
#define EFI_RT_SUPPORTED_GET_TIME                          0x0001
#define EFI_RT_SUPPORTED_SET_TIME                          0x0002
#define EFI_RT_SUPPORTED_GET_WAKEUP_TIME                   0x0004
#define EFI_RT_SUPPORTED_SET_WAKEUP_TIME                   0x0008
#define EFI_RT_SUPPORTED_GET_VARIABLE                      0x0010
#define EFI_RT_SUPPORTED_GET_NEXT_VARIABLE_NAME            0x0020
#define EFI_RT_SUPPORTED_SET_VARIABLE                      0x0040
#define EFI_RT_SUPPORTED_SET_VIRTUAL_ADDRESS_MAP           0x0080
#define EFI_RT_SUPPORTED_CONVERT_POINTER                   0x0100
#define EFI_RT_SUPPORTED_GET_NEXT_HIGH_MONOTONIC_COUNT     0x0200
#define EFI_RT_SUPPORTED_RESET_SYSTEM                      0x0400
#define EFI_RT_SUPPORTED_UPDATE_CAPSULE                    0x0800
#define EFI_RT_SUPPORTED_QUERY_CAPSULE_CAPABILITIES        0x1000
#define EFI_RT_SUPPORTED_QUERY_VARIABLE_INFO               0x2000
```

The address reported in the EFI configuration table entry of this type will be referenced as physical and will not be fixed up when transitioning from preboot to runtime phase.

4.6.3 EFI_PROPERTIES_TABLE (deprecated)

Note: This table is deprecated and should no longer be used! It will be removed from future versions of the specification. EFI_MEMORY_ATTRIBUTES_TABLE described below provides alternative mechanism to implement runtime memory protection.

This table is published if the platform meets some of the construction requirements listed in the *MemoryProtectionAttributes* .

```
typedef struct {
  UINT32          Version;
  UINT32          Length;
  UINT64          MemoryProtectionAttribute;
}   EFI_PROPERTIES_TABLE;
```

Version

This is revision of the table. Successive version may populate additional bits and growth the table length. In the case of the latter, the *Length* field will be adjusted appropriately

```
#define EFI_PROPERTIES_TABLE_VERSION 0x00010000
```

Length

This is the size of the entire EFI_PROPERTIES_TABLE structure, including the version. The initial version will be of length 16.

MemoryProtectionAttribute

This field is a bit mask. Any bits not defined shall be considered reserved. A set bit means that the underlying firmware has been constructed responsive to the given property.

```
//
// Memory attribute (Not defined bits are reserved)
//
#define EFI_PROPERTIES_RUNTIME_MEMORY_PROTECTION_NON_EXECUTABLE_PE_DATA     0x1
\
  // BIT 0 - description - implies the runtime data is separated     from the code
```

This bit implies that the UEFI runtime code and data sections of the executable image are separate and must be aligned as specified in *Calling Conventions* . This bit also implies that the data pages do not have any executable code.

It is recommended not to use this attribute, especially for implementations that broke the runtime code memory map descriptors into the underlying code and data sections within UEFI modules. This splitting causes interoperability issues with operating systems that invoke *SetVirtualAddress()* without realizing that there is a relationship between these runtime descriptors.

4.6.4 EFI_MEMORY_ATTRIBUTES_TABLE

Summary

When published by the system firmware, the EFI_MEMORY_ATTRIBUTES_TABLE provides additional information about regions within the run-time memory blocks defined in the EFI_MEMORY_DESCRIPTOR entries returned from EFI_BOOT_SERVICES . GetMemoryMap() function. The Memory Attributes Table is currently used to describe memory protections that may be applied to the EFI Runtime code and data by an operating system or hypervisor. Consumers of this table must currently ignore entries containing any values for *Type* except for *EfiRuntimeServicesData* and *EfiRuntimeServicesCode* to ensure compatibility with future uses of this table. The Memory Attributes Table may define multiple entries to describe sub-regions that comprise a single entry returned by GetMemoryMap() however the sub-regions must total to completely describe the larger region and may not cross boundaries between entries reported by GetMemoryMap() . If a run-time region returned in GetMemoryMap() entry is not described within the Memory Attributes Table, this region is assumed to not be compatible with any memory protections.

Only entire EFI_MEMORY_DESCRIPTOR entries as returned by GetMemoryMap() may be passed to SetVirtualAddressMap() .

The address reported in the EFI configuration table entry of this type will be referenced as physical and will not be fixed up when transition from preboot to runtime phase.

Prototype

```
#define EFI_MEMORY_ATTRIBUTES_TABLE_GUID \
  {0xdcfa911d, 0x26eb, 0x469f, \
    {0xa2, 0x20, 0x38, 0xb7, 0xdc, 0x46, 0x12, 0x20}}
```

With the following data structure

```
/***********************************************
/* EFI_MEMORY_ATTRIBUTES_TABLE
/***********************************************
typedef struct {
  UINT32                       Version ;
  UINT32                       NumberOfEntries ;
  UINT32                       DescriptorSize ;
  UINT32                       Reserved ;
  // EFI_MEMORY_DESCRIPTOR     Entry [1] ;
  }  EFI_MEMORY_ATTRIBUTES_TABLE;
```

Version
The version of this table. Present version is 0x00000001

NumberOfEntries
Count of EFI_MEMORY_DESCRIPTOR entries provided. This is typically the total number of PE/COFF sections within all UEFI modules that comprise the UEFI Runtime and all UEFI Data regions (e.g. runtime heap).

Entry
Array of *Entries* of type EFI_MEMORY_DESCRIPTOR.

DescriptorSize
Size of the memory descriptor.

Reserved
Reserved bytes.

Description

For each array entry, the EFI_MEMORY_DESCRIPTOR . *Attribute* field can inform a runtime agency, such as operating system or hypervisor, as to what class of protection settings can be made in the memory management unit for the memory defined by this entry. The only valid bits for *Attribute* field currently are EFI_MEMORY_RO , EFI_MEMORY_XP , plus EFI_MEMORY_RUNTIME . Irrespective of the memory protections implied by *Attribute* , the EFI_MEMORY_DESCRIPTOR . *Type* field should match the type of the memory in enclosing *SetMemoryMap()* entry. *PhysicalStart* must be aligned as specified in *Calling Conventions* . The list must be sorted by physical start address in ascending order. *VirtualStart* field must be zero and ignored by the OS since it has no purpose for this table. *NumPages* must cover the entire memory region for the protection mapping. Each Descriptor in the EFI_MEMORY_ATTRIBUTES_TABLE with attribute *EFI_MEMORY_RUNTIME* must not overlap any other Descriptor in the EFI_MEMORY_ATTRIBUTES_TABLE with attribute EFI_MEMORY_RUNTIME . Additionally, every memory region described by a Descriptor in *EFI_MEMORY_ATTRIBUTES_TABLE* must be a sub-region of, or equal to, a descriptor in the table produced by GetMemoryMap().

Table 4.1: Usage of Memory Attribute Definitions

	EFI_MEMORY_RO	**EFI_MEMORY_XP**	**EFI _MEMORY_RUNTIME**
No memory access protection is possible for Entry	0	0	1
Write-protected Code	1	0	1
Read/Write Data	0	1	1
Read-only Data	1	1	1

Other Configuration Tables

The following list shows additional configuration tables defined in this specification:

- EFI_MEMORY_RANGE_CAPSULE_GUID

- EFI_DEBUG_IMAGE_INFO_TABLE (Section 18.4.3)
- EFI_SYSTEM_RESOURCE_TABLE (Section 23.4)
- EFI_IMAGE_EXECUTION_INFO_TABLE (Section 32.5.3.1)
- User Information Table (Section 36.5)
- HII Database export buffer (Section 33.2.11.1, OS Runtime Utilization)

4.7 Image Entry Point Examples

The examples in the following sections show how the various table examples are presented in the UEFI environment.

4.7.1 Image Entry Point Examples

The following example shows the image entry point for a UEFI Application. This application makes use of the EFI System Table, the EFI Boot Services Table, and the EFI Runtime Services Table.

```
EFI_SYSTEM_TABLE                *gST;
EFI_BOOT_SERVICES               *gBS;
EFI_RUNTIME_SERVICES            *gRT;

EfiApplicationEntryPoint(
  IN EFI_HANDLE                 ImageHandle,
  IN EFI_SYSTEM_TABLE           *SystemTable
  )

 {
  EFI_STATUS Status;
  EFI_TIME                       *Time;

  gST = SystemTable;
  gBS = gST->BootServices;
  gRT = gST->RuntimeServices;

  //
  // Use EFI System Table to print "Hello World" to the active console output
  // device.
  //
  Status = gST->ConOut->OutputString (gST->ConOut, L"Hello world\n\r"); if (EFI_ERROR␣
↪(Status)) {
   return Status;
  }

  //
  // Use EFI Boot Services Table to allocate a buffer to store the current time
  // and date.
  //
  Status = gBS->AllocatePool (
       EfiBootServicesData,
       sizeof (EFI_TIME),
       (VOID \**)&Time
```

(continues on next page)

(continued from previous page)

```
        );
   if (EFI_ERROR (Status)) {
    return Status;
   }

   //
   // Use the EFI Runtime Services Table to get the current time and date.
   //
   Status = gRT->GetTime (Time, NULL)
   if (EFI_ERROR (Status)) {
    return Status;
   }

   return Status;
}
```

The following example shows the UEFI image entry point for a driver that does not follow the UEFI *Driver Model* . Since this driver returns EFI_SUCCESS , it will stay resident in memory after it exits.

```
EFI_SYSTEM_TABLE         *gST;
EFI_BOOT_SERVICES        *gBS;
EFI_RUNTIME_SERVICES     *gRT;

EfiDriverEntryPoint(
  IN EFI_HANDLE            ImageHandle,
  IN EFI_SYSTEM_TABLE      *SystemTable
  )

{
  gST = SystemTable;
  gBS = gST->BootServices;
  gRT = gST->RuntimeServices;

  //
  // Implement driver initialization here.
  //

   return EFI_SUCCESS;
}
```

The following example shows the UEFI image entry point for a driver that also does not follow the UEFI *Driver Model* . Since this driver returns EFI_DEVICE_ERROR, it will not stay resident in memory after it exits.

```
EFI_SYSTEM_TABLE          *gST;
EFI_BOOT_SERVICES         *gBS;
EFI_RUNTIME_SERVICES      *gRT;

EfiDriverEntryPoint(
  IN EFI_HANDLE            ImageHandle,
  IN EFI_SYSTEM_TABLE      *SystemTable
  )
```

(continues on next page)

(continued from previous page)

```
{
  gST = SystemTable;
  gBS = gST->BootServices;
  gRT = gST->RuntimeServices;

  //
  // Implement driver initialization here.
  //

  return EFI_DEVICE_ERROR;
}
```

4.7.2 UEFI Driver Model Example

The following is an UEFI Driver Model example that shows the driver initialization routine for the ABC device controller that is on the XYZ bus. The EFI_DRIVER_BINDING_PROTOCOL and the function prototypes for AbcSupported(), AbcStart(), and AbcStop() are defined in *EFI Driver Binding Protocol* This function saves the driver's image handle and a pointer to the EFI boot services table in global variables, so the other functions in the same driver can have access to these values. It then creates an instance of the EFI_DRIVER_BINDING_PROTOCOL and installs it onto the driver's image handle.

```
extern EFI_GUID              gEfiLoadedImageProtocolGuid;
extern EFI_GUID              gEfiDriverBindingProtocolGuid;
EFI_BOOT_SERVICES            *gBS;
static EFI_DRIVER_BINDING_PROTOCOL  mAbcDriverBinding = {
  AbcSupported,
  AbcStart,
  AbcStop,
  1,
  NULL,
  NULL
};

AbcEntryPoint(
  IN EFI_HANDLE                ImageHandle,
  IN EFI_SYSTEM_TABLE          *SystemTable
  )

{
  EFI_STATUS Status;

  gBS = SystemTable->BootServices;

  mAbcDriverBinding->ImageHandle      = ImageHandle;
  mAbcDriverBinding->DriverBindingHandle = ImageHandle;

  Status = gBS->InstallMultipleProtocolInterfaces(
           &mAbcDriverBinding->DriverBindingHandle,
           &gEfiDriverBindingProtocolGuid, &mAbcDriverBinding,
            NULL
            );
```

(continues on next page)

(continued from previous page)

```
  return Status;
}
```

4.7.3 UEFI Driver Model Example (Unloadable)

The following is the same UEFI Driver Model example as above, except it also includes the code required to allow the driver to be unloaded through the boot service Unload() *EFI_LOADED_IMAGE_PROTOCOL.Unload()* . Any protocols installed or memory allocated in AbcEntryPoint() must be uninstalled or freed in the AbcUnload().

```
extern EFI_GUID                       gEfiLoadedImageProtocolGuid;
extern EFI_GUID                       gEfiDriverBindingProtocolGuid;
EFI_BOOT_SERVICES                     *gBS;
static EFI_DRIVER_BINDING_PROTOCOL    mAbcDriverBinding = {
  AbcSupported,
  AbcStart,
  AbcStop,
  1,
  NULL,
  NULL
};

EFI_STATUS
AbcUnload (
  IN EFI_HANDLE                       ImageHandle
  );
AbcEntryPoint(
  IN EFI_HANDLE                       ImageHandle,
  IN EFI_SYSTEM_TABLE                 *SystemTable
  )

{
  EFI_STATUS                          Status;
  EFI_LOADED_IMAGE_PROTOCOL           *LoadedImage;

  gBS = SystemTable->BootServices;

  Status = gBS->OpenProtocol (
           ImageHandle,
           &gEfiLoadedImageProtocolGuid,
           &LoadedImage,
           ImageHandle,
           NULL,
           EFI_OPEN_PROTOCOL_GET_PROTOCOL
           );
  if (EFI_ERROR (Status)) {
    return Status;
}
LoadedImage->Unload = AbcUnload;

mAbcDriverBinding->ImageHandle         = ImageHandle;
mAbcDriverBinding->DriverBindingHandle = ImageHandle;
```

(continues on next page)

(continued from previous page)

```
 Status =  gBS->InstallMultipleProtocolInterfaces(
           &mAbcDriverBinding->DriverBindingHandle,
           &gEfiDriverBindingProtocolGuid, &mAbcDriverBinding,
           NULL
           );

   return Status;
 }

 EFI_STATUS Status
 AbcUnload (
   IN EFI_HANDLE ImageHandle
   )

{
 EFI_STATUS Status;

 Status =  gBS->UninstallMultipleProtocolInterfaces (
           ImageHandle,
           &gEfiDriverBindingProtocolGuid, &mAbcDriverBinding,
           NULL
           );
      return Status;
    }
```

4.7.4 EFI Driver Model Example (Multiple Instances)

The following is the same as the first UEFI *Driver Model* example, except it produces three *EFI Driver Binding Protocol* instances. The first one is installed onto the driver's image handle. The other two are installed onto newly created handles.

```
extern EFI_GUID             gEfiDriverBindingProtocolGuid;
EFI_BOOT_SERVICES           *gBS;

static EFI_DRIVER_BINDING_PROTOCOL   mAbcDriverBindingA = {
  AbcSupportedA,
  AbcStartA,
  AbcStopA,
  1,
  NULL,
  NULL
};

static EFI_DRIVER_BINDING_PROTOCOL   mAbcDriverBindingB = {
  AbcSupportedB,
  AbcStartB,
  AbcStopB,
  1,
  NULL,
  NULL
```

(continues on next page)

(continued from previous page)

```
};

static EFI_DRIVER_BINDING_PROTOCOL   mAbcDriverBindingC = {
  AbcSupportedC,
  AbcStartC,
  AbcStopC,
  1,
  NULL,
  NULL
};

AbcEntryPoint(
  IN EFI_HANDLE ImageHandle,
  IN EFI_SYSTEM_TABLE *SystemTable
  )

{
  EFI_STATUS Status;

  gBS = SystemTable->BootServices;

  //
  // Install mAbcDriverBindingA onto ImageHandle
  //
  mAbcDriverBindingA->ImageHandle           = ImageHandle;
  mAbcDriverBindingA->DriverBindingHandle    = ImageHandle;

  Status =  gBS->InstallMultipleProtocolInterfaces(
            &mAbcDriverBindingA->DriverBindingHandle,
            &gEfiDriverBindingProtocolGuid, &mAbcDriverBindingA,
            NULL
            );
  if (EFI_ERROR (Status)) {
     return Status;
  }

  //
  // Install mAbcDriverBindingB onto a newly created handle
  //
  mAbcDriverBindingB->ImageHandle      = ImageHandle;
  mAbcDriverBindingB->DriverBindingHandle      = NULL;

  Status =  gBS->InstallMultipleProtocolInterfaces(
            &mAbcDriverBindingB->DriverBindingHandle,
            &gEfiDriverBindingProtocolGuid, &mAbcDriverBindingB,
            NULL
            );
  if (EFI_ERROR (Status)) {
     return Status;
  }

  //
```

(continues on next page)

(continued from previous page)

```
// Install mAbcDriverBindingC onto a newly created handle
//
mAbcDriverBindingC->ImageHandle = ImageHandle;
mAbcDriverBindingC->DriverBindingHandle = NULL;

Status =  gBS->InstallMultipleProtocolInterfaces(
          &mAbcDriverBindingC->DriverBindingHandle,
          &gEfiDriverBindingProtocolGuid, &mAbcDriverBindingC,
          NULL
          );

return Status;
}
```

CHAPTER

FIVE

GUID PARTITION TABLE (GPT) DISK LAYOUT

5.1 GPT and MBR disk layout comparison

This specification defines the GUID Partition table (GPT) disk layout (i.e., partitioning scheme). The following list outlines the advantages of using the GPT disk layout over the legacy Master Boot Record (MBR) disk layout:

- Logical Block Addresses (LBAs) are 64 bits (rather than 32 bits).
- Supports many partitions (rather than just four primary partitions).
- Provides both a primary and backup partition table for redundancy.
- Uses version number and size fields for future expansion.
- Uses CRC32 fields for improved data integrity.
- Defines a GUID for uniquely identifying each partition.
- Uses a GUID and attributes to define partition content type.
- Each partition contains a 36 character human readable name.

5.2 LBA 0 Format

LBA 0 (i.e., the first logical block) of the hard disk contains either

- a legacy Master Boot Record (MBR) (See *Legacy Master Boot Record (MBR)*)
- or a protective MBR (See *Protective MBR*).

5.2.1 Legacy Master Boot Record (MBR)

A legacy MBR may be located at LBA 0 (i.e., the first logical block) of the disk if it is not using the GPT disk layout (i.e., if it is using the MBR disk layout). The boot code on the MBR is not executed by UEFI firmware.

Table 5.1: Legacy MBR

Mnemonic	**Byte Offset**	**Byte Length**	**Description**
BootCode	0	424	x86 code used on a non-UEFI system to select an MBR partition record and load the first logical block of that partition . This code shall not be executed on UEFI systems.

continues on next page

Table 5.1 – continued from previous page

UniqueMB RDiskSignature	440	4	Unique Disk Signature This may be used by the OS to identify the disk from other disks in the system. This value is always written by the OS and is never written by EFI firmware.
Unknown	444	2	Unknown. This field shall not be used by UEFI firmware.
PartitionRecord	446	16*4	Array of four legacy MBR partition records (See *Legacy MBR Partition Record*).
Signature	510	2	Set to 0xAA55 (i.e., byte 510 contains 0x55 and byte 5 11 contains 0xAA).
Reserved	512	Logical BlockSize - 512	The rest of the logical block, if any, is reserved.

The MBR contains four partition records (see Table 11) that each define the beginning and ending LBAs that a partition consumes on a disk.

Table 5.2: Legacy MBR Partition Record

Mnemonic	**Byte Offset**	**Byte Length**	**Description**
BootIndicator	0	1	0x80 indicates that this is the bootable legacy partition. Other values indicate that this is not a bootable legacy partition. This field shall not be used by UEFI firmware.
StartingCHS	1	3	Start of partition in CHS address format. This field shall not be used by UEFI firmware.
OSType	4	1	Type of partition. See See *OS Types* .
EndingCHS	5	3	End of partition in CHS address format. This field shall not be used by UEFI firmware.
StartingLBA	8	4	Starting LBA of the partition on the disk. This field is used by UEFI firmware to determine the start of the partition.
SizeInLBA	12	4	Size of the partition in LBA units of logical blocks. This field is used by UEFI firmware to determine the size of the partition.

If an MBR partition has an *OSType* field of 0xEF (i.e., UEFI System Partition), then the firmware must add the UEFI System Partition GUID to the handle for the MBR partition using *InstallProtocolInterface()* . This allows drivers and applications, including OS loaders, to easily search for handles that represent UEFI System Partitions.

The following test must be performed to determine if a legacy MBR is valid:

- The Signature must be 0xaa55
- A Partition Record that contains an *OSType* value of zero or a *SizeInLBA* value of zero may be ignored.

Otherwise:

- The partition defined by each MBR Partition Record must physically reside on the disk (i.e., not exceed the capacity of the disk).
- Each partition must not overlap with other partitions.

Figure 5.1 (below) shows an example of an MBR disk layout with four partitions.

   MBR_PARTITION_RECORD Partition[4];
   UINT16         Signature;
}   MASTER_BOOT_RECORD;

#pragma pack()
```

5.2.2 OS Types

Unique types defined by this specification (other values are not defined by this specification):

- 0xEF (i.e., UEFI System Partition) defines a UEFI system partition.
- 0xEE (i.e., GPT Protective) is used by a protective MBR (see 5.2.2) to define a fake partition covering the entire disk.

Other values are used by legacy operating systems, and are allocated independently of the UEFI specification.

NOTE: *"Partition types" by Andries Brouwer: See "Links to UEFI-Related Documents"* (http://uefi.org/uefi) *under the heading "OS Type values used in the MBR disk layout".*

5.2.3 Protective MBR

For a bootable disk, a Protective MBR must be located at LBA 0 (i.e., the first logical block) of the disk if it is using the GPT disk layout. The Protective MBR precedes the GUID Partition Table Header to maintain compatibility with existing tools that do not understand GPT partition structures.

Table 5.3: Protective MBR

Mnemonic	Byte Offset	Byte Length	Contents
Boot Code	0	440	Unused by UEFI systems.
Unique MBR Disk Signature	440	4	Unused. Set to zero.
Unknown	444	2	Unused. Set to zero.
Partition Record	446	16*4	Array of four MBR partition records. Contains: • one partition record as defined See Table (below); and • three partition records each set to zero.
Signature	510	2	Set to 0xAA55 (i.e., byte 510 contains 0x55 and byte 511 contains 0xAA).
Reserved	512	Logical Block Size - 512	The rest of the logical block, if any, is reserved. Set to zero.

One of the Partition Records shall be as defined in table 12, reserving the entire space on the disk after the Protective MBR itself for the GPT disk layout.

Table 5.4: Protective MBR Partition Record protecting the entire disk*

Mnemonic	Byte Offset	Byte Length	Description
BootIndicator	0	1	Set to 0x00 to indicate a non-bootable partition. If set to any value other than 0x00 the behavior of this flag on non-UEFI systems is undefined. Must be ignored by UEFI i mplementations.
StartingCHS	1	3	Set to 0x000200, corresponding to the Starting LBA field.
OSType	4	1	Set to 0xEE (i.e., GPT Protective)
EndingCHS	5	3	Set to the CHS address of the last logical block on the disk. Set to 0xFFFFFF if it is not possible to represent the value in this field.

continues on next page

Table 5.4 – continued from previous page

StartingLBA	8	4	Set to 0x00000001 (i.e., the LBA of the GPT Partition Header).
SizeInLBA	12	4	Set to the size of the disk minus one. Set to 0xFFFFFFFF if the size of the disk is too large to be represented in this field.

The remaining Partition Records shall each be set to zeros.

Figure 5.2 (below) shows an example of a GPT disk layout with four partitions with a protective MBR.

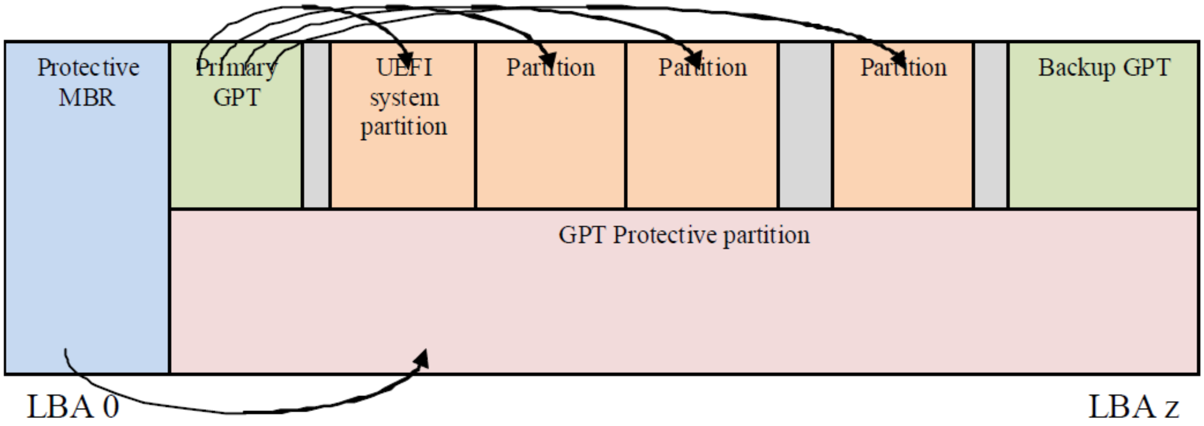

Fig. 5.2: GPT disk layout with protective MBR

Figure 5.3 (below) shows an example of a GPT disk layout with four partitions with a protective MBR, where the disk capacity exceeds LBA 0xFFFFFFFF.

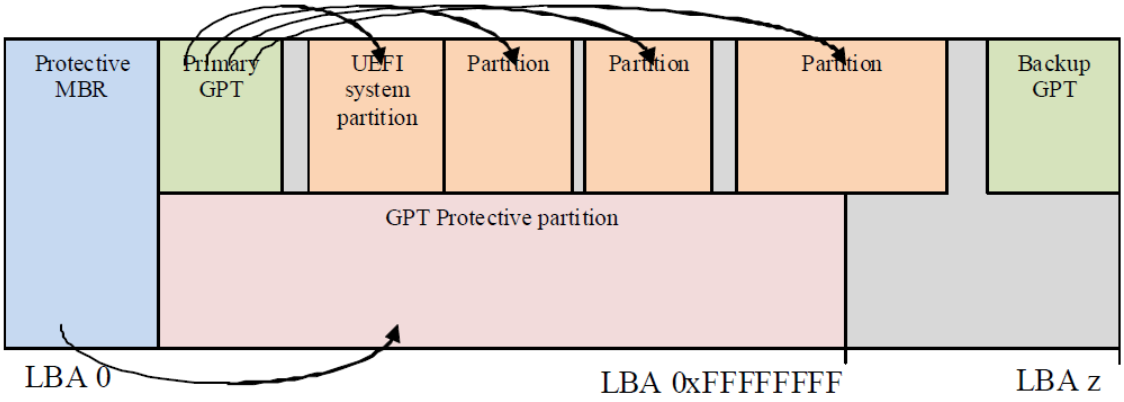

Fig. 5.3: GPT disk layout with protective MBR on a diskwith capacity > LBA 0xFFFFFFFF

5.2.4 Partition Information

Install an EFI_PARTITION_INFO protocol on each of the device handles that logical EFI_BLOCK_IO_PROTOTOLs are installed.

5.3 GUID Partition Table (GPT) Disk Layout

5.3.1 GPT overview

The GPT partitioning scheme is depicted in the Figure *GUID Partition Table (GPT) example* . The GPT Header (*GPT Header*) includes a signature and a revision number that specifies the format of the data bytes in the partition header. The GUID Partition Table Header contains a header size field that is used in calculating the CRC32 that confirms the integrity of the GPT Header. While the GPT Header's size may increase in the future it cannot span more than one logical block on the device.

LBA 0 (i.e., the first logical block) contains a protective MBR (See *Protective MBR*).

Two GPT Header structures are stored on the device: the primary and the backup. The primary GPT Header must be located in LBA 1 (i.e., the second logical block), and the backup GPT Header must be located in the last LBA of the device. Within the GPT Header the *My LBA* field contains the LBA of the GPT Header itself, and the *Alternate LBA* field contains the LBA of the other GPT Header. For example, the primary GPT Header's *My LBA* value would be 1 and its *Alternate LBA* would be the value for the last LBA of the device. The backup GPT Header's fields would be reversed.

The GPT Header defines the range of LBAs that are usable by GPT Partition Entries. This range is defined to be inclusive of *First Usable LBA* through *Last Usable LBA* on the logical device. All data stored on the volume must be stored between the *First Usable LBA* through *Last Usable LBA* , and only the data structures defined by UEFI to manage partitions may reside outside of the usable space. The value of *Disk GUID* is a GUID that uniquely identifies the entire GPT Header and all its associated storage. This value can be used to uniquely identify the disk. The start of the GPT Partition Entry Array is located at the LBA indicated by the *Partition Entry LBA* field. The size of a GUID Partition Entry element is defined in the *Size Of Partition Entry* field. There is a 32-bit CRC of the GPT Partition Entry Array that is stored in the GPT Header in *Partition Entry Array CRC32* field. The size of the GPT Partition Entry Array is S *ize Of Partition Entry* multiplied by *Number Of Partition Entries* . If the size of the GUID Partition Entry Array is not an even multiple of the logical block size, then any space left over in the last logical block is Reserved and not covered by the *Partition Entry Array CRC32* field. When a GUID Partition Entry is updated, the *Partition Entry Array CRC32* must be updated. When the *Partition Entry Array CRC32* is updated, the GPT Header CRC must also be updated, since the *Partition Entry Array CRC32* is stored in the GPT Header.

The primary GPT Partition Entry Array must be located after the primary GPT Header and end before the *First Usable LBA*. The backup GPT Partition Entry Array must be located after the *Last Usable LBA* and end before the backup GPT Header.

Therefore the primary and backup GPT Partition EntryArrays are stored in separate locations on the disk. Each GPT Partition Entry defines a partition that is contained in a range that is within the usable space declared by the GPT Header. Zero or more GPT Partition Entries may be in use in the GPT Partition Entry Array. Each defined partition must not overlap with any other defined partition. If all the fields of a GUID Partition Entry are zero, the entry is not in use. A minimum of 16,384 bytes of space must be reserved for the GPT Partition Entry Array.

If the block size is 512, the *First Usable LBA* must be greater than or equal to 34 (allowing 1 block for the Protective MBR, 1 block for the Partition Table Header, and 32 blocks for the GPT Partition Entry Array); if the logical block size is 4096, the *First Useable LBA* must be greater than or equal to 6 (allowing 1 block for the Protective MBR, 1 block for the GPT Header, and 4 blocks for the GPT Partition Entry Array).

The device may present a logical block size that is not 512 bytes long. In ATA, this is called the Long Logical Sector feature set; an ATA device reports support for this feature set in IDENTIFY DEVICE data word 106 bit 12 and reports

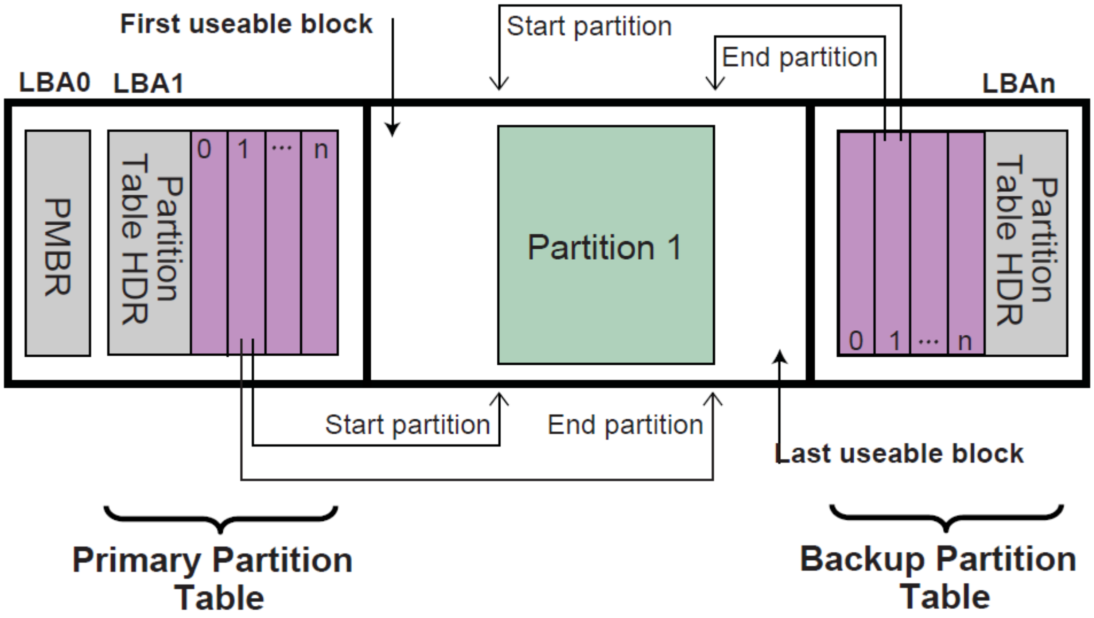

Fig. 5.4: GUID Partition Table (GPT) example

the number of words (i.e., 2 bytes) per logical sector in IDENTIFY DEVICE data words 117-118 (see ATA8-ACS). A SCSI device reports its logical block size in the READ CAPACITY parameter data Block Length In Bytes field (see SBC-3).

The device may present a logical block size that is smaller than the physical block size (e.g., present a logical block size of 512 bytes but implement a physical block size of 4,096 bytes). In ATA, this is called the Long Physical Sector feature set; an ATA device reports support for this feature set in IDENTIFY DEVICE data word 106 bit 13 and reports the Physical Sector Size/Logical Sector Size exponential ratio in IDENTIFY DEVICE data word 106 bits 3-0 (See ATA8-ACS). A SCSI device reports its logical block size/physical block exponential ratio in the READ CAPACITY (16) parameter data Logical Blocks Per Physical Block Exponent field (see SBC-3).These fields return 2 *x* logical sectors per physical sector (e.g., 3 means 2 *3* =8 logical sectors per physical sector).

A device implementing long physical blocks may present logical blocks that are not aligned to the underlying physical block boundaries. An ATA device reports the alignment of logical blocks within a physical block in IDENTIFY DEVICE data word 209 (see ATA8-ACS). A SCSI device reports its alignment in the READ CAPACITY (16) parameter data Lowest Aligned Logical Block Address field (see SBC-3). Note that the ATA and SCSI fields are defined differently (e.g., to make LBA 63 aligned, ATA returns a value of 1 while SCSI returns a value of 7).

In SCSI devices, the Block Limits VPD page Optimal Transfer Length Granularity field (see SBC-3) may also report a granularity that is important for alignment purposes (e.g., RAID controllers may return their RAID stripe depth in that field)

GPT partitions should be aligned to the larger of:

a – The physical block boundary, if any

b – The optimal transfer length granularity, if any.

For example

a – If the logical block size is 512 bytes, the physical block size is 4,096 bytes (i.e., 512 bytes x 8 logical blocks), there is no optimal transfer length granularity, and logical block 0 is aligned to a physical block boundary, then each GPT partition should start at an LBA that is a multiple of 8.

b – If the logical block size is 512 bytes, the physical block size is 8,192 bytes (i.e., 512 bytes x 16 logical blocks), the optimal transfer length granularity is 65,536 bytes (i.e., 512 bytes x 128 logical blocks), and logical block 0 is aligned to a physical block boundary, then each GPT partition should start at an LBA that is a multiple of 128.

To avoid the need to determine the physical block size and the optimal transfer length granularity, software may align GPT partitions at significantly larger boundaries. For example, assuming logical block 0 is aligned, it may use LBAs that are multiples of 2,048 to align to 1,048,576 byte (1 MiB) boundaries, which supports most common physical block sizes and RAID stripe sizes.

5.3.2 GPT Header

See Table (below) which defines the GPT Header.

Table 5.5: GPT Header

Mnemonic	Byte Offset	Byte Length	Description
Signature	0	8	Identifies EFI-compatible partition table header. This value must contain the ASCII string “EFI PART”, encoded as the 64-bit constant 0x54 52415020494645.
Revision	8	4	The revision number for this header. This revision value is not related to the UEFI Specification version. This header is version 1.0, so the correct value is 0x00010000.
HeaderSize	12	4	Size in bytes of the GPT Header. The *HeaderSize* must be greater than or equal to 92 and must be less than or equal to the logical block size.
HeaderCRC32	16	4	CRC32 checksum for the GPT Header structure. This value is computed by setting this field to 0, and computing the 32-bit CRC for *HeaderSize* bytes.
Reserved	20	4	Must be zero.
MyLBA	24	8	The LBA that contains this data structure.
AlternateLBA	32	8	LBA address of the alternate GPT Header.
FirstUsableLBA	40	8	The first usable logical block that may be used by a partition described by a GUID Partition Entry.
LastUsableLBA	48	8	The last usable logical block that may be used by a partition described by a GUID Partition Entry.
DiskGUID	56	16	GUID that can be used to uniquely identify the disk.
Par titionEntryLBA	72	8	The starting LBA of the GUID Partition Entry array.
NumberOfPa rtitionEntries	80	4	The number of Partition Entries in the GUID Partition Entry array.

continues on next page

Table 5.5 – continued from previous page

SizeOfPartitionEntry	84	4	The size, in bytes, of each the GUID Partition Entry structures in the GUID Partition Entry array. This field shall be set to a value of 128 x 2 *n* where n is an integer greater than or equal to zero (e.g., 128, 256, 512, etc.). NOTE: Previous versions of this specification allowed any multiple of 8..
PartitionEntryArrayCRC32	88	4	The CRC32 of the GUID Partition Entry array. Starts at *PartitionEntryLBA* and is computed over a byte length of *NumberOfPartitionEntries* * *SizeOfPartitionEntry.*
Reserved	92	BlockSize - 92	The rest of the block is reserved by UEFI and must be zero.

The following test must be performed to determine if a GPT is valid:

- Check the Signature
- Check the Header CRC
- Check that the *MyLBA* entry points to the LBA that contains the GUID Partition Table
- Check the CRC of the GUID Partition Entry Array

If the GPT is the primary table, stored at LBA 1:

- Check the *AlternateLBA* to see if it is a valid GPT

If the primary GPT is corrupt, software must check the last LBA of the device to see if it has a valid GPT Header and point to a valid GPT Partition Entry Array. If it points to a valid GPT Partition Entry Array, then software should restore the primary GPT if allowed by platform policy settings (e.g. a platform may require a user to provide confirmation before restoring the table, or may allow the table to be restored automatically). Software must report whenever it restores a GPT.

Software should ask a user for confirmation before restoring the primary GPT and must report whenever it does modify the media to restore a GPT. If a GPT formatted disk is reformatted to the legacy MBR format by legacy software, the last logical block might not be overwritten and might still contain a stale GPT. If GPT-cognizant software then accesses the disk and honors the stale GPT, it will misinterpret the contents of the disk. Software may detect this scenario if the legacy MBR contains valid partitions rather than a protective MBR (*Legacy Master Boot Record (MBR)*).

Any software that updates the primary GPT must also update the backup GPT. Software may update the GPT Header and GPT Partition Entry Array in any order, since all the CRCs are stored in the GPT Header. Software must update the backup GPT before the primary GPT, so if the size of device has changed (e.g. volume expansion) and the update is interrupted, the backup GPT is in the proper location on the disk

If the primary GPT is invalid, the backup GPT is used instead and it is located on the last logical block on the disk. If the backup GPT is valid it must be used to restore the primary GPT. If the primary GPT is valid and the backup GPT is invalid software must restore the backup GPT. If both the primary and backup GPTs are corrupted this block device is defined as not having a valid GUID Partition Header.

Both the primary and backup GPTs must be valid before an attempt is made to grow the size of a physical volume. This is due to the GPT recovery scheme depending on locating the backup GPT at the end of the device. A volume may grow in size when disks are added to a RAID device. As soon as the volume size is increased the backup GPT must be moved to the end of the volume and the primary and backup GPT Headers must be updated to reflect the new volume size.

5.3.3 GPT Partition Entry Array

The GPT Partition Entry Array contains an array of GPT Partition Entries. See Table (below) which defines the GPT Partition Entry.

Table 5.6: GPT Partition Entry

Mnemonic	Byte Offset	Byte Length	Description
PartitionTypeGUID	0	16	Unique ID that defines the purpose and type of this Partition. A value of zero defines that this partition entry is not being used.
UniquePartitionGUID	16	16	GUID that is unique for every partition entry. Every partition ever created will have a unique GUID. This GUID must be assigned when the GPT Partition Entry is created. The GPT Partition Entry is created whenever the *NumberOfPa rtitionEntries* in the GPT Header is increased to include a larger range of addresses.
StartingLBA	32	8	Starting LBA of the partition defined by this entry.
EndingLBA	40	8	Ending LBA of the partition defined by this entry.
Attributes	48	8	Attribute bits, all bits reserved by UEFI (*Defined GPT Partition Entry — Partition Type GUIDs*.
PartitionName	56	72	Null-terminated string containing a human-readable name of the partition.
Reserved	128	*SizeOf PartitionEntry* - 128	The rest of the GPT Partition Entry, if any, is reserved by UEFI and must be zero.

The *SizeOfPartitionEntry* variable in the GPT Header defines the size of each GUID Partition Entry. Each partition entry contains a *Unique Partition GUID* value that uniquely identifies every partition that will ever be created. Any time a new partition entry is created a new GUID must be generated for that partition, and every partition is guaranteed to have a unique GUID. The partition is defined as all the logical blocks inclusive of the *StartingLBA* and *EndingLBA* .

The *PartitionTypeGUID* field identifies the contents of the partition. This GUID is similar to the *OS Type* field in the MBR. Each filesystem must publish its unique GUID. The *Attributes* field can be used by utilities to make broad inferences about the usage of a partition and is defined in Table (below).

The firmware must add the *PartitionTypeGuid* to the handle of every active GPT partition using *EFI_BOOT_SERVICES.InstallProtocolInterface()* . This will allow drivers and applications, including OS loaders, to easily search for handles that represent EFI System Partitions or vendor specific partition types.

Software that makes copies of GPT-formatted disks and partitions must generate new *Disk GUID* values in the GPT Headers and new *Unique Partition GUID* values in each GPT Partition Entry. If GPT-cognizant software encounters two disks or partitions with identical GUIDs, results will be indeterminate.

Table 5.7: Defined GPT Partition Entry — Partition Type GUIDs

Description	GUID Value
Unused Entry	00000000-0000-0000-0000-000000000000
EFI System Partition	C12A7328-F81F-11D2-BA4B-00A0C93EC93B
Partition containing a legacy MBR	024DEE41-33E7-11D3-9D69-0008C781F39F

OS vendors need to generate their own Partition Type GUIDs to identify their partition types.

Table 5.8: Defined GPT Partition Entry - Attributes

Bits	Name	Description
Bit 0	Required Partition	If this bit is set, the partition is required for the platform to function. The owner/creator of the partition indicates that deletion or modification of the contents can result in loss of platform features or failure for the platform to boot or operate. The system cannot function normally if this partition is removed, and it should be considered part of the hardware of the system. Actions such as running diagnostics, system recovery, or even OS install or boot could potentially stop working if this partition is removed. Unless OS software or firmware recognizes this partition, it should never be removed or modified as the UEFI firmware or platform hardware may become non-functional.
Bit 1	No Block IO Protocol	If this bit is set, then firmware must not produce an *EFI_BLOCK_IO_PROTOCOL* device for this partition. See *Partition Discovery* for more details. By not producing an *EFI_BLOCK_IO_PROTOCOL* partition, file system mappings will not be created for this partition in UEFI.
Bit 2	Legacy BIOS Bootable	This bit is set aside by this specification to let systems with traditional PC-AT BIOS firmware implementations inform certain limited, special-purpose software running on these systems that a GPT partition may be bootable. For systems with firmware implementations conforming to this specification, the UEFI boot manager (see chapter 3) must ignore this bit when selecting a UEFI-compliant application, e.g., an OS loader (see 2.1.3). Therefore there is no need for this specification to define the exact meaning of this bit.
Bits 3-47		Undefined and must be zero. Reserved for expansion by future versions of the UEFI specification.
Bits 48-63		Reserved for GUID specific use. The use of these bits will vary depending on the *PartitionTypeGUID* . Only the owner of the *PartitionTypeGUID* is allowed to modify these bits. They must be preserved if Bits 0-47 are modified.

BLOCK TRANSLATION TABLE (BTT) LAYOUT

This specification defines the Block Translation Table (BTT) metadata layout. The following sub-sections outline the BTT format that is utilized on the media, the data structures involved, and a detailed description of how SW is to interpret the BTT layout.

6.1 Block Translation Table (BTT) Background

A namespace defines a contiguously-addressed range of Non-Volatile Memory conceptually similar to a SCSI Logical Unit (LUN) or a NVM Express namespace.

Any namespace being utilized for block storage may contain a Block Translation Table (BTT), which is a layout and set of rules for doing block I/O that provide powerfail write atomicity of a single block. Traditional block storage, including hard disks and SSDs, usually protect against torn sectors, which are sectors partially written when interrupted by power failure. Existing software, mostly file systems, depend on this behavior, often without the authors realizing it. To enable such software to work correctly on namespaces supporting block storage access, the BTT layout defined by this document sub-divides a namespace into one or more BTT Arenas, which are large sections of the namespace that contain the metadata required to provide the desired write atomicity. Each of these BTT Arenas contains a metadata layout as shown in Figures 6-1 and 6-2 below.

Each arena contains the layout shown in Figure 6-1 (above), the primary info block, data area, map, flog, and a backup info block. Each of these areas is described in the following sections. When the namespace is larger than 512 GiB, multiple arenas are required by the BTT layout, as shown in Figure 6-2 (below). Each namespace using a BTT is divided into as many 512 GiB arenas as shall fit, followed by a smaller arena to contain any remaining space as appropriate. The smallest arena size is 16MiB so the last arena size shall be between 16MiB and 512GiBs. Any remaining space less than 16MiB is unused. Because of these rules for arena placement, software can locate every primary Info block and every backup Info block without reading any metadata, based solely on the namespace size.

6.2 Block Translation Table (BTT) Data Structures

The following sub-sections outline the data structures associated with the BTT Layout.

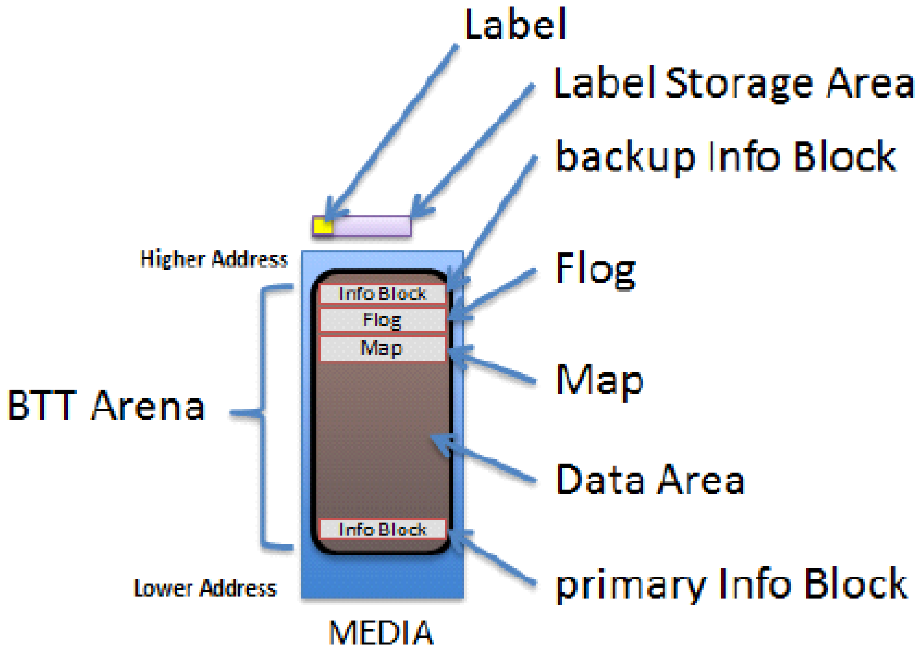

Fig. 6.1: The BTT Layout in a BTT Arena

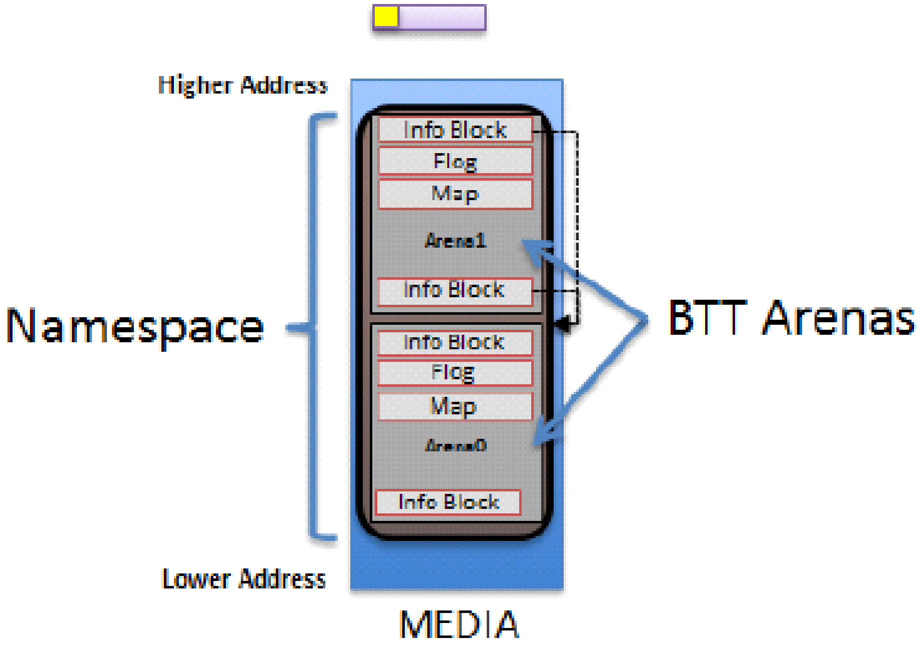

Fig. 6.2: A BTT With Multiple Arenas in a Large Namespace

6.2.1 BTT Info Block

```
// Alignment of all BTT structures
#define EFI_BTT_ALIGNMENT 4096
#define EFI_BTT_INFO_UNUSED_LEN 3968

#define EFI_BTT_INFO_BLOCK_SIG_LEN 16

// Constants for Flags field
#define EFI_BTT_INFO_BLOCK_FLAGS_ERROR 0x00000001

// Constants for Major and Minor version fields
#define EFI_BTT_INFO_BLOCK_MAJOR_VERSION 2
#define EFI_BTT_INFO_BLOCK_MINOR_VERSION 0

typdef struct _EFI_BTT_INFO_BLOCK {
CHAR8 Sig[EFI_BTT_INFO_BLOCK_SIG_LEN];
  EFI_GUID  Uuid;
  EFI_GUID  ParentUuid;
  UINT32    Flags;
  UINT16    Major;
  UINT16    Minor;
  UINT32    ExternalLbaSize;
  UINT32    ExternalNLba;
  UINT32    InternalLbaSize;
  UINT32    InternalNLba;
  UINT32    NFree;
  UINT32    InfoSize;
  UINT64    NextOff;
  UINT64    DataOff;
  UINT64    MapOff;
  UINT64    FlogOff;
  UINT64    InfoOff;
  CHAR8     Unused[EFI_BTT_INFO_UNUSED_LEN];
  UINT64    Checksum;
}  EFI_BTT_INFO_BLOCK
```

Sig

Signature of the BTT Index Block data structure. Shall be “BTT_ARENA_INFO00”.

UUID

UUID identifying this BTT instance. A new UUID is created each time the initial BTT Arenas are written. This value shall be identical across all BTT Info Blocks within all arenas within a namespace.

ParentUuid

UUID of containing namespace, used when validating the BTT Info Block to ensure this instance of the BTT layout is intended for the current surrounding namespace, and not left over from a previous namespace that used the same area of the media. This value shall be identical across all BTT Info Blocks within all arenas within a namespace.

Flags

Boolean attributes of this BTT Info Block. See the additional description below on the use of the flags. The following values are defined:

EFI_BTT_INFO_BLOCK_FLAGS_ERROR - The BTT Arena is in the error state. When a BTT implementation discovers issues such as inconsistent metadata or lost metadata due to unrecoverable media errors, the error bit for the associated arena shall be set. See the BTT Theory of Operation section regarding handling of EFI_BTT_INFO_BLOCK_FLAGS_ERROR.

Major

Major version number. Currently at version 2. This value shall be identical across all BTT Info Blocks within all arenas within a namespace.

Minor

Minor version number. Currently at version 0. This value shall be identical across all BTT Info Blocks within all arenas within a namespace.

ExternalLbaSize

Advertised LBA size in bytes. I/O requests shall be in this size chunk. This value shall be identical across all BTT Info Blocks within all arenas within a namespace.

ExternalNLba

Advertised number of LBAs in this arena. The sum of this field, across all BTT Arenas, is the total number of available LBAs in the namespace.

InternalLbaSize

Internal LBA size shall be greater than or equal to ExternalLbaSize and shall not be smaller than 512 bytes. Each block in the arena data area is this size in bytes and contains exactly one block of data. Optionally, this may be larger than the **ExternalLbaSize** due to alignment padding between LBAs. This value shall be identical across all BTT Info Blocks within all arenas within a namespace.

InternalNLba

Number of internal blocks in the arena data area. This shall be equal to **ExternalNLba + NFree** because each internal lba is either mapped to an external lba or shown as free in the flog.

NFree

Number of free blocks maintained for writes to this arena. **NFree** shall be equal to **InternalNLba – ExternalNLba**. This value shall be identical across all BTT Info Blocks within all arenas within a namespace.

InfoSize

The size of this info block in bytes. This value shall be identical across all BTT Info Blocks within all arenas within a namespace.

NextOff

Offset of next arena, relative to the beginning of this arena. An offset of 0 indicates that no arenas follow the current arena. This field is provided for convience as the start of each arena can be calculated from the size of the namespace as described in the **Theory of Operation – Validating BTT Arenas** at start-up description. This value shall be identical in the primary and backup BTT Info Blocks within an arena.

DataOff

Offset of the data area for this arena, relative to the beginning of this arena. The internal-LBA number zero lives at this offset. This value shall be identical in the primary and backup BTT Info Blocks within an arena.

MapOff

Offset of the map for this arena, relative to the beginning of this arena. This value shall be identical in the primary and backup BTT Info Blocks within an arena.

FlogOff

Offset of the flog for this arena, relative to the beginning of this arena. This value shall be identical in the primary and backup BTT Info Blocks within an arena.

InfoOff

Offset of the backup copy of this arena's info block, relative to the beginning of this arena. This value shall be identical in the primary and backup BTT Info Blocks within an arena.

Reserved

Shall be zero.

Checksum

64-bit *Fletcher64* checksum of all fields. This field is considered as containing zero when the checksum is computed.

BTT Info Block Description

The existence of a valid BTT Info Block is used to determine whether a namespace is used as a BTT block device.

Each BTT Arena contains two BTT Info Blocks, a primary copy at the beginning of the BTT Arena, at address offset 0 , and ends with an identical backup BTT Info Block, in the highest block available in the arena aligned on a EFI_BTT_ALIGNMENT boundary. When writing the BTT layout, implementations shall write out the info blocks from the highest arena to the lowest, writing the backup info block and other BTT data structures before writing the primary info block. Writing the layout in this manner shall ensure that a valid BTT layout is only detected after the entire layout has been written.

6.2.2 BTT Map Entry

```
typedef struct _EFI_BTT_MAP_ENTRY {
  UINT32    PostMapLba : 30;
  UINT32    Error : 1;
  UINT32    Zero : 1;
}   EFI_BTT_MAP_ENTRY ;
```

PostMapLba

Post-map LBA number (block number in this arena's data area)

Error

When set and **Zero** is not set, reads on this block return an error. Writes to this block clear this flag.

Zero

When set and **Error** is not set, reads on this block return a full block of zeros. Writes to this block clear this flag.

BTT Map Description

The BTT Map area maps an LBA that indexes into the arena, to its actual location. The BTT Map is located as high as possible in the arena, after room for the backup info block and flog (and any required alignment) has been taken into account. The terminology *pre-map LBA* and *post-map LBA* is used to describe the input and output values of this mapping.

The BTT Map area is indexed by the pre-map LBA and each entry in the map contains the 30 bit post-map LBA and bits to indicate if there is an error or if LBA contains zeroes (see EFI_BTT_MAP_ENTRY).

The **Error** and **Zero** bits indicate conditions that cannot both be true at the same time, so that combination is used to indicate a *normal* map entry, where no error or zeroed block is indicated. The error condition is indicated only when the **Error** bit is set and the **Zero** bit is clear, with similar logic for the zero block condition. When neither condition is indicated, both **Error** and **Zero** are set to indicate a map entry in its normal, non-error state. This leaves the case where both **Error** and **Zero** are bits are zero, which is the initial state of all map entries when the BTT layout is first written. Both bits zero means that the map entry contains the initial *identity* mapping where the pre-map LBA is mapped to the same post-map LBA. Defining the map this way allows an implementation to leverage the case where the initial contents of the namespace is known to be zero, requiring no writes to the map when writing the layout. This can greatly improve the layout time since the map is the largest BTT data structure written during layout.

6.2.3 BTT Flog

```
// Alignment of each flog structure
#define EFI_BTT_FLOG_ENTRY_ALIGNMENT 64

typedef struct _EFI_BTT_FLOG {
  UINT32    Lba0;
  UINT32    OldMap0;
  UINT32    NewMap0;
  UINT32    Seq0;
  UINT32    Lba1;
  UINT32    OldMap1;
  UINT32    NewMap1;
  UINT32    Seq1;
} EFI_BTT_FLOG
```

lba0

Last pre-map LBA written using this flog entry. This value is used as an index into the BTT Map when updating it to complete the transaction.

OldMap0

Old post-map LBA. This is the old entry in the map when the last write using this flog entry occurred. If the transaction is complete, this LBA is now the free block associated with this flog entry.

NewMap0

New post-map LBA. This is the block allocated when the last write using this flog entry occurred. By definition, a write transaction is complete if the BTT Map entry contains this value.

Seq0

The **Seq0** field in each flog entry is used to determine which set of fields is newer between the two sets (Lba0, OldMap0, NewMpa0, Seq0 vs Lba1, Oldmap1, NewMap1, Seq1). Updates to a flog entry shall always be made to the older set of fields and shall be implemented carefully so that the **Seq0** bits are only written after the other fields are known to be committed to persistence. The figure below shows the progression of the **Seq0** bits over time, where the newer entry is indicated by a value that is clockwise of the older value.

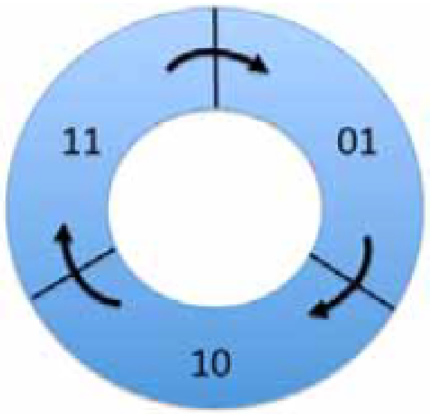

Fig. 6.3: **Cyclic Sequence Numbers for Flog Entries**

BTT Flog Description

The BTT Flog is so named to illustrate that it is both a free list and a log, rolled into one data structure. The Flog size is determined by the **NFree** field in the BTT Info Block which determines how many of these flog entries there are. The flog location is the highest address in the arena after space for the backup info block and alignment requirements have been taken in account.

6.2.4 BTT Data Area

Starting from the low address to high, the BTT Data Area starts immediately after the BTT Info Block and extends to the beginning of the BTT Map data structure. The number of internal data blocks that can be stored in an arena is calculated by first calculating the necessary space required for the BTT Info Blocks, map, and flog (plus any alignment required), subtracting that amount from the total arena size, and then calculating how many blocks fit into the resulting space.

6.2.5 NVDIMM Label Protocol Address Abstraction Guid

This version of the BTT layout and behavior is collectively described by the AddressAbstractionGuid in the UEFI NVDIMM Label protocol section utilizing this GUID:

```
#define EFI_BTT_ABSTRACTION_GUID \
  {0x18633bfc,0x1735,0x4217,
    {0x8a,0xc9,0x17,0x23,0x92,0x82,0xd3,0xf8}
```

6.3 BTT Theory of Operation

This section outlines the theory of operation for the BTT and describes the responsibilities that any software implementation shall follow.

A specific instance of the BTT layout depends on the size of the namespace and three administrative choices made at the time the initial layout is created:

- **ExternalLbaSize**: the desired block size
- **InternalLbaSize**: the block size with any internal padding
- **NFree**: the number of concurrent writes supported by the layout

The BTT data structures do not support an **InternalLbaSize** smaller than 512 bytes, so if **ExternalLbaSize** is smaller than 512 bytes, the **InternalLbaSize** shall be rounded up to 512. For performance, the **InternalLbaSize** may also include some padding bytes. For example, a BTT layout supporting 520-byte blocks may use 576-byte blocks internally in order to round up the size to a multiple of a 64-byte cache line size. In this example, the **ExternalLbaSize**, visible to software above the BTT software, would be 520 bytes, but the **InternalLbaSize** would be 576 bytes.

Once these administrative choices above are determined, the namespace is divided up into *arenas*, as described in the **BTT Arenas** section, where each arena uses the same values for **ExternalLbaSize**, **InternalLbaSize**, and **Nfree**.

6.3.1 BTT Arenas

In order to reduce the size of BTT metadata and increase the possibility of concurrent updates, the BTT layout in a namespace is divided into *arenas*. An arena cannot be larger than 512GiB or smaller than 16MiB. A namespace is divided into as many 512GiB arenas that shall fit, starting from offset zero and packed together without padding, followed by one arena smaller than 512GiB if the remaining space is at least 16MiB. The smaller area size is rounded down to be a multiple of EFI_BTT_ALIGNMENT if necessary. Because of these rules, the location and size of every BTT Arena in a namespace can be determined from the namespace size.

Within an arena, the amount of space used for the Flog is **NFree** times the amount of space required for each Flog entry. Flog entries shall be aligned on 64-byte boundaries. In addition, the full BTT Flog table shall be aligned on a EFI_BTT_ALIGNMENT boundary and have a size that is padded to be multiple of EFI_BTT_ALIGNMENT. In summary, the space in an arena taken by the Flog is:

```
FlogSize = roundup(NFree * roundup(sizeof(EFI_BTT_FLOG),
EFI_BTT_FLOG_ENTRY_ALIGNMENT), EFI_BTT_ALIGNMENT)
```

Within an arena, the amount of space available for data blocks and the associated Map is the arena size minus the space used for the BTT Info Blocks and the Flog:

```
DataAndMapSize = ArenaSize - 2 * sizeof(EFI_BTT_INFO_BLOCK) - FlogSize
```

Within an arena, the number of data blocks is calculated by dividing the available space, DataAndMapSize, by the **InternalLbaSize** plus the map overhead required for each block, and rounding down the result to ensure the data area is aligned on a EFI_BTT_ALIGNMENT boundary:

```
InternalNLba = (DataAndMapSize - EFI_BTT_ALIGNMENT) / (InternalLbaSize +
sizeof(EFI_BTT_MAP_ENTRY)
```

With the InternalNLba value known, the calculation for the number of external LBAs subtracts off NFree for the pool of unadvertised free blocks:

```
ExternalNLba = InternalNLba - Nfree
```

Within an arena, the number of bytes required for the BTT Map is one entry for each external LBA, plus any alignment required to maintain an alignment of EFI_BTT_ALIGNMENT for the entire map:

```
MapSize = roundup(ExternalNLba * sizeof(EFI_BTT_MAP_ENTRY),
EFI_BTT_ALIGNMENT)
```

The number of concurrent writes allowed for an arena is based on the **NFree** value chosen at BTT layout time. For example, choosing **NFree** of 256 means the BTT Arena shall have 256 free blocks to use for in-flight write operations. Since BTT Arenas each have **NFree** free blocks, the number of concurrent writes allowed in a namespace may be larger when there are multiple arenas and the writes are spread out between multiple arenas.

6.3.2 Atomicity of Data Blocks in an Arena

The primary reason for the BTT is to provide failure atomicity when writing data blocks, so that any write of a single block cannot be torn by interruptions such as power loss. The BTT provides this by maintaining a pool of free blocks which are not part of the capacity advertised to software layers above the BTT software. The BTT Data Area is large enough to hold the advertised capacity as well as the pool of free blocks. The BTT software manages the blocks in the BTT Data Area as a list of *internal* LBAs, which are block numbers only visible internally to the BTT software. The block numbers that make up the advertised capacity are known as *external* LBAs, and at any given point in time, each one of those external LBAs is mapped by the BTT Map to one of the blocks in the BTT Data Area. Each block write done by the BTT software starts by allocating one of the free blocks, writing the data to it, and only when that block is fully persistent (including any flushes required), are steps taken to make that block active, as outlined in the **BTT Theory of Operations - Write Path** section.

The BTT Flog (a combination of a free list and a log) is at the heart of the atomic updates when writing blocks. The "quiet" state of a BTT Flog, when no in-flight writes are happening and no recovery steps are outstanding, is that the **NFree** free blocks currently available for writes are contained in the OldMap fields in the Flog entries. A write shall use one of those Flog entries to find a free block to write to, and then the Lba and NewMap fields in the Flog are used as a *write-ahead-log* for the BTT Map update when the data portion of the write is complete, as described in the **Validating the Flog at start-up** section.

It is up to run-time logic in the BTT software to ensure that only one Flog entry is in use at a time, and that any reads still executing on the block indicated by the OldMap entry have finished before starting a write using that block.

6.3.3 Atomicity of BTT Data Structures

Byte-addressable persistent media may not support atomic updates larger than 8-bytes, so any data structure larger than 8-bytes in the BTT uses software-implemented atomicity for updates. Note that 8-byte write atomicity, meaning an 8-byte store to the persistent media cannot be torn by interruptions such as power failures, is a minimal requirement for using the BTT described in this document.

There are four types of data structures in the BTT:

- The BTT Info Blocks
- The BTT Map
- The BTT Flog
- The BTT Data Area

The BTT Map entries are 4-bytes in size, and so can be updated atomically with a single store instruction. All other data structures are updated by following the rules described in this document, which update an inactive version of the data structure first, followed by steps to make it active atomically.

For the BTT Info Blocks, atomicity is provided by always writing the backup Info block first, and only after that update is fully persistent (the block checksums correctly), is the primary BTT Info Block updated as described in the **Writing the initial BTT layout** section. Recovery from an interrupted update is provided by checking the primary Info block's checksum on start-up, and if it is bad, copying the backup Info block to the primary to complete the interrupted update as described in the **Validating BTT Arenas** at start-up section.

For the BTT Flog, each entry is double-sized, with two complete copies of every field (Lba, OldMap, NewMap, Seq). The active entry has the higher Seq number, so updates always write to the inactive fields, and once those fields are fully persistent, the Seq field for the inactive entry is updated to make it become the active entry atomically. This is described in the **Validating the Flog at start-up** section.

For the BTT Data Area, all block writes can be thought of as *allocating writes*, where an inactive block is chosen from the free list maintained by the Flog, and only after the new data written to that block is fully persistent, that block is made active atomically by updating the Flog and Map entries as described in the **Write Path** section.

6.3.4 Writing the Initial BTT layout

The overall layout of the BTT relies on the fact that all arenas shall be 512GiB in size, except the last arena which is a minimum of 16MiB. Initializing the BTT on-media structures only happens once in the lifetime of a BTT, when it is created. This sequence assumes that software has determined that new BTT layout needs to be created and the total raw size of the namespace is known.

Immediately before creating a new BTT layout, the UUID of the surrounding namespace may be updated to a newly-generated UUID. This optional step, depending on the needs of a BTT software implementation, has the effect of invalidating any previous BTT Info Blocks in the namespace and ensuring the detection of an invalid layout if the BTT layout creation process is interrupted. This detection works because the parent UUID field

The on-media structures in the BTT layout may be written out in any order except for the BTT Info Blocks, which shall be written out as the last step of the layout, starting from the last arena (highest offset in the namespace) to the first arena (lowest offset in the namespace), writing the backup BTT Info Block in each arena first, then writing the primary BTT Info block for that arena second. This allows the detection of an incomplete BTT layout when the algorithm in the **Validating BTT Arenas at start-up** section is executed.

Since the number of internal LBAs for an arena exceeds the number of external LBAs by **NFree**, there are enough internal LBA numbers to fully initialize the BTT Map as well as the BTT Flog, where the BTT Flog is initialized with the **NFree** highest internal LBA numbers, and the rest are used in the BTT Map.

The BTT Map in each arena is initialized to zeros. Zero entries in the map indicate the *identity* mapping of all pre-map LBAs to the corresponding post-map LBAs. This uses all but **NFree** of the internal LBAs, leaving **Nfree** of them for the BTT Flog.

The BTT Flog in each arena is initialized by starting with all zeros for the entire flog area, setting the **Lba0** field in each flog entry to unique pre-map LBAs, zero through **NFree - 1**, and both **OldMap0** and **NewMap0** fields in each flog entry are set to one of the remaining internal LBAs. For example, flog entry zero would have Lba0 set to 0, and **OldMap0** and **NewMap0** both set to the first internal LBA not represented in the map (since there are **ExternalNLba** entries in the map, the next available internal LBA is equal to **ExternalNLba**).

6.3.5 Validating BTT Arenas at start-up

When software prepares to access the BTT layout in a namespace, the first step is to check the BTT Arenas for consistency. Reading and validating BTT Arenas relies on the fact that all arenas shall be 512GiB in size, except the last arena which is a minimum of 16MiB.

The following tests shall pass before software considers the BTT layout to be valid:

- For each BTT Arena:
  - ReadAndVerifyPrimaryBttInfoBlock
    - If the read of the primary BTT Info Block fails, goto ReadAndVerifyBackupBttInfoBlock
    - If the primary BTT Info Block contains an incorrect **Sig** field it is invalid, goto ReadAndVerifyBackupBttInfoBlock
    - If the primary BTT Info Block ParentUuid field does not match the UUID of the surrounding namespace, goto ReadAndVerifyBackupBttInfoBlock
    - If the primary BTT Info Block contains an incorrect **Checksum** it is invalid, goto ReadAndVerifyBackupBttInfoBlock
    - The primary BTT Info Block is valid. Use the **NextOff** field to find the start of the next arena and continue BTT Info Block validation, goto ReadAndVerifyPrimaryBttInfoBlock
  - ReadAndVerifyBackupBttInfoBlock

- Determine the location of the backup BTT Info Block:
  1. All of the arenas shall be the full 512GiB data area size except the last arena which is at least 16MiB.
  2. The backup BTT Info Block is the last EFI_BTT_ALIGNMENT aligned block in the arena.
- If the read of the backup BTT Info Block at the high address of the BTT Arena fails, neither copy could be read, and software shall assume that there is no valid BTT metadata layout for the namespace
- If the backup BTT Info Block contains an incorrect **Sig** field it is invalid, and software shall assume that there is no valid BTT metadata layout for the namespace
- If the backup BTT Info Block ParentUuid field does not match the UUID of the surrounding namespace it is invalid, and software shall assume that there is no valid BTT metadata layout for the namespace
- If the backup BTT Info Block contains an incorrect **Checksum** it is invalid, and software shall assume that there is no valid BTT metadata layout for the namespace
- The backup BTT Info Block is valid. Since the primary copy is bad, software shall copy the contents of the valid backup BTT Info Block down to the primary BTT Info Block before validation of all of the BTT Info Blocks in all of the arenas can complete successfully.

6.3.6 Validating the Flog entries at start-up

After validating the BTT Info Blocks as described in the **Validating BTT Arenas at start-up** section, the next step software shall take is to validate the BTT Flog entries. When blocks of data are being written, as described in the **Write Path** section below, the persistent Flog and Map states are not updated until the free block is written with new data. This ensures a power failure at any point during the data transfer is harmless, leaving the partially written data in a free block that remains free. Once the Flog is updated (made atomic by the Seq bits in the Flog entry), the write algorithm is committed to the update and a power failure from this point in the write flow onwards shall be handled by completing the update to the BTT Map on recovery. The Flog contains all the information required to complete the Map entry update.

Note that the Flog entry recovery outlined here is intended to happen single-threaded, on an *inactive* BTT (before the BTT block namespace is allowed to accept I/O requests). The maximum amount of time required for recovery is determined by **NFree**, but is only a few loads and a single store (and the corresponding cache flushes) for each incomplete write discovered.

The following steps are executed for each flog entry in each arena, to recover any interrupted writes and to verify the flog entries are consistent at start up. Any consistency issues found during these steps results in setting the error state (EFI_BTT_INFO_BLOCK_FLAGS_ERROR) for the arena and terminates the flog validation process for this arena.

1. The **Seq0** and **Seq1** fields are examined for the flog entry. If both fields are zero, or both fields are equal to each other, the flog entry is inconsistent. Otherwise, the higher Seq field indicates which set of flog fields to use for the next steps (**Lba0**, **OldMap0**, **NewMap0**, versus **Lba1**, **OldMap1**, **NewMap1**). From this point on in this section, the chosen fields are referenced as Lba, OldMap, and NewMap.
2. If OldMap and NewMap are equal, this is a flog entry that was never used since the initial layout of the BTT was created.
3. The Lba field is checked to ensure it is a valid pre-map LBA (in the range zero to **ExternalNLba** – 1). If the check fails, the flog entry is inconsistent.
4. The BTT Map entry corresponding to the Flog entry Lba field is fetched. Since the Map can contain special zero entries to indicate identity mappings, the fetched entry is adjusted to the corresponding internal LBA when a zero is encountered (by interpreting the entry as the same LBA as the Flog entry Lba field).

5. If the adjusted map entry from the previous step does not match the NewMap field in the Flog entry, and it matches the OldMap field, then an interrupted BTT Map update has been detected. The recovery step is to write the NewMap field to the BTT Map entry indexed by the Flog entry Lba field.

6.3.7 Read Path

The following high level sequence describes the steps to read a single block of data while utilizing the BTT as is illustrated in the **Figure: BTT Read Path Overview** below:

1. If EFI_BTT_INFO_BLOCK_FLAGS_ERROR is set in the arena's BTT Info Block, the BTT software may return an error for the read, or an implementation may choose to continue to provide read-only access and continue these steps.
2. Use the external LBA provided with the read operation to determine which BTT Arena to access. Starting from the first arena (lowest offset in the namespace), and looping through the arena in order, the **ExternalNLba** field in the BTT Info Block describes how many exernal LBAs are in that area. Once the correct arena is identified, the external LBAs contained in the lower, skipped, arenas are subtracted from the provided LBA to obtain the pre-map LBA for the selected arena.
3. Use the pre-map LBA to index into the arena's BTT Map and the map entry.
4. If both the **Zero** and **Error** bits are set in the map entry, this indicates a normal entry. The PostMapLba field in the Map entry is used to index into the arena Data Area by multiplying it by the **InternalLbaSize** and adding the result to the **DataOff** field from the arena's BTT Info Block. This provides the location of the data in the arena and software then copies **ExternalLbaSize** bytes into the provided buffer to satisfy the read request.
5. Otherwise, if only the **Error** bit is set in the map entry, a read error is returned.
6. Otherwise, if only the **Zero** bit is set in the map entry, a block of **ExternalLbaSize** bytes of zeros is copied into the provided buffer to satisfy the read request.
7. Finally, if both **Zero** and **Error** bits are clear, this the initial identity mapping and the pre-map LBA is used to index into the arena Data Area by multiplying it by the **InternalLbaSize** and adding the result to the **DataOff** field from the arena's BTT Info Block. This provides the location of the data in the arena and software then copies **ExternalLbaSize** bytes into the provided buffer to satisfy the read request.

6.3.8 Write Path

The following high level sequence describes the steps to write a single block of data while utilizing the BTT as is illustrated in the **Figure: BTT Write Path Overview below**:

1. If EFI_BTT_INFO_BLOCK_FLAGS_ERROR is set in the arena's BTT Info Block, the BTT software shall return an error for the write.
2. Use the external LBA provided with the write operation to determine which BTT Arena to access. Starting from the first arena (lowest offset in the namespace), and looping through the arena in order, the **ExternalNLba** field in the BTT Info Block describes how many exernal LBAs are in that area. Once the correct arena is identified, the external LBAs contained in the lower, skipped, arenas are subtracted from the provided LBA to obtain the pre-map LBA for the selected arena.
3. The BTT software allocates one of the Flog entries in the arena to be used for this write. The Flog entry shall not be shared by multiple concurrent writes. The exact method for managing the exclusive use of the Flog entries is BTT software implementation-dependent. There's no on-media indication of whether a Flog entry is currently allocated to a write request or not. Note that the free block tracked by the Flog entry in the OldMap field, may still have reads from relatively slow threads operating on it. The BTT software implementation shall ensure any such reads have completed before moving to the next step.

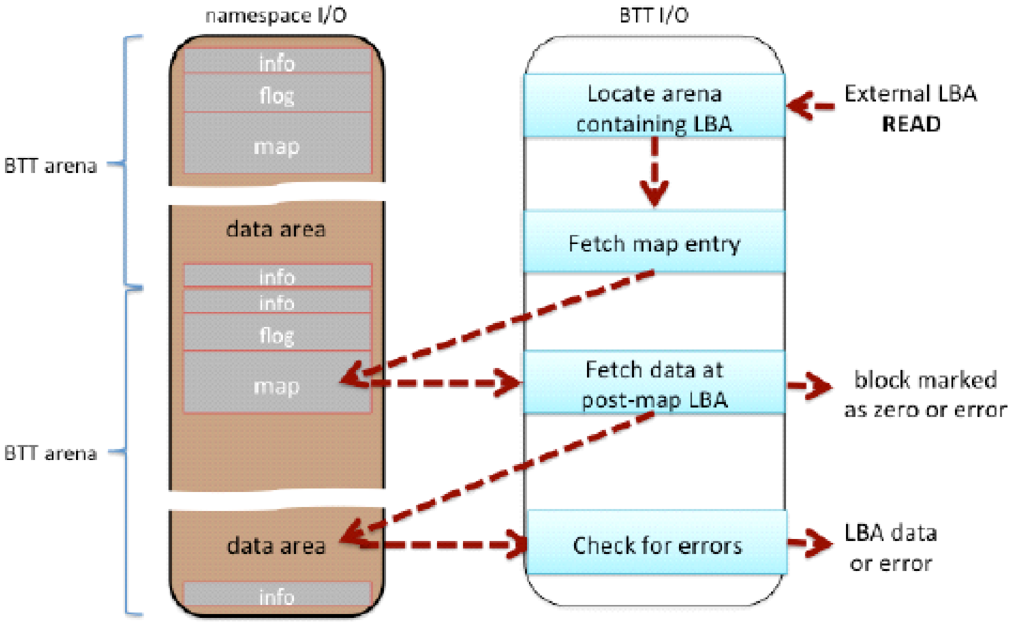

Fig. 6.4: BTT Read Path Overview

4. Lock out access to the BTT Map area associated with the pre-map LBA for the next three steps. The granularity of the locking is implementation-dependent; an implementation may choose to lock individual Map entries, lock the entire BTT Map, or something in-between.
5. Use the pre-map LBA to index into the arena's BTT Map and fetch the old map entry.
6. Update the Flog entry by writing the inactive set of Flog fields (the lower Seq number). First, update the Lba, OldMap, and NewMap fields with the pre-map LBA, old Map entry, and the free block chosen above, respectively. Once those fields are fully persistent (with any required flushes completed), the Seq field is updated to make the new fields active. This update of the Seq field commits the write - before this update, the write shall not take place if the operation is interrupted. After the Seq field is updated, the write shall take place even if the operation is interrupted because the Map update in the next step shall take place during the BTT recovery that happens on start-up.
7. Update the Map entry with the free block chosen above.
8. Drop the map lock acquired in step 4 above. The write request is now satisfied.

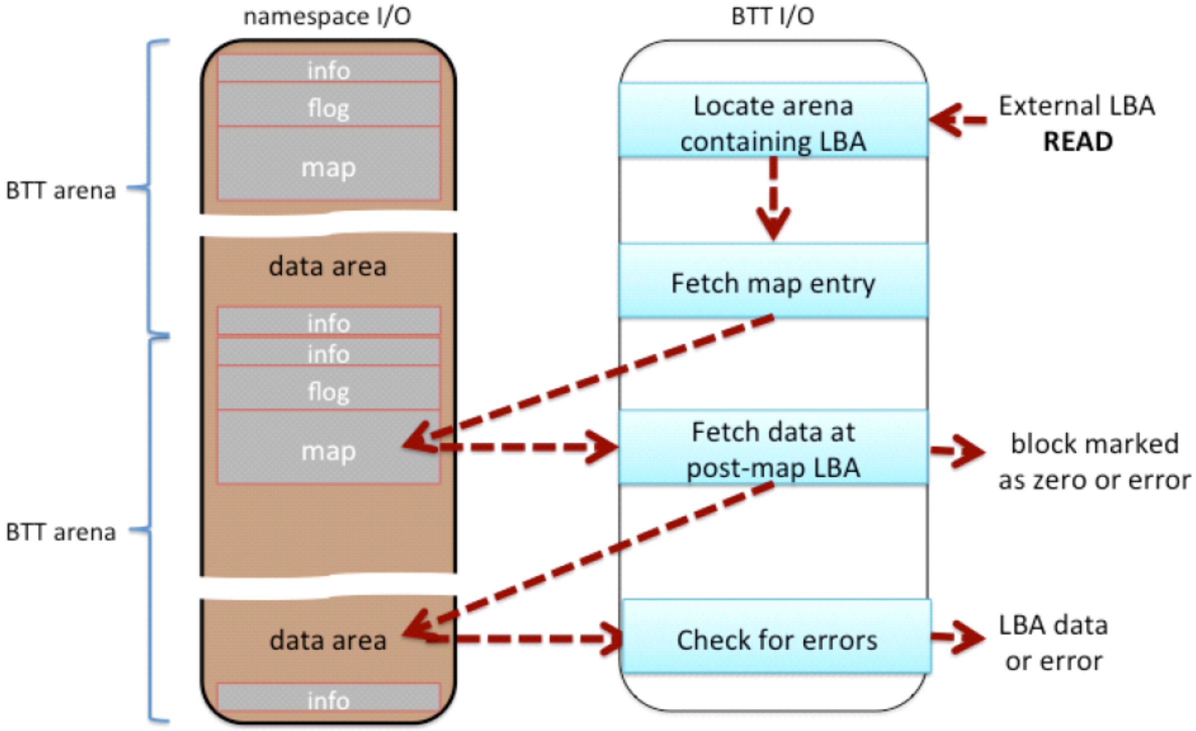

Fig. 6.5: BTT Write Path Overview

CHAPTER SEVEN

SERVICES — BOOT SERVICES

This section discusses the fundamental boot services that are present in a UEFI compliant system. The services are defined by interface functions that may be used by code running in the UEFI environment. Such code may include protocols that manage device access or extend platform capability, as well as applications running in the preboot environment, and OS loaders.

Two types of services apply in an compliant system:

Boot Services

Functions that are available *before* a successful call to *EFI_BOOT_SERVICES.ExitBootServices()*. These functions are described in this section.

Runtime Services

Functions that are available *before and after* any call to ExitBootServices(). These functions are described in *Services — Runtime Services* .

During boot, system resources are owned by the firmware and are controlled through boot services interface functions. These functions can be characterized as "global" or "handle-based." The term "global" simply means that a function accesses system services and is available on all platforms (since all platforms support all system services). The term "handle-based" means that the function accesses a specific device or device functionality and may not be available on some platforms (since some devices are not available on some platforms). Protocols are created dynamically. This section discusses the "global" functions and runtime functions; subsequent sections discuss the "handle-based."

UEFI applications (including UEFI OS loaders) must use boot services functions to access devices and allocate memory. On entry, an Image is provided a pointer to a system table which contains the Boot Services dispatch table and the default handles for accessing the console. All boot services functionality is available until a UEFI OS loader loads enough of its own environment to take control of the system's continued operation and then terminates boot services with a call to ExitBootServices().

In principle, the ExitBootServices() call is intended for use by the operating system to indicate that its loader is ready to assume control of the platform and all platform resource management. Thus boot services are available up to this point to assist the UEFI OS loader in preparing to boot the operating system. Once the UEFI OS loader takes control of the system and completes the operating system boot process, only runtime services may be called. Code other than the UEFI OS loader, however, may or may not choose to call ExitBootServices(). This choice may in part depend upon whether or not such code is designed to make continued use of boot services or the boot services environment.

The rest of this section discusses individual functions. Global boot services functions fall into these categories:

- Event, Timer, and Task Priority Services *Event, Timer, and Task Priority Services*
- Memory Allocation Services *Memory Allocation Services*
- Protocol Handler Services *Protocol Handler Services*
- Image Services *Image Services*

7.1 Event, Timer, and Task Priority Services

The functions that make up the Event, Timer, and Task Priority Services are used during preboot to create, close, signal, and wait for events; to set timers; and to raise and restore task priority levels. See the following table for details.

Table 7.1: Event, Timer, and Task Priority Functions

Name	Type	Description
CreateEvent	Boot	Creates a general-purpose event structure
CreateEventEx	Boot	Creates an event structure as part of an event group
CloseEvent	Boot	Closes and frees an event structure
SignalEvent	Boot	Signals an event
WaitForEvent	Boot	Stops execution until an event is signaled
CheckEvent	Boot	Checks whether an event is in the signaled state
SetTimer	Boot	Sets an event to be signaled at a particular time
RaiseTPL	Boot	Raises the task priority level
RestoreTPL	Boot	Restores/lowers the task priority level

Execution in the boot services environment occurs at different task priority levels, or TPLs. The boot services environment exposes only three of these levels to UEFI applications and drivers (see table below: *TPL Usage*)

- **TPL_APPLICATION** — the lowest priority level
- **TPL_CALLBACK** — an intermediate priority level{
- **TPL_NOTIFY** — the highest priority level

Tasks that execute at a higher priority level may interrupt tasks that execute at a lower priority level. For example, tasks that run at the TPL_NOTIFY level may interrupt tasks that run at the TPL_APPLICATION or TPL_CALLBACK level. While TPL_NOTIFY is the highest level exposed to the boot services applications, the firmware may have higher task priority items it deals with. For example, the firmware may have to deal with tasks of higher priority like timer ticks and internal devices. Consequently, there is a fourth TPL, TPL_HIGH_LEVEL {link needed}, designed for use exclusively by the firmware.

The intended usage of the priority levels is shown in the TPL Usage table below, from the lowest level (TPL_APPLICATION) to the highest level (TPL_HIGH_LEVEL). As the level increases, the duration of the code and the amount of blocking allowed decrease. Execution generally occurs at the TPL_APPLICATION level. Execution occurs at other levels as a direct result of the triggering of an event notification function(this is typically caused by the signaling of an event). During timer interrupts, firmware signals timer events when an event's "trigger time" has expired. This allows event notification functions to interrupt lower priority code to check devices (for example). The notification function can signal other events as required. After all pending event notification functions execute, execution continues at the TPL_APPLICATION level.

Table 7.2: TPL Usage

Task Priority Level	Usage
TPL_APPLICATION	This is the lowest priority level. It is the level of execution which occurs when no event notifications are pending and which interacts with the user. User I/O (and blocking on User I/O) can be performed at this level. The boot manager executes at this level and passes control to other UEFI applications at this level.
TPL_CALLBACK	Interrupts code executing below TPL_CALLBACK level. Long term operations (such as file system operations and disk I/O) can occur at this level.

continues on next page

Table 7.2 – continued from previous page

TPL_NOTIFY	Interrupts code executing below TPL_NOTIFY level. Blocking is not allowed at this level. Code executes to completion and returns. If code requires more processing, it needs to signal an event to wait to obtain control again at whatever level it requires. This level is typically used to process low level IO to or from a device.
(Firmware Interrupts)	This level is internal to the firmware. It is the level at which internal interrupts occur. Code running at this level interrupts code running at the TPL_NOTIFY level (or lower levels). If the interrupt requires extended time to complete, firmware signals another event (or events) to perform the longer term operations so that other interrupts can occur.
TPL_HIGH_LEVEL	Interrupts code executing below TPL_HIGH_LEVEL This is the highest priority level. It is not interruptible (interrupts are disabled) and is used sparingly by firmware to synchronize operations that need to be accessible from any priority level. For example, it must be possible to signal events while executing at any priority level. Therefore, firmware manipulates the internal event structure while at this priority level.

Executing code can temporarily raise its priority level by calling the *EFI_BOOT_SERVICES.RaiseTPL()* function. Doing this masks event notifications from code running at equal or lower priority levels until the *EFI_BOOT_SERVICES.RestoreTPL()* function is called to reduce the priority to a level below that of the pending event notifications. There are restrictions on the TPL levels at which many UEFI service functions and protocol interface functions can execute. *TPL Restrictions* summarizes the restrictions.

7.1.1 EFI_BOOT_SERVICES.CreateEvent()

Summary

Creates an event.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_CREATE_EVENT) (
   IN UINT32                  Type,
   IN EFI_TPL                 NotifyTpl,
   IN EFI_EVENT_NOTIFY        NotifyFunction, OPTIONAL
   IN VOID                    *NotifyContext, OPTIONAL
   OUT EFI_EVENT              *Event
   );
```

Parameters

Type

The type of event to create and its mode and attributes. The *#define* statements in “Related Definitions” can be used to specify an event’s mode and attributes.

NotifyTpl
The task priority level of event notifications, if needed. See *EFI_BOOT_SERVICES.RaiseTPL()* .

NotifyFunction
Pointer to the event's notification function, if any. See "Related Definitions."

NotifyContext
Pointer to the notification function's context; corresponds to parameter *Context* in the notification function.

Event
Pointer to the newly created event if the call succeeds; undefined otherwise.

Related Definitions

```
//***************************************************
// EFI_EVENT
//******************************************************
typedef VOID *EFI_EVENT

//******************************************************
// Event Types
//******************************************************
// These types can be "ORed" together as needed - for example,
// EVT_TIMER might be "Ored" with EVT_NOTIFY_WAIT or
// EVT_NOTIFY_SIGNAL.
#define EVT_TIMER                            0x80000000
#define EVT_RUNTIME                          0x40000000

#define EVT_NOTIFY_WAIT                      0x00000100
#define EVT_NOTIFY_SIGNAL                    0x00000200

#define EVT_SIGNAL_EXIT_BOOT_SERVICES        0x00000201
#define EVT_SIGNAL_VIRTUAL_ADDRESS_CHANGE    0x60000202
```

EVT_TIMER
The event is a timer event and may be passed to *EFI_BOOT_SERVICES.SetTimer()* . Note that timers only function during boot services time.

EVT_RUNTIME
The event is allocated from runtime memory. If an event is to be signaled after the call to *EFI_BOOT_SERVICES.ExitBootServices()* the event's data structure and notification function need to be allocated from runtime memory. For more information, see *SetVirtualAddressMap()* .

EVT_NOTIFY_WAIT
If an event of this type is not already in the signaled state, then the event's *NotificationFunction* will be queued at the event's *NotifyTpl* whenever the event is being waited on via *EFI_BOOT_SERVICES.WaitForEvent()* or *EFI_BOOT_SERVICES.CheckEvent()* .

EVT_NOTIFY_SIGNAL
The event's *NotifyFunction* is queued whenever the event is signaled.

EVT_SIGNAL_EXIT_BOOT_SERVICES
This event is of type EVT_NOTIFY_SIGNAL. It should not be combined with any other event types. This event type is functionally equivalent to the EFI_EVENT_GROUP_EXIT_BOOT_SERVICES event group. Refer to EFI_EVENT_GROUP_EXIT_BOOT_SERVICES event group description in *EFI_BOOT_SERVICES.CreateEventEx()* section below for additional details.

EVT_SIGNAL_VIRTUAL_ADDRESS_CHANGE
The event is to be notified by the system when SetVirtualAddressMap() is performed. This event type is a

composite of EVT_NOTIFY_SIGNAL, EVT_RUNTIME, and EVT_RUNTIME_CONTEXT and should not be combined with any other event types.

```
//*******************************************************\*
// EFI_EVENT_NOTIFY
//*******************************************************\*
typedef
VOID
(EFIAPI *EFI_EVENT_NOTIFY) (
  IN EFI_EVENT          Event,
  IN VOID              *Context
   );
```

Event

Event whose notification function is being invoked.

Context

Pointer to the notification function's context, which is implementation-dependent. *Context* corresponds to *NotifyContext* in *EFI_BOOT_SERVICES.CreateEventEx()* .

Description

The *CreateEvent()* function creates a new event of type *Type* and returns it in the location referenced by *Event*. The event's notification function, context, and task priority level are specified by *NotifyFunction*, *NotifyContext*, and *NotifyTpl*, respectively.

Events exist in one of two states, "waiting" or "signaled." When an event is created, firmware puts it in the "waiting" state. When the event is signaled, firmware changes its state to "signaled" and, if *EVT_NOTIFY_SIGNAL* is specified, places a call to its notification function in a FIFO queue. There is a queue for each of the "basic" task priority levels defined in *Event, Timer, and Task Priority Services* (*TPL_CALLBACK*, and *TPL_NOTIFY*). The functions in these queues are invoked in FIFO order, starting with the highest priority level queue and proceeding to the lowest priority queue that is unmasked by the current TPL. If the current TPL is equal to or greater than the queued notification, it will wait until the TPL is lowered via *EFI_BOOT_SERVICES.RestoreTPL()* .

In a general sense, there are two "types" of events, synchronous and asynchronous. Asynchronous events are closely related to timers and are used to support periodic or timed interruption of program execution. This capability is typically used with device drivers. For example, a network device driver that needs to poll for the presence of new packets could create an event whose type includes *EVT_TIMER* and then call the :ref:` EFI_BOOT_SERVICES.SetTimer` function. When the timer expires, the firmware signals the event.

Synchronous events have no particular relationship to timers. Instead, they are used to ensure that certain activities occur following a call to a specific interface function. One example of this is the cleanup that needs to be performed in response to a call to the *EFI_BOOT_SERVICES.ExitBootServices()* function. *ExitBootServices()* can clean up the firmware since it understands firmware internals, but it cannot clean up on behalf of drivers that have been loaded into the system. The drivers have to do that themselves by creating an event whose type is EVT_SIGNAL_EXIT_BOOT_SERVICES and whose notification function is a function within the driver itself. Then, when ExitBootServices() has finished its cleanup, it signals each event of type EVT_SIGNAL_EXIT_BOOT_SERVICES.

Another example of the use of synchronous events occurs when an event of type EVT_SIGNAL_VIRTUAL_ADDRESS_CHANGE is used in conjunction with the *SetVirtualAddressMap()* .

The EVT_NOTIFY_WAIT and EVT_NOTIFY_SIGNAL flags are exclusive. If neither flag is specified, the caller does not require any notification concerning the event and the *NotifyTpl*, *NotifyFunction*, and *NotifyContext* parameters are ignored. If EVT_NOTIFY_WAIT is specified and the event is not in the signaled state, then the EVT_NOTIFY_WAIT notify function is queued whenever a consumer of the event is waiting for the event (via EFI_BOOT_SERVICES.WaitForEvent() or EFI_BOOT_SERVICES.CheckEvent()). If the EVT_NOTIFY_SIGNAL flag is specified then the event's notify function is queued whenever the event is signaled.

NOTE: *Because its internal structure is unknown to the caller*, Event *cannot be modified by the caller. The only way to manipulate it is to use the published event interfaces.*

Status Codes Returned

EFI_SUCCESS	The event structure was created.
EFI_INVALID_PARAMETER	One of the parameters has an invalid value.
EFI_INVALID_PARAMETER	*Event* is NULL.
EFI_INVALID_PARAMETER	*Type* has an unsupported bit set.
EFI_INVALID_PARAMETER	*Type* has both EVT_NOTIFY_SIGNAL and EVT_NOTIFY_WAIT set.
EFI_INVALID_PARAMETER	*Type* has either EVT_NOTIFY_SIGNAL or EVT_NOTIFY_WAIT set and - *NotifyFunction* is NULL.
EFI_INVALID_PARAMETER	Type has either EVT_NOTIFY_SIGNAL or EVT_NOTIFY_WAIT set and *NotifyTpl* is not a supported TPL level.
EFI_OUT_OF_RESOURCES	The event could not be allocated.

7.1.2 EFI_BOOT_SERVICES.CreateEventEx()

Summary

Creates an event in a group.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_CREATE_EVENT_EX) (
   IN UINT32                  Type,
   IN EFI_TPL                 NotifyTpl,
   IN EFI_EVENT_NOTIFY        NotifyFunction OPTIONAL,
   IN CONST VOID              *NotifyContext OPTIONAL,
   IN CONST EFI_GUID          *EventGroup OPTIONAL,
   OUT EFI_EVENT              *Event
   );
```

Parameters

Type

The type of event to create and its mode and attributes.

NotifyTpl

The task priority level of event notifications, if needed. See *EFI_BOOT_SERVICES.RaiseTPL()* .

NotifyFunction

Pointer to the event's notification function, if any.

NotifyContext

Pointer to the notification function's context; corresponds to parameter *Context* in the notification function.

EventGroup

Pointer to the unique identifier of the group to which this event belongs. If this is NULL, then the function behaves as if the parameters were passed to CreateEvent.

Event

Pointer to the newly created event if the call succeeds; undefined otherwise.

Description

The CreateEventEx function creates a new event of type *Type* and returns it in the specified location indicated by *Event*. The event's notification function, context and task priority are specified by *NotifyFunction, NotifyContext*, and *NotifyTpl*, respectively. The event will be added to the group of events identified by *EventGroup.*

If no group is specified by *EventGroup*, then this function behaves as if the same parameters had been passed to CreateEvent.

Event groups are collections of events identified by a shared EFI_GUID where, when one member event is signaled, all other events are signaled and their individual notification actions are taken (as described in CreateEvent). All events are guaranteed to be signaled before the first notification action is taken. All notification functions will be executed in the order specified by their *NotifyTpl*.

A single event can only be part of a single event group. An event may be removed from an event group by using CloseEvent.

The *Type* of an event uses the same values as defined in CreateEvent except that EVT_SIGNAL_EXIT_BOOT_SERVICES and EVT_SIGNAL_VIRTUAL_ADDRESS_CHANGE are not valid.

If *Type* has EVT_NOTIFY_SIGNAL or EVT_NOTIFY_WAIT, then *NotifyFunction* must be non-NULL and *NotifyTpl* must be a valid task priority level. Otherwise these parameters are ignored.

More than one event of type EVT_TIMER may be part of a single event group. However, there is no mechanism for determining which of the timers was signaled.

Configuration Table Groups

The GUID for a configuration table also defines a corresponding event group GUID with the same value. If the data represented by a configuration table is changed, InstallConfigurationTable() should be called. When InstallConfigurationTable() is called, the corresponding event is signaled. When this event is signaled, any components that cache information from the configuration table can optionally update their cached state.

For example, EFI_ACPI_TABLE_GUID defines a configuration table for ACPI data. When ACPI data is changed, InstallConfigurationTable() is called. During the execution of InstallConfigurationTable(), a corresponding event group with EFI_ACPI_TABLE_GUID is signaled, allowing an application to invalidate any cached ACPI data.

Pre-Defined Event Groups

This section describes the pre-defined event groups used by the UEFI specification.

EFI_EVENT_GROUP_EXIT_BOOT_SERVICES

This event group is notified by the system when ExitBootServices() is invoked after notifying EFI_EVENT_GROUP_BEFORE_EXIT_BOOT_SERVICES event group. This event group is functionally equivalent to the EVT_SIGNAL_EXIT_BOOT_SERVICES flag for the Type argument of CreateEvent. The notification function for this event must comply with the following requirements:

- The notification function is not allowed to use the Memory Allocation Services, or call any functions that use the Memory Allocation Services, because these services modify the current memory map.

Note: *Since consumer of the service does not necessarily knows if the service uses memory allocation services, this requirement is effectively a mandate to reduce usage of any external services (services implemented outside of the driver owning the notification function) to an absolute minimum required to perform an orderly transition to a runtime environment. Usage of the external services may yield unexpected results. Since UEFI specification does not guarantee any given order of notification function invocation, a notification function consuming the service may be invoked before or after the notification function of the driver providing the service. As a result, a service being called by the notification function may exhibit boot time behavior or a runtime behavior (which is undefined for a pure boot services).*

- The notification function must not depend on timer events since timer services will be deactivated before any notification functions are called.

Refer to EFI_BOOT_SERVICES.ExitBootServices() below for additional details.

EFI_EVENT_GROUP_BEFORE_EXIT_BOOT_SERVICES

This event group is notified by the system ExitBootServices() is invoked right before notifying EFI_EVENT_GROUP_EXIT_BOOT_SERVICES event group. The event presents the last opportunity to use firmware interfaces in the boot environment.

The notification function for this event must not depend on any kind of delayed processing (processing that happens in a timer callback beyond the time span of the notification function) because system firmware deactivates timer services right after dispatching handlers for this event group.

Refer to **EFI_BOOT_SERVICES**.ExitBootServices() below for additional details.

EFI_EVENT_GROUP_VIRTUAL_ADDRESS_CHANGE

This event group is notified by the system when SetVirtualAddressMap() is invoked. This is functionally equivalent to the VT_SIGNAL_VIRTUAL_ADDRESS_CHANGE flag for the *Type* argument of CreateEvent.

EFI_EVENT_GROUP_MEMORY_MAP_CHANGE

This event group is notified by the system when the memory map has changed. The notification function for this event should not use Memory Allocation Services to avoid reentrancy complications.

EFI_EVENT_GROUP_READY_TO_BOOT

This event group is notified by the system right before notifying EFI_EVENT_GROUP_AFTER_READY_TO_BOOT event group when the Boot Manager is about to load and execute a boot option or a platform or OS recovery option. The event group presents the last chance to modify device or system configuration prior to passing control to a boot option.

EFI_EVENT_GROUP_AFTER_READY_TO_BOOT

This event group is notified by the system immediately after notifying EFI_EVENT_GROUP_READY_TO_BOOT event group when the Boot Manager is about to load and execute a boot option or a platform or OS recovery option. The event group presents the last chance to survey device or system configuration prior to passing control to a boot option.

EFI_EVENT_GROUP_RESET_SYSTEM

This event group is notified by the system when ResetSystem() is invoked and the system is about to be reset. The event group is only notified prior to ExitBootServices() invocation.

Related Definitions

EFI_EVENT is defined in *CreateEvent*.

EVT_SIGNAL_EXIT_BOOT_SERVICE and *EVT_SIGNAL_VIRTUAL_ADDRESS_CHANGE* are defined in *CreateEvent*.

```
#define EFI_EVENT_GROUP_EXIT_BOOT_SERVICES \

```

(continues on next page)

(continued from previous page)

```
#define EFI_EVENT_GROUP_READY_TO_BOOT \
 {0x7ce88fb3, 0x4bd7, 0x4679, 0x87, 0xa8, 0xa8, 0xd8, 0xde,\
 0xe5,0xd, 0x2b}

define EFI_EVENT_GROUP_AFTER_READY_TO_BOOT \
  { 0x3a2a00ad, 0x98b9, 0x4cdf, { 0xa4, 0x78, 0x70, 0x27, 0x77,
0xf1, 0xc1, 0xb } }

#define EFI_EVENT_GROUP_RESET_SYSTEM \
{ 0x62da6a56, 0x13fb, 0x485a, { 0xa8, 0xda, 0xa3, 0xdd, 0x79, 0x12, 0xcb, 0x6b
 } }
```

Status Codes Returned

EFI_SUCCESS	The event structure was created.
EFI_INVALID_PARAMETER	One of the parameters has an invalid value.
EFI_INVALID_PARAMETER	*Event* is NULL.
EFI_INVALID_PARAMETER	*Type* has an unsupported bit set.
EFI_INVALID_PARAMETER	*Type* has both EVT_NOTIFY_SIGNAL and EVT_NOTIFY_WAIT set.
EFI_INVALID_PARAMETER	*Type* has either EVT_NOTIFY_SIGNAL or EVT_NOTIFY_WAIT set and *NotifyFunction* is NULL.
EFI_INVALID_PARAMETER	*Type* has either EVT_NOTIFY_SIGNAL or EVT_NOTIFY_WAIT set and *NotifyTpl* is not a supported TPL level.
EFI_OUT_OF_RESOURCES	The event could not be allocated.

7.1.3 EFI_BOOT_SERVICES.CloseEvent()

Summary

Closes an event.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_CLOSE_EVENT) (
  IN EFI_EVENT      Event
);
```

Parameters

Event

The event to close. Type EFI_EVENT is defined in the *CreateEvent()* function description.

Description

The CloseEvent() function removes the caller's reference to the event, removes it from any event group to which it belongs, and closes it. Once the event is closed, the event is no longer valid and may not be used on any subsequent function calls. If *Event* was registered with RegisterProtocolNotify() then CloseEvent() will remove the corresponding registration. It is safe to call *CloseEvent()* within the corresponding notify function.

Status Codes Returned

EFI_SUCCESS	The event has been closed.

7.1.4 EFI_BOOT_SERVICES.SignalEvent()

Summary

Signals an event.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SIGNAL_EVENT) (
  IN EFI_EVENT Event
    );
```

Parameters

Event
The event to signal. Type EFI_EVENT is defined in the *EFI_BOOT_SERVICES.CheckEvent()* function description.

Description

The supplied *Event* is placed in the signaled state. If *Event* is already in the signaled state, then EFI_SUCCESS is returned. If *Event* is of type EVT_NOTIFY_SIGNAL, then the event's notification function is scheduled to be invoked at the event's notification task priority level. SignalEvent() may be invoked from any task priority level.

If the supplied *Event* is a part of an event group, then all of the events in the event group are also signaled and their notification functions are scheduled.

When signaling an event group, it is possible to create an event in the group, signal it and then close the event to remove it from the group. For example:

```
EFI_EVENT Event;
EFI_GUID gMyEventGroupGuid = EFI_MY_EVENT_GROUP_GUID;
gBS->CreateEventEx (
   0,
   0,
   NULL,
   NULL,
   &gMyEventGroupGuid,
   &Event
   );

gBS->SignalEvent (Event);
gBS->CloseEvent (Event);
```

Status Codes Returned

EFI_SUCCESS	The event was signaled.

7.1.5 EFI_BOOT_SERVICES.WaitForEvent()

Summary

Stops execution until an event is signaled.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_WAIT_FOR_EVENT) (
   IN UINTN             NumberOfEvents,
   IN EFI_EVENT         *Event,
   OUT UINTN            *Index
  );
```

Parameters

NumberOfEvents

The number of events in the *Event* array.

Event

An array of EFI_EVENT. Type EFI_EVENT is defined in UEFI Forum, Inc. March 2021 148 *EFI_BOOT_SERVICES.CreateEvent()* function description.

Index

Pointer to the index of the event which satisfied the wait condition.

Description

This function must be called at priority level TPL_APPLICATION. If an attempt is made to call it at any other priority level, EFI_UNSUPPORTED is returned.

The list of events in the *Event* array are evaluated in order from first to last, and this evaluation is repeated until an event is signaled or an error is detected. The following checks are performed on each event in the *Event* array.

- If an event is of type EVT_NOTIFY_SIGNAL, then EFI_INVALID_PARAMETER is returned and *Index* indicates the event that caused the failure.
- If an event is in the signaled state, the signaled state is cleared and *EFI_SUCCESS* is returned, and *Index* indicates the event that was signaled.
- If an event is not in the signaled state but does have a notification function, the notification function is queued at the event's notification task priority level. If the execution of the event's notification function causes the event to be signaled, then the signaled state is cleared, EFI_SUCCESS is returned, and *Index* indicates the event that was signaled.

To wait for a specified time, a timer event must be included in the *Event* array.

To check if an event is signaled without waiting, an already signaled event can be used as the last event in the list being checked, or the CheckEvent() interface may be used.

Status Codes Returned

EFI_SUCCESS	The event indicated by *Index* was signaled.
EFI_INVALID_PARAMETER	*NumberOfEvents* is 0.
EFI_INVALID_PARAMETER	The event indicated by *Index* is of type EVT_NOTIFY_SIGNAL.
EFI_UNSUPPORTED	The current TPL is not TPL_APPLICATION.

7.1.6 EFI_BOOT_SERVICES.CheckEvent()

Summary

Checks whether an event is in the signaled state.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_CHECK_EVENT) (
  IN EFI_EVENT                Event
);
```

Parameters

Event
The event to check. Type EFI_EVENT is defined in the CreateEvent() function description.

Description

The CheckEvent() function checks to see whether *Event* is in the signaled state. If *Event* is of type EVT_NOTIFY_SIGNAL, then EFI_INVALID_PARAMETER is returned. Otherwise, there are three possibilities:

- If *Event* is in the signaled state, it is cleared and EFI_SUCCESS is returned.
- If *Event* is not in the signaled state and has no notification function, EFI_NOT_READY is returned.
- If *Event* is not in the signaled state but does have a notification function, the notification function is queued at the event's notification task priority level. If the execution of the notification function causes *Event* to be signaled, then the signaled state is cleared and EFI_SUCCESS is returned; if the *Event* is not signaled, then EFI_NOT_READY is returned.

Status Codes Returned

EFI_SUCCESS	The event is in the signaled state.
EFI_NOT_READY	The event is not in the signaled state.
EFI_INVALID_PARAMETER	*Event* is of type EVT_NOTIFY_SIGNAL.

7.1.7 EFI_BOOT_SERVICES.SetTimer()

Summary

Sets the type of timer and the trigger time for a timer event.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SET_TIMER) (
   IN EFI_EVENT               Event,
   IN EFI_TIMER_DELAY         Type,
   IN UINT64                  TriggerTime
   );
```

Parameters

Event

The timer event that is to be signaled at the specified time. Type EFI_EVENT is defined in the CreateEvent() function description.

Type

The type of time that is specified in *TriggerTime*. See the timer delay types in “Related Definitions.”

TriggerTime

The number of 100ns units until the timer expires. A *TriggerTime* of 0 is legal. If *Type* is *TimerRelative* and *TriggerTime* is 0, then the timer event will be signaled on the next timer tick. If *Type* is TimerPeriodic and *TriggerTime* is 0, then the timer event will be signaled on every timer tick.

Related Definitions

```
//******************************************************
//EFI_TIMER_DELAY
//******************************************************
typedef enum {
   TimerCancel,
   TimerPeriodic,
   TimerRelative
} EFI_TIMER_DELAY;
```

TimerCancel

The event’s timer setting is to be cancelled and no timer trigger is to be set. *TriggerTime* is ignored when canceling a timer.

TimerPeriodic

The event is to be signaled periodically at *TriggerTime* intervals from the current time. This is the only timer trigger *Type* for which the event timer does not need to be reset for each notification. All other timer trigger types are “one shot.”

TimerRelative

The event is to be signaled in *TriggerTime* 100ns units.

Description

The SetTimer() function cancels any previous time trigger setting for the event, and sets the new trigger time for the event. This function can only be used on events of type EVT_TIMER.

Status Codes Returned

EFI_SUCCESS	The event has been set to be signaled at the requested time.
EFI_INVALID_PARAMETER	*Event* or *Type* is not valid.

7.1.8 EFI_BOOT_SERVICES.RaiseTPL()

Summary

Raises a task’s priority level and returns its previous level.

Prototype

```
typedef
EFI_TPL
(EFIAPI   *EFI_RAISE_TPL) (
```

(continues on next page)

(continued from previous page)

```
  IN EFI_TPL   NewTpl
  );
```

Parameters

NewTpl

The new task priority level. It must be greater than or equal to the current task priority level. See "Related Definitions."

Related Definitions

```
//*******************************************************
// EFI_TPL
//*******************************************************
typedef UINTN EFI_TPL

//*******************************************************
// Task Priority Levels
//*******************************************************
#define TPL_APPLICATION    4
#define TPL_CALLBACK       8
#define TPL_NOTIFY         16
#define TPL_HIGH_LEVEL     31
```

Description

This function raises the priority of the currently executing task and returns its previous priority level.

Only three task priority levels are exposed outside of the firmware during boot services execution. The first is TPL_APPLICATION where all normal execution occurs. That level may be interrupted to perform various asynchronous interrupt style notifications, which occur at the TPL_CALLBACK or TPL_NOTIFY level. By raising the task priority level to TPL_NOTIFY such notifications are masked until the task priority level is restored, thereby synchronizing execution with such notifications. Synchronous blocking I/O functions execute at TPL_NOTIFY . TPL_CALLBACK is the typically used for application level notification functions. Device drivers will typically use TPL_CALLBACK or TPL_NOTIFY for their notification functions. Applications and drivers may also use TPL_NOTIFY to protect data structures in critical sections of code.

The caller must restore the task priority level with *EFI_BOOT_SERVICES.RestoreTPL()* to the previous level before returning.

NOTE: *If* NewTpl *is below the current TPL level, then the system behavior is indeterminate. Additionally, only TPL_APPLICATION, TPL_CALLBACK, `TPL_NOTIFY <Services%20Boot%20Services.htm#TPL_NOTIFY>`__, and TPL_HIGH_LEVEL may be used. All other values are reserved for use by the firmware; using them will result in unpredictable behavior. Good coding practice dictates that all code should execute at its lowest possible TPL level, and the use of TPL levels above TPL_APPLICATION must be minimized. Executing at TPL levels above TPL_APPLICATION for extended periods of time may also result in unpredictable behavior.*

Status Codes Returned

Unlike other UEFI interface functions, *EFI_BOOT_SERVICES.RaiseTPL()* does not return a status code. Instead, it returns the previous task priority level, which is to be restored later with a matching call to RestoreTPL().

7.1.9 EFI_BOOT_SERVICES.RestoreTPL()

Summary

Restores a task's priority level to its previous value.

Prototype

```
typedef
VOID
(EFIAPI *EFI_RESTORE_TPL) (
   IN EFI_TPL OldTpl
   )
```

Parameters

OldTpl

The previous task priority level to restore (the value from a previous, matching call to *EFI_BOOT_SERVICES.RaiseTPL()* . Type *EFI_TPL* is defined in the *RaiseTPL()* function description.

Description

The *RestoreTPL()* function restores a task's priority level to its previous value. Calls to RestoreTPL() are matched with calls to RaiseTPL().

NOTE: *If* OldTpl *is above the current TPL level, then the system behavior is indeterminate. Additionally, only* TPL_APPLICATION, TPL_CALLBACK, TPL_NOTIFY, and TPL_HIGH_LEVEL*may be used*. *All other values are reserved for use by the firmware; using them will result in unpredictable behavior. Good coding practice dictates that all code should execute at its lowest possible TPL level, and the use of TPL levels above* TPL_APPLICATION *must be minimized. Executing at TPL levels above TPL_APPLICATION for extended periods of time may also result in unpredictable behavior.*

Status Codes Returned

None.

7.2 Memory Allocation Services

The functions that make up Memory Allocation Services are used during preboot to allocate and free memory, and to obtain the system's memory map, below, *Memory Allocation Functions* .

Table 7.8: Memory Allocation Functions

Name	Type	Description
AllocatePages	Boot	Allocates pages of a particular type.
FreePages	Boot	Frees allocated pages.
GetMemoryMap	Boot	Returns the current boot services memory map and memory map key.
AllocatePool	Boot	Allocates a pool of a particular type
FreePool	Boot	Frees allocated pool.

The way in which these functions are used is directly related to an important feature of UEFI memory design. This feature, which stipulates that EFI firmware owns the system's memory map during preboot, has three major consequences:

- During preboot, all components (including executing EFI images) must cooperate with the firmware by allocating and freeing memory from the system with the functions *EFI_BOOT_SERVICES.AllocatePages()* , *EFI_BOOT_SERVICES.AllocatePool()* , *EFI_BOOT_SERVICES.FreePages()* , and

EFI_BOOT_SERVICES.FreePool() . The firmware dynamically maintains the memory map as these functions are called.

- During preboot, an executing EFI Image must only use the memory it has allocated.
- Before an executing EFI image exits and returns control to the firmware, it must free all resources it has explicitly allocated. This includes all memory pages, pool allocations, open file handles, etc. Memory allocated by the firmware to load an image is freed by the firmware when the image is unloaded.

This specification describes numerous memory buffers that are allocated by a service, where it is the caller's responsibility to free the allocated memory. Unless stated otherwise in this specification, it is assumed that such memory buffers are allocated with AllocatePool() and freed with FreePool().

When memory is allocated, it is "typed" according to the values in *EFI_MEMORY_TYPE* (see the description for *EFI_BOOT_SERVICES.AllocatePages()* . Some of the types have a different usage *before* *EFI_BOOT_SERVICES.ExitBootServices()* is called than they do *afterwards*. See Table, below, *Memory Type Usage before ExitBootServices()* lists each type and its usage before the call; See Table *Memory Type Usage after ExitBootServices()* lists each type and its usage after the call. The system firmware must follow the processor-specific rules outlined in IA-32 Platforms and x64 Platforms in the layout of the EFI memory map to enable the OS to make the required virtual mappings.

Table 7.9: Memory Type Usage before ExitBootServices()

Mnemonic	**Description**
EfiReservedMemoryType	Not usable.
EfiLoaderCode	The code portions of a loaded UEFI application.
EfiLoaderData	The data portions of a loaded UEFI application and the default data allocation type used by a UEFI application to allocate pool memory.
EfiBootServicesCode	The code portions of a loaded UEFI Boot Service Driver.
EfiBootServicesData	The data portions of a loaded UEFI Boot Serve Driver, and the default data allocation type used by a UEFI Boot Service Driver to allocate pool memory.
EfiRuntimeServicesCode	The code portions of a loaded UEFI Runtime Driver.
EfiRuntimeServicesData	The data portions of a loaded UEFI Runtime Driver and the default data allocation type used by a UEFI Runtime Driver to allocate pool memory.
EfiConventionalMemory	Free (unallocated) memory.
EfiUnusableMemory	Memory in which errors have been detected.
EfiACPIReclaimMemory	Memory that holds the ACPI tables.
EfiACPIMemoryNVS	Address space reserved for use by the firmware.
EfiMemoryMappedIO	Used by system firmware to request that a memory-mapped IO region be mapped by the OS to a virtual address so it can be accessed by EFI runtime services.
EfiMemoryMappedIOPortSpace	System memory-mapped IO region that is used to translate memory cycles to IO cycles by the processor.
EfiPalCode	Address space reserved by the firmware for code that is part of the processor.
EfiPersistentMemory	A memory region that operates as EfiConventionalMemory. However, it happens to also support byte-addressable non-volatility.
EfiUnacceptedMemoryType	A memory region that represents unaccepted memory, that must be accepted by the boot target before it can be used. Unless otherwise noted, ll other EFI memory types are accepted. For platforms that support unaccepted memory, all unaccepted valid memory will be reported as unaccepted in the memory map. Unreported physical address ranges must be treated as not-present memory.

Note: *There is only one region of type* EfiMemoryMappedIoPortSpace *defined in the architecture for Itanium-based platforms. As a result, there should be one and only one region of type* EfiMemoryMappedIoPortSpace *in the EFI memory map of an Itanium-based platform.*

Table 7.10: Memory Type Usage after ExitBootServices()

Mnemonic	**Description**
EfiReservedMemoryType	Not usable.
EfiLoaderCode	The UEFI OS Loader and/or OS may use this memory as they see fit. Note: the UEFI OS loader that called *EFI_BOOT_SERVICES.ExitBootServices()* is utilizing one or more EfiLoaderCode ranges.
EfiLoaderData	The Loader and/or OS may use this memory as they see fit. Note: the OS loader that called ExitBootServices() is utilizing one or more EfiLoaderData ranges.
EfiBootServicesCode	Memory available for general use.
EfiBootServicesData	Memory available for general use.
EfiRuntimeServicesCode	The memory in this range is to be preserved by the UEFI OS loader and OS in the working and ACPI S1-S3 states.
EfiRuntimeServicesData	The memory in this range is to be preserved by the UEFI OS l loader and OS in the working and ACPI S1-S3 states.
EfiConventionalMemory	Memory available for general use.
EfiUnusableMemory	Memory that contains errors and is not to be used.
EfiACPIReclaimMemory	This memory is to be preserved by the UEFI OS loader and OS until ACPI is enabled. Once ACPI is enabled, the memory in this range is available for general use.
EfiACPIMemoryNVS	This memory is to be preserved by the UEFI OS loader and OS in the working and ACPI S1-S3 states.
EfiMemoryMappedIO	This memory is not used by the OS. All system memory-mapped IO information should come from ACPI tables.
EfiMemoryMappedIOPortSpace	This memory is not used by the OS. All system memory-mapped IO port space information should come from ACPI tables.
EfiPalCode	This memory is to be preserved by the UEFI OS loader and OS in the working and ACPI S1-S4 states. This memory may also have other attributes that are defined by the processor implementation.
EfiPersistentMemory	A memory region that operates as *EfiConventionalMemory*. However, it happens to also support byte-addressable non-volatility.
EfiUnacceptedMemoryType	A memory region that represents unaccepted memory, that must be accepted by the boot target before it can be used. Unless otherwise noted, all other EFI memory types are accepted. For platforms that support unaccepted memory, all unaccepted valid memory will be reported as unaccepted in the memory map. Unreported physical address ranges must be treated as not-present memory.

NOTE: *An image that calls* ExitBootServices() (i.e., a UEFI OS Loader) first calls *EFI_BOOT_SERVICES.GetMemoryMap() to obtain the current memory map. Following the* ExitBootServices() *call, the image implicitly owns all unused memory in the map. This includes memory types* EfiLoaderCode, EfiLoaderData, EfiBootServicesCode, EfiBootServicesData, and EfiConventionalMemory. *A UEFI OS Loader and OS must preserve the memory marked as* EfiRuntimeServicesCode *and* EfiRuntimeServicesData.

7.2.1 EFI_BOOT_SERVICES.AllocatePages()

Summary

Allocates memory pages from the system.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_ALLOCATE_PAGES) (
   IN EFI_ALLOCATE_TYPE                    Type,
   IN EFI_MEMORY_TYPE                      MemoryType,
   IN UINTN                                Pages,
   IN OUT EFI_PHYSICAL_ADDRESS             *Memory
   );
```

Parameters

Type
The type of allocation to perform. See “Related Definitions.”

MemoryType
The type of memory to allocate. The type EFI_MEMORY_TYPE is defined in “Related Definitions” below. These memory types are also described in more detail in *Memory Type Usage before ExitBootServices()*, and *Memory Type Usage after ExitBootServices()* . Normal allocations (that is, allocations by any UEFI application) are of type EfiLoaderData. *MemoryType* values in the range 0x70000000..0x7FFFFFFF are reserved for OEM use. *MemoryType* values in the range 0x80000000..0xFFFFFFFF are reserved for use by UEFI OS loaders that are provided by operating system vendors.

Pages
The number of contiguous 4 KiB pages to allocate.

Memory
Pointer to a physical address. On input, the way in which the address is used depends on the value of *Type*. See “Description” for more information. On output the address is set to the base of the page range that was allocated. See “Related Definitions.”

NOTE: UEFI Applications, UEFI Drivers, and UEFI OS Loaders *must not allocate memory of types* EfiReservedMemoryType, EfiMemoryMappedIO, *and* EfiUnacceptedMemoryType.

   EfiUnacceptedMemoryType,
   EfiMaxMemoryType
} EFI_MEMORY_TYPE;

//*******************************************************
//EFI_PHYSICAL_ADDRESS
//*******************************************************
typedef UINT64 EFI_PHYSICAL_ADDRESS;
```

Description

The AllocatePages() function allocates the requested number of pages and returns a pointer to the base address of the page range in the location referenced by *Memory*. The function scans the memory map to locate free pages. When it finds a physically contiguous block of pages that is large enough and also satisfies the allocation requirements of *Type*, it changes the memory map to indicate that the pages are now of type *MemoryType*.

In general, UEFI OS loaders and UEFI applications should allocate memory (and pool) of type EfiLoaderData. UEFI boot service drivers must allocate memory (and pool) of type EfiBootServicesData. UREFI runtime drivers should allocate memory (and pool) of type EfiRuntimeServicesData (although such allocation can only be made during boot services time).

Allocation requests of *Type* AllocateAnyPages allocate any available range of pages that satisfies the request. On input, the address pointed to by *Memory* is ignored.

Allocation requests of *Type AllocateMaxAddress* allocate any available range of pages whose uppermost address is less than or equal to the address pointed to by *Memory* on input.

Allocation requests of *Type* AllocateAddress allocate pages at the address pointed to by *Memory* on input.

NOTE: *UEFI drivers and UEFI applications that are not targeted for a specific implementation must perform memory allocations for the following runtime types using AllocateAnyPages address mode:*

```
EfiACPIReclaimMemory,
EfiACPIMemoryNVS,
EfiRuntimeServicesCode,
EfiRuntimeServicesData,
EfiReservedMemoryType.
```

Status Codes Returned

EFI_SUCCESS	The requested pages were allocated.
EFI_OUT_OF_RESOURCEST	The pages could not be allocated.
EFI_INVALID_PARAMETER	*Type* is not AllocateAnyPages or AllocateMaxAddress or AllocateAddress
EFI_INVALID_PARAMETER	*MemoryType* is in the range EfiMaxMemoryType..0x6FFFFFFF.
EFI_INVALID_PARAMETER	*MemoryType* is EfiPersistentMemoryType or EfiUnacceptedMemory.
EFI_INVALID_PARAMETER	*Memory* is NULL.
EFI_NOT_FOUND	The requested pages could not be found.

7.2.2 EFI_BOOT_SERVICES.FreePages()

Summary

Frees memory pages.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_FREE_PAGES) (
IN EFI_PHYSICAL_ADDRESS    Memory,
IN UINTN                   Pages
);
```

Parameters

Memory
The base physical address of the pages to be freed. Type *EFI_PHYSICAL_ADDRESS* is defined in the *EFI_BOOT_SERVICES.AllocatePages()* function description.

Pages
The number of contiguous 4 KiB pages to free.

Description

The FreePages() function returns memory allocated by AllocatePages() to the firmware.

Status Codes Returned

EFFI_SUCCESS	The requested memory pages were freed
EFI_NOT_FOUND	The requested memory pages were not allocated with AllocatePages().
EFI_INVALID_PARAMETER	*Memory* is not a page-aligned address or *Pages* is invalid.

7.2.3 EFI_BOOT_SERVICES.GetMemoryMap()

Summary

Returns the current memory map.

Prototype

```
typedef
EFI_STATUS
(EFIAPI \*EFI_GET_MEMORY_MAP) (
```

(continues on next page)

(continued from previous page)

```
   IN OUT UINTN                  *MemoryMapSize,
   OUT EFI_MEMORY_DESCRIPTOR     *MemoryMap,
   OUT UINTN                     *MapKey,
   OUT UINTN                     *DescriptorSize,
   OUT UINT32                    *DescriptorVersion
  );
```

Parameters

MemoryMapSize

A pointer to the size, in bytes, of the MemoryMap buffer. On input, this is the size of the buffer allocated by the caller. On output, it is the size of the buffer returned by the firmware if the buffer was large enough, or the size of the buffer needed to contain the map if the buffer was too small.

MemoryMap

A pointer to the buffer in which firmware places the current memory map. The map is an array of EFI_MEMORY_DESCRIPTORs. See "Related Definitions."

MapKey

A pointer to the location in which firmware returns the key for the current memory map.

DescriptorSize

A pointer to the location in which firmware returns the size, in bytes, of an individual EFI_MEMORY_DESCRIPTOR.

DescriptorVersion

A pointer to the location in which firmware returns the version number associated with the EFI_MEMORY_DESCRIPTOR. See "Related Definitions."

Related Definitions

..code-block:

```
//*******************************************************
//EFI_MEMORY_DESCRIPTOR
//*******************************************************
typedef struct {
   UINT32                     Type;
   EFI_PHYSICAL_ADDRESS       PhysicalStart;
   EFI_VIRTUAL_ADDRESS        VirtualStart;
   UINT64                     NumberOfPages;
   UINT64                     Attribute;
  } EFI_MEMORY_DESCRIPTOR;
```

Type

Type of the memory region. Type *EFI_MEMORY_TYPE* is defined in the *EFI_BOOT_SERVICES.AllocatePages()* function description.

PhysicalStart

Physical address of the first byte in the memory region. *PhysicalStart* must be aligned on a 4 KiB boundary, and must not be above 0xfffffffffffff000. Type *EFI_PHYSICAL_ADDRESS* is defined in the *AllocatePages()* function description.

VirtualStart

Virtual address of the first byte in the memory region. *VirtualStart* must be aligned on a 4 KiB boundary, and must not be above 0xfffffffffffff000. Type *EFI_VIRTUAL_ADDRESS* is defined in "Related Definitions."

NumberOfPages

Number of 4 KiB pages in the memory region. NumberOfPages must not be 0, and must not be any value that would represent a memory page with a start address, either physical or virtual, above 0xfffffffffffff000

Attribute

Attributes of the memory region that describe the bit mask of capabilities for that memory region, and not necessarily the current settings for that memory region. See the following "Memory Attribute Definitions."

```
//*******************************************************
// Memory Attribute Definitions
//*******************************************************
// These types can be "ORed" together as needed.
#define EFI_MEMORY_UC 0x0000000000000001
#define EFI_MEMORY_WC 0x0000000000000002
#define EFI_MEMORY_WT 0x0000000000000004
#define EFI_MEMORY_WB 0x0000000000000008
#define EFI_MEMORY_UCE 0x0000000000000010
#define EFI_MEMORY_WP 0x0000000000001000
#define EFI_MEMORY_RP 0x0000000000002000
#define EFI_MEMORY_XP 0x0000000000004000
#define EFI_MEMORY_NV 0x0000000000008000
#define EFI_MEMORY_MORE_RELIABLE 0x0000000000010000
#define EFI_MEMORY_RO 0x0000000000020000
#define EFI_MEMORY_SP 0x0000000000040000
#define EFI_MEMORY_CPU_CRYPTO 0x0000000000080000
#define EFI_MEMORY_RUNTIME 0x8000000000000000
```

EFI_MEMORY_UC

Memory cacheability attribute: The memory region supports being configured as not cacheable.

EFI_MEMORY_WC

Memory cacheability attribute: The memory region supports being configured as write combining.

EFI_MEMORY_WT

Memory cacheability attribute: The memory region supports being configured as cacheable with a "write through" policy. Writes that hit in the cache will also be written to main memory.

EFI_MEMORY_WB

Memory cacheability attribute: The memory region supports being configured as cacheable with a "write back" policy. Reads and writes that hit in the cache do not propagate to main memory. Dirty data is written back to main memory when a new cache line is allocated.

EFI_MEMORY_UCE

Memory cacheability attribute: The memory region supports being configured as not cacheable, exported, and supports the "fetch and add" semaphore mechanism.

EFI_MEMORY_WP

Physical memory protection attribute: The memory region supports being configured as write-protected by system hardware. This is typically used as a cacheability attribute today. The memory region supports being configured as cacheable with a "write protected" policy. Reads come from cache lines when possible, and read misses cause cache fills. Writes are propagated to the system bus and cause corresponding cache lines on all processors on the bus to be invalidated.

EFI_MEMORY_SP

Specific-purpose memory (SPM). The memory is earmarked for specific purposes such as for specific device drivers or applications. The SPM attribute serves as a hint to the OS to avoid allocating this memory for core OS data or code that can not be relocated. Prolonged use of this memory for purposes other than the intended purpose may result in suboptimal platform performance.

EFI_MEMORY_CPU_CRYPTO

If this flag is set, the memory region is capable of being protected with the CPU's memory cryptographic capabilities. If this flag is clear, the memory region is not capable of being protected with the CPU's memory cryptographic capabilities or the CPU does not support CPU memory cryptographic capabilities.

Note: *UEFI spec 2.5 and following: use* EFI_MEMORY_RO *as rite-protected physical memory protection attribute. Also*, EFI_MEMORY_WP *means cacheability attribute*.

EFI_MEMORY_RP

Physical memory protection attribute: The memory region supports being configured as read-protected by system hardware.

EFI_MEMORY_XP

Physical memory protection attribute: The memory region supports being configured so it is protected by system hardware from executing code.

EFI_MEMORY_NV

Runtime memory attribute: The memory region refers to persistent memory

EFI_MEMORY_MORE_RELIABLE

The memory region provides higher reliability relative to other memory in the system. If all memory has the same reliability, then this bit is not used.

EFI_MEMORY_RO

Physical memory protection attribute: The memory region supports making this memory range read-only by system hardware.

EFI_MEMORY_RUNTIME

Runtime memory attribute: The memory region needs to be given a virtual mapping by the operating system when *SetVirtualAddressMap()* is called (described in *Virtual Memory Services* .

```
//******************************************************
//EFI_VIRTUAL_ADDRESS
//******************************************************
typedef UINT64 EFI_VIRTUAL_ADDRESS;

//******************************************************
// Memory Descriptor Version Number
//******************************************************
#define EFI_MEMORY_DESCRIPTOR_VERSION 1
```

Description

The GetMemoryMap() function returns a copy of the current memory map. The map is an array of memory descriptors, each of which describes a contiguous block of memory. The map describes all of memory, no matter how it is being used. That is, it includes blocks allocated by *EFI_BOOT_SERVICES.AllocatePages()* and *EFI_BOOT_SERVICES.AllocatePool()*, as well as blocks that the firmware is using for its own purposes. The memory map is only used to describe memory that is present in the system. The firmware does not return a range description for address space regions that are not backed by physical hardware. Regions that are backed by physical hardware, but are not supposed to be accessed by the OS, must be returned as EfiReservedMemoryType. The OS may use addresses of memory ranges that are not described in the memory map at its own discretion.

Until *EFI_BOOT_SERVICES.ExitBootServices()* is called, the memory map is owned by the firmware and the currently executing UEFI Image should only use memory pages it has explicitly allocated.

If the MemoryMap buffer is too small, the EFI_BUFFER_TOO_SMALL error code is returned and the MemoryMapSize value contains the size of the buffer needed to contain the current memory map. The actual size of the buffer allocated for the consequent call to GetMemoryMap() should be bigger then the value returned in MemoryMapSize, since allocation of the new buffer may potentially increase memory map size.

On success a MapKey is returned that identifies the current memory map. The firmware's key is changed every time something in the memory map changes. In order to successfully invoke *EFI_BOOT_SERVICES.ExitBootServices()* the caller must provide the current memory map key.

The GetMemoryMap() function also returns the size and revision number of the EFI_MEMORY_DESCRIPTOR. The DescriptorSize represents the size in bytes of an EFI_MEMORY_DESCRIPTOR array element returned in MemoryMap. The size is returned to allow for future expansion of the EFI_MEMORY_DESCRIPTOR in response to hardware innovation. The structure of the EFI_MEMORY_DESCRIPTOR may be extended in the future but it will remain backwards compatible with the current definition. Thus OS software must use the DescriptorSize to find the start of each EFI_MEMORY_DESCRIPTOR in the MemoryMap array.

Status Codes Returned

EFI_SUCCESS	The memory map was returned in the *MemoryMap* buffer.
EFI_BUFFER_TOO_SMALL	The *MemoryMap* buffer was too small. Thecurrent buffer size needed to hold the memory map is returned in *MemoryMapSize*.
EFI_INVALID_PARAMETER	*MemoryMapSize* is NULL.
EFI_INVALID_PARAMETER	The *MemoryMap* buffer is not too small and *MemoryMap* is NULL.

7.2.4 EFI_BOOT_SERVICES.AllocatePool()

Summary

Allocates pool memory.

Prototype

```
typedef
EFI_STATUS
(EFIAPI  *EFI_ALLOCATE_POOL) (
   IN EFI_MEMORY_TYPE            PoolType,
   IN UINTN                      Size,
   OUT VOID                      **Buffer
   );
```

Parameters

PoolType

The type of pool to allocate. Type EFI_MEMORY_TYPE is defined in the *EFI_BOOT_SERVICES.AllocatePages()* function description. *PoolType* values in the range 0x70000000..0x7FFFFFFF are reserved for OEM use. *PoolType* values in the range 0x80000000..0xFFFFFFFF are reserved for use by UEFI OS loaders that are provided by operating system vendors.

Size

The number of bytes to allocate from the pool.

Buffer

A pointer to a pointer to the allocated buffer if the call succeeds; undefined otherwise.

Note: *UEFI applications and UEFI drivers must not allocate memory of type* EfiReservedMemoryType.

Description

The AllocatePool() function allocates a memory region of Size bytes from memory of type *PoolType* and returns the address of the allocated memory in the location referenced by *Buffer*. This function allocates pages from EfiConventionalMemory as needed to grow the requested pool type. All allocations are eight-byte aligned.

The allocated pool memory is returned to the available pool with the *EFI_BOOT_SERVICES.FreePool()* function.

Status Codes Returned

EFI_SUCCESS	The requested number of bytes was allocated.
EFI_OUT_OF_RESOURCES	The pool requested could not be allocated.
EFI_INVALID_PARAMETER	*PoolType* is in the range EfiMaxMemoryType..0x6FFFFFFF.
EFI_INVALID_PARAMETER	*PoolType* is EfiPersistentMemory.
EFI_INVALID_PARAMETER	*Buffer* is NULL.

7.2.5 EFI_BOOT_SERVICES.FreePool()

Summary

Returns pool memory to the system.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_FREE_POOL) (
   IN VOID           *Buffer
   );
```

Parameters

Buffer
Pointer to the buffer to free.

Description

The FreePool() function returns the memory specified by *Buffer* to the system. On return, the memory's type is EfiConventionalMemory. The *Buffer* that is freed must have been allocated by AllocatePool().

Status Codes Returned

EFI_SUCCESS	The memory was returned to the system.
EFI_INVALID_PARAMETER	*Buffer* was invalid.

7.3 Protocol Handler Services

In the abstract, a protocol consists of a 128-bit globally unique identifier (GUID) and a Protocol Interface structure. The structure contains the functions and instance data that are used to access a device. The functions that make up Protocol Handler Services allow applications to install a protocol on a handle, identify the handles that support a given protocol, determine whether a handle supports a given protocol, and so forth. See the Table, below.

Table 7.14: Protocol Interface Functions

Name	Type	Description
InstallProtocolInterface	Boot	Installs a protocol interface on a device handle.
UninstallProtocolInterface	Boot	Removes a protocol interface from a device handle.
ReinstallProtocolInterface	Boot	Reinstalls a protocolinterface on a device handle.

continues on next page

Table 7.14 – continued from previous page

RegisterProtocolNotify	Boot	Registers an event that is to be signaled whenever an interface is installed for a specified protocol.
LocateHandle	Boot	Returns an array of handles that support a specified protocol.
HandleProtocol	Boot	Queries a handle to determine if it supports a specified protocol.
LocateDevicePath	Boot	Locates all devices on a device path that support a specified protocol and returns the handle to the device that is closest to the path.
OpenProtocol	Boot	Adds elements to the list of agents consuming a protocol interface.
CloseProtocol	Boot	Removes elements from the list of agents consuming a protocol interface.
OpenProtocolInformation	Boot	Retrieve the list of agents that are currently consuming a protocol interface.
ConnectController	Boot	Uses a set of precedence rules to find the best set of drivers to manage a controller.
DisconnectController	Boot	Informs a set of drivers to stop managing a controller.
ProtocolsPerHandle	Boot	Retrieves the list of protocols installed on a handle. The return buffer is automatically allocated.
LocateHandleBuffer	Boot	Retrieves the list of handles from the handle database that meet the search criteria. The return buffer is automatically allocated.
LocateProtocol	Boot	Finds the first handle in the handle database the supports the requested protocol.
InstallMultipleProtocolInterfaces	Boot	Installs one or more protocol interfaces onto a handle.
UninstallMultipleProtocolInterfaces	Boot	Uninstalls one or more protocol interfaces from a handle.

The Protocol Handler boot services have been modified to take advantage of the information that is now being tracked with the *EFI_BOOT_SERVICES.OpenProtocol()* and *EFI_BOOT_SERVICES.CloseProtocol()* . Since the usage of protocol interfaces is being tracked with these new boot services, it is now possible to safely uninstall and reinstall protocol interfaces that are being consumed by UEFI drivers.

As depicted in Figure 7-1 (below) the firmware is responsible for maintaining a “data base” that shows which protocols are attached to each device handle. (The figure depicts the “data base” as a linked list, but the choice of data structure is implementation-dependent.) The “data base” is built dynamically by calling the *EFI_BOOT_SERVICES.InstallProtocolInterface()* function. Protocols can only be installed by UEFI drivers or the firmware itself. In the figure, a device handle (EFI_HANDLE) refers to a list of one or more registered protocol interfaces for that handle. The first handle in the system has four attached protocols, and the second handle has two attached protocols. Each attached protocol is represented as a GUID/Interface pointer pair. The GUID is the name of the protocol, and Interface points to a protocol instance. This data structure will typically contain a list of interface functions, and some amount of instance data.

Access to devices is initiated by calling the *EFI_BOOT_SERVICES.HandleProtocol()* function, which determines whether a handle supports a given protocol. If it does, a pointer to the matching Protocol Interface structure is returned.

When a protocol is added to the system, it may either be added to an existing device handle or it may be added to create a new device handle. See Figure 7-1 (below) shows that protocol handlers are listed for each device handle and that each protocol handler is logically a UEFI driver.

The ability to add new protocol interfaces as new handles or to layer them on existing interfaces provides great flexibility. Layering makes it possible to add a new protocol that builds on a device’s basic protocols. An example of this might be to layer on a *EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL* support that would build on the handle’s underlyin *EFI_SERIAL_IO_PROTOCOL* .

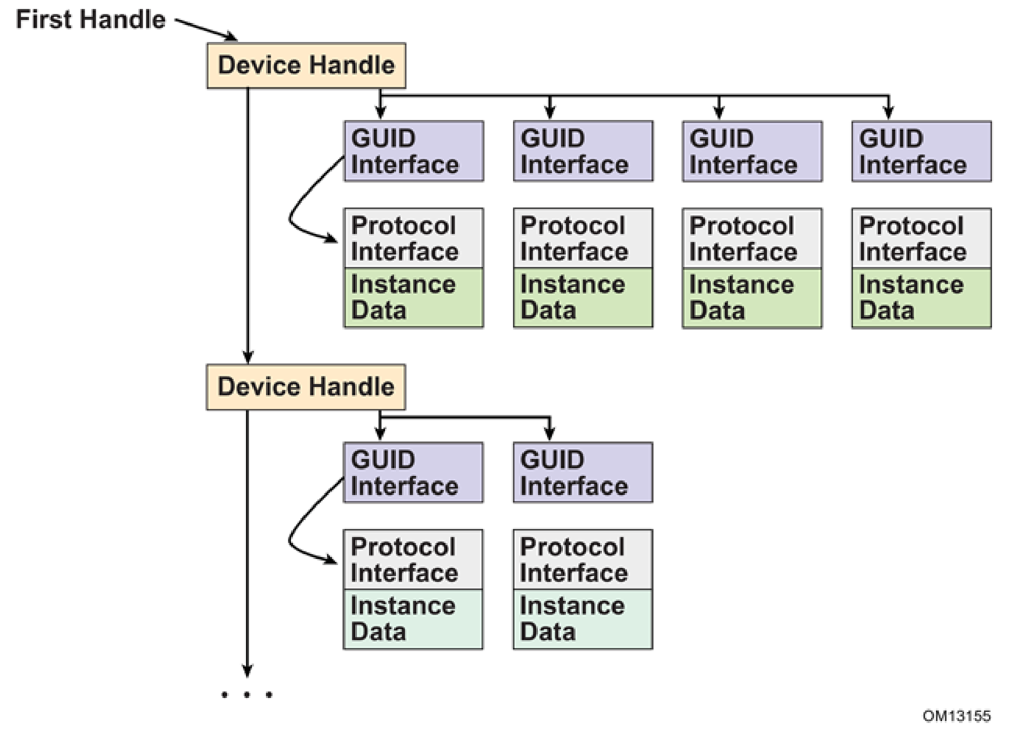

Fig. 7.1: Device Handle to Protocol Handler Mapping

The ability to add new handles can be used to generate new devices as they are found, or even to generate abstract devices. An example of this might be to add a multiplexing device that replaces ConsoleOut with a virtual device that multiplexes the *EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL* protocol onto multiple underlying device handles.

7.3.1 Driver Model Boot Services

Following is a detailed description of the new UEFI boot services that are required by the UEFI *Driver Model*. These boot services are being added to reduce the size and complexity of the bus drivers and device drivers. This, in turn, will reduce the amount of ROM space required by drivers that are programmed into ROMs on adapters or into system FLASH, and reduce the development and testing time required by driver writers.

These new services fall into two categories. The first group is used to track the usage of protocol interfaces by different agents in the system. Protocol interfaces are stored in a handle database. The handle database consists of a list of handles, and on each handle there is a list of one or more protocol interfaces. The boot services *EFI_BOOT_SERVICES.InstallProtocolInterface()* , *EFI_BOOT_SERVICES.UninstallProtocolInterface()* and *EFI_BOOT_SERVICES.ReinstallProtocolInterface()* are used to add, remove, and replace protocol interfaces in the handle database. The boot service *EFI_BOOT_SERVICES.HandleProtocol()* is used to look up a protocol interface in the handle database. However, agents that call *HandleProtocol()* are not tracked, so it is not safe to call *UninstallProtocolInterface()* or *ReinstallProtocolInterface()* because an agent may be using the protocol interface that is being removed or replaced.

The solution is to track the usage of protocol interfaces in the handle database itself. To accomplish this, each protocol interface includes a list of agents that are consuming the protocol interface. Figure 7-2 (below) shows an example handle database with these new agent lists. An agent consists of an image handle, a controller handle, and some attributes. The image handle identifies the driver or application that is consuming the protocol interface. The controller handle identifies the controller that is consuming the protocol interface. Since a driver may manage more than one controller, the combination of a driver's image handle and a controller's controller handle uniquely identifies the agent that is consuming the protocol interface. The attributes show how the protocol interface is being used.

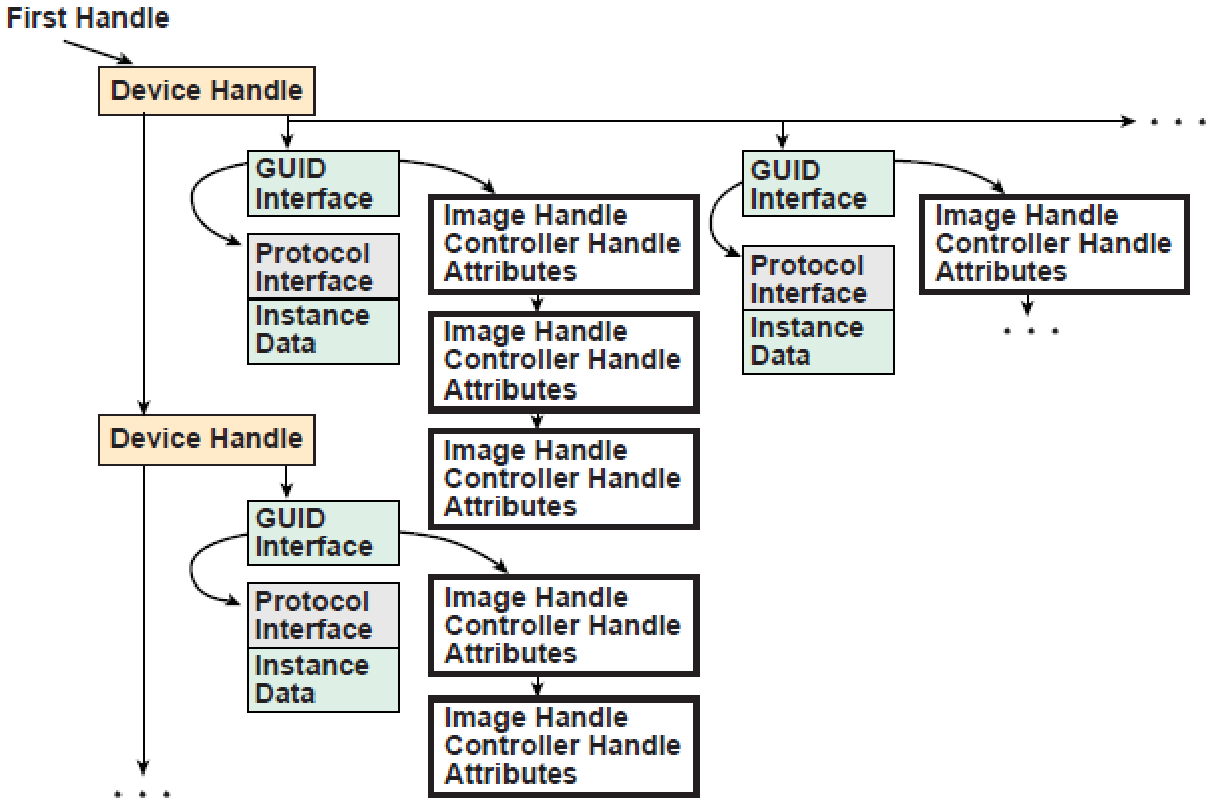

Fig. 7.2: Handle Database

In order to maintain these agent lists in the handle database, some new boot services are required. These are *EFI_BOOT_SERVICES.OpenProtocol()* , *EFI_BOOT_SERVICES.CloseProtocol()* , and *EFI_BOOT_SERVICES.OpenProtocolInformation()* . *OpenProtocol()* adds elements to the list of agents consuming a protocol interface. *CloseProtocol()* removes elements from the list of agents consuming a protocol interface, and *EFI_BOOT_SERVICES.OpenProtocolInformation()* retrieves the entire list of agents that are currently using a protocol interface.

The second group of boot services is used to deterministically connect and disconnect drivers to controllers. The boot services in this group are *EFI_BOOT_SERVICES.ConnectController()* and *EFI_BOOT_SERVICES.DisconnectController()* . These services take advantage of the new features of the handle database along with the new protocols described in this document to manage the drivers and controllers present in the system. ConnectController() uses a set of strict precedence rules to find the best set of drivers for a controller. This provides a deterministic matching of drivers to controllers with extensibility mechanisms for OEMs, IBVs, and IHVs. DisconnectController() allows drivers to be disconnected from controllers in a controlled manner, and by using the new features of the handle database it is possible to fail a disconnect request because a protocol interface cannot be released at the time of the disconnect request.

The third group of boot services is designed to help simplify the implementation of drivers, and produce drivers with smaller executable footprints. The *EFI_BOOT_SERVICES.LocateHandleBuffer()* is a new version of *EFI_BOOT_SERVICES.LocateHandle()* that allocates the required buffer for the caller. This eliminates two calls to *LocateHandle()* and a call to *EFI_BOOT_SERVICES.AllocatePool()* from the caller's code. *EFI_BOOT_SERVICES.LocateProtocol()* searches the handle database for the first protocol instance that matches the search criteria. The *EFI_BOOT_SERVICES.InstallMultipleProtocolInterfaces()* and

EFI_BOOT_SERVICES.UninstallMultipleProtocolInterfaces() are very useful to driver writers. These boot services allow one or more protocol interfaces to be added or removed from a handle. In addition, InstallMultipleProtocolInterfaces() guarantees that a duplicate device path is never added to the handle database. This is very useful to bus drivers that can create one child handle at a time, because it guarantees that the bus driver will not inadvertently create two instances of the same child handle.

7.3.2 EFI_BOOT_SERVICES.InstallProtocolInterface()

Summary

Installs a protocol interface on a device handle. If the handle does not exist, it is created and added to the list of handles in the system. InstallMultipleProtocolInterfaces() performs more error checking than InstallProtocolInterface(), so it is recommended that InstallMultipleProtocolInterfaces() be used in place of InstallProtocolInterface()

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_INSTALL_PROTOCOL_INTERFACE) (
   IN OUT EFI_HANDLE             *Handle,
   IN EFI_GUID                   *Protocol,
   IN EFI_INTERFACE_TYPE         InterfaceType,
   IN VOID                       *Interface
   );
```

Parameters

Handle

A pointer to the EFI_HANDLE on which the interface is to be installed. If * *Handle* is NULL on input, a new handle is created and returned on output. If * *Handle* is not NULL on input, the protocol is added to the handle, and the handle is returned unmodified. The type EFI_HANDLE is defined in "Related Definitions." If * *Handle* is not a valid handle, then EFI_INVALID_PARAMETER is returned.

Protocol

The numeric ID of the protocol interface. The type EFI_GUID is defined in "Related Definitions." It is the caller's responsibility to pass in a valid GUID. For a description of valid GUID values, see "Links to UEFI-Related Documents" (http://uefi.org/uefi) under the heading "RFC 4122".

InterfaceType

Indicates whether *Interface* is supplied in native form. This value indicates the original execution environment of the request. See "Related Definitions."

Interface

A pointer to the protocol interface. The Interface must adhere to the structure defined by *Protocol*. NULL can be used if a structure is not associated with *Protocol*.

Related Definitions

```
//*******************************************************
//EFI_HANDLE
//*******************************************************
typedef VOID *EFI_HANDLE;

//*******************************************************
//EFI_GUID
//*******************************************************
```

(continues on next page)

(continued from previous page)

```
typedef struct {
   UINT32      Data1;
   UINT16      Data2;
   UINT16      Data3;
   UINT8       Data4[8];
} EFI_GUID;

//*******************************************************
//EFI_INTERFACE_TYPE
//*******************************************************
typedef enum {
   EFI_NATIVE_INTERFACE
 } EFI_INTERFACE_TYPE;
```

Description

The InstallProtocolInterface() function installs a protocol interface (a GUID/Protocol Interface structure pair) on a device handle. The same GUID cannot be installed more than once onto the same handle. If installation of a duplicate GUID on a handle is attempted, an EFI_INVALID_PARAMETER will result.

Installing a protocol interface allows other components to locate the Handle, and the interfaces installed on it.

When a protocol interface is installed, the firmware calls all notification functions that have registered to wait for the installation of Protocol. For more information, see the *EFI_BOOT_SERVICES.RegisterProtocolNotify()* function description.

Status Codes Returned

EFI_SUCCESS	The protocol interface was installed.
EFI_OUT_OF_RESOURCES	Space for a new handle could not be allocated.
EFI_INVALID_PARAMETER	*HandLe* is NULL
EFI_INVALID_PARAMETER	*ProtocoL* is NULL.
EFI_INVALID_PARAMETER	*InterfaceType* is not EFI_NATIVE_INTERFACE.
EFI_INVALID_PARAMETER	*ProtocoL* is already installed on the handle specified by *HandLe*.

7.3.3 EFI_BOOT_SERVICES.UninstallProtocolInterface()

Summary

Removes a protocol interface from a device handle. It is recommended that UninstallMultipleProtocolInterfaces() be used in place of UninstallProtocolInterface().

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_UNINSTALL_PROTOCOL_INTERFACE) (
   IN EFI_HANDLE        Handle,
   IN EFI_GUID          *Protocol,
   IN VOID              *Interface
   );
```

Parameters

Handle

The handle on which the interface was installed. If Handle is not a valid handle, then EFI_INVALID_PARAMETER is returned. Type EFI_HANDLE is defined in the *EFI_BOOT_SERVICES.InstallProtocolInterface()* function description.

Protocol

The numeric ID of the interface. It is the caller's responsibility to pass in a valid GUID. For a description of valid GUID values, see "Links to UEFI-Related Documents" (http://uefi.org/uefi) under the heading "RFC 4122". Type EFI_GUID is defined in the *EFI_BOOT_SERVICES.InstallProtocolInterface()* function description.

Interface

A pointer to the interface. NULL can be used if a structure is not associated with Protocol.

Description

The UninstallProtocolInterface() function removes a protocol interface from the handle on which it was previously installed. The Protocol and Interface values define the protocol interface to remove from the handle.

The caller is responsible for ensuring that there are no references to a protocol interface that has been removed. In some cases, outstanding reference information is not available in the protocol, so the protocol, once added, cannot be removed. Examples include Console I/O, Block I/O, Disk I/O, and (in general) handles to device protocols.

If the last protocol interface is removed from a handle, the handle is freed and is no longer valid.

EFI 1.10 Extension

The extension to this service directly addresses the limitations described in the section above. There may be some drivers that are currently consuming the protocol interface that needs to be uninstalled, so it may be dangerous to just blindly remove a protocol interface from the system. Since the usage of protocol interfaces is now being tracked for components that use the *EFI_BOOT_SERVICES.OpenProtocol()* and *EFI_BOOT_SERVICES.CloseProtocol()* . boot services, a safe version of this function can be implemented. Before the protocol interface is removed, an attempt is made to force all the drivers that are consuming the protocol interface to stop consuming that protocol interface. This is done by calling the boot service *EFI_BOOT_SERVICES.DisconnectController()* . for the driver that currently have the protocol interface open with an attribute of EFI_OPEN_PROTOCOL_BY_DRIVER or EFI_OPEN_PROTOCOL_BY_DRIVER | EFI_OPEN_PROTOCOL_EXCLUSIVE.

If the disconnect succeeds, then those agents will have called the boot service *EFI_BOOT_SERVICES.CloseProtocol()* to release the protocol interface. Lastly, all of the agents that have the protocol interface open with an attribute of EFI_OPEN_PROTOCOL_BY_HANDLE_PROTOCOL, EFI_OPEN_PROTOCOL_GET_PROTOCOL, or EFI_OPEN_PROTOCOL_TEST_PROTOCOL are closed. If there are any agents remaining that still have the protocol interface open, the protocol interface is not removed from the handle and EFI_ACCESS_DENIED is returned. In addition, all of the drivers that were disconnected with the boot service DisconnectController() earlier, are reconnected with the boot service *EFI_BOOT_SERVICES.ConnectController()* . If there are no agents remaining that are consuming the protocol interface, then the protocol interface is removed from the handle as described above.

Status Codes Returned

EFI_SUCCESS	The interface was removed.
EFI_NOT_FOUND	The interface was not found.
EFI_ACCESS_DENIED	The interface was not removed because the interface is still being used by a driver.
EFI_INVALID_PARAMETER	*HandLe* is NULL.
EFI_INVALID_PARAMETER	*ProtocoL* is NULL.

7.3.4 EFI_BOOT_SERVICES.ReinstallProtocolInterface()

Summary

Reinstalls a protocol interface on a device handle.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_REINSTALL_PROTOCOL_INTERFACE) (
   IN EFI_HANDLE           Handle,
   IN EFI_GUID             *Protocol,
   IN VOID                 *OldInterface,
   IN VOID                 *NewInterface
   );
```

Parameters

Handle
Handle on which the interface is to be reinstalled. If Handle is not a valid handle, then EFI_INVALID_PARAMETER is returned. Type EFI_HANDLE is defined in the *EFI_BOOT_SERVICES.InstallProtocolInterface()* function description.

Protocol
The numeric ID of the interface. It is the caller's responsibility to pass in a valid GUID. For a description of valid GUID values, see "Links to UEFI-Related Documents" (http://uefi.org/uefi) under the heading "RFC 4122". Type EFI_GUID is defined in the InstallProtocolInterface() function description.

OldInterface
A pointer to the old interface. NULL can be used if a structure is not associated with Protocol.

NewInterface
A pointer to the new interface. NULL can be used if a structure is not associated with Protocol.

Description

The ReinstallProtocolInterface() function reinstalls a protocol interface on a device handle. The *OldInterface for Protocol* is replaced by the *NewInterface*. NewInterface may be the same as *OldInterface*. If it is, the registered protocol notifies occur for the handle without replacing the interface on the handle.

As with InstallProtocolInterface(), any process that has registered to wait for the installation of the interface is notified.

The caller is responsible for ensuring that there are no references to the *OldInterface* that is being removed.

EFI 1.10 Extension

The extension to this service directly addresses the limitations described in the section above. There may be some number of drivers currently consuming the protocol interface that is being reinstalled. In this case, it may be dangerous to replace a protocol interface in the system. It could result in an unstable state, because a driver may attempt to use the old protocol interface after a new one has been reinstalled. Since the usage of protocol interfaces is now being tracked for components that use the *EFI_BOOT_SERVICES.OpenProtocol()* and *EFI_BOOT_SERVICES.CloseProtocol()* boot services, a safe version of this function can be implemented.

When this function is called, a call is first made to the boot service UninstallProtocolInterface(). This will guarantee that all of the agents are currently consuming the protocol interface OldInterface will stop using OldInterface. If UninstallProtocolInterface() returns EFI_ACCESS_DENIED, then this function returns EFI_ACCESS_DENIED, *OldInterface* remains on Handle, and the protocol notifies are not processed because NewInterface was never installed.

If UninstallProtocolInterface() succeeds, then a call is made to the boot service *EFI_BOOT_SERVICES.InstallProtocolInterface()* to put the NewInterface onto Handle.

Finally, the boot service *EFI_BOOT_SERVICES.ConnectController()* is called so all agents that were forced to release OldInterface with UninstallProtocolInterface() can now consume the protocol interface NewInterface that was installed with InstallProtocolInterface(). After OldInterface has been replaced with NewInterface, any process that has registered to wait for the installation of the interface is notified.

Status Codes Returned

EFI_SUCCESS	The protocol interface was reinstalled.
EFI_NOT_FOUND	The OldInterface on the handle was not found.
EFI_ACCESS_DENIED	The protocol interface could not be reinstalled, because OldInterface is still being used by a driver that will not release it.
EFI_INVALID_PARAMETER	*HandLe* is NULL.
EFI_INVALID_PARAMETER	*ProtocoL* is NULL.

7.3.5 EFI_BOOT_SERVICES.RegisterProtocolNotify()

Summary

Creates an event that is to be signaled whenever an interface is installed for a specified protocol.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_REGISTER_PROTOCOL_NOTIFY) (
   IN EFI_GUID                          *Protocol,
   IN EFI_EVENT                         Event,
   OUT VOID                             **Registration
   );
```

Parameters

Protocol
The numeric ID of the protocol for which the event is to be registered. Type EFI_GUID is defined in the *EFI_BOOT_SERVICES.InstallProtocolInterface()* function description.

Event
Event that is to be signaled whenever a protocol interface is registered for Protocol. The type EFI_EVENT is defined in the CreateEvent() function description. The same EFI_EVENT may be used for multiple protocol notify registrations.

Registration
A pointer to a memory location to receive the registration value. This value must be saved and used by the notification function of Event to retrieve the list of handles that have added a protocol interface of type *Protocol.*

Description

The RegisterProtocolNotify() function creates an event that is to be signaled whenever a protocol interface is installed for Protocol by InstallProtocolInterface() or *EFI_BOOT_SERVICES.ReinstallProtocolInterface()* .

Once *Event* has been signaled, the *EFI_BOOT_SERVICES.LocateHandle()* function can be called to identify the newly installed, or reinstalled, handles that support Protocol. The *Registration* parameter in *EFI_BOOT_SERVICES.RegisterProtocolNotify()* corresponds to the *SearchKey* parameter in LocateHandle(). Note that the same handle may be returned multiple times if the handle reinstalls the target protocol ID multiple times. This is typical for removable media devices, because when such a device reappears, it will reinstall the Block I/O protocol to indicate that the device needs to be checked again. In response, layered Disk I/O and Simple File System protocols may then reinstall their protocols to indicate that they can be re-checked, and so forth.

Events that have been registered for protocol interface notification can be unregistered by calling CloseEvent().

Status Codes Returned

EFI_SUCCESS	The notification event has been registered.
EFI_OUT_OF_RESOURCES	Space for the notification event could not be allocated.
EFI_INVALID_PARAMETER	*ProtocoL* is NULL.
EFI_INVALID_PARAMETER	*Event* is NULL.
EFI_INVALID_PARAMETER	*Registration* is NULL.

7.3.6 EFI_BOOT_SERVICES.LocateHandle()

Summary

Returns an array of handles that support a specified protocol.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_LOCATE_HANDLE) (
   IN EFI_LOCATE_SEARCH_TYPE                  SearchType,
   IN EFI_GUID                                *Protocol OPTIONAL,
   IN VOID                                    *SearchKey OPTIONAL,
   IN OUT UINTN                               *BufferSize,
   OUT EFI_HANDLE                             *Buffer
   );
```

Parameters

SearchType
Specifies which handle(s) are to be returned. Type EFI_LOCATE_SEARCH_TYPE is defined in "Related Definitions."

Protocol
Specifies the protocol to search by. This parameter is only valid if SearchType is *ByProtocol*. Type EFI_GUID is defined in the *EFI_BOOT_SERVICES.InstallProtocolInterface()* function description.

SearchKey
Specifies the search key. This parameter is ignored if SearchType is *AllHandles* or *ByProtocol*. If SearchType is *ByRegisterNotify*, the parameter must be the Registration value returned by function *EFI_BOOT_SERVICES.RegisterProtocolNotify()* .

BufferSize
On input, the size in bytes of Buffer. On output, the size in bytes of the array returned in*Buffer*(if the buffer was large enough) or the size, in bytes, of the buffer needed to obtain the array (if the buffer was not large enough).

Buffer
The buffer in which the array is returned. Type EFI_HANDLE is defined in the InstallProtocolInterface() function description.

Related Definitions

```
//*******************************************************
// EFI_LOCATE_SEARCH_TYPE
//*******************************************************
typedef enum {
   AllHandles,
   ByRegisterNotify,
   ByProtocol
  } EFI_LOCATE_SEARCH_TYPE;
```

AllHandles

Protocol and SearchKey are ignored and the function returns an array of every handle in the system.

ByRegisterNotify

SearchKey supplies the Registration value returned by *EFI_BOOT_SERVICES.RegisterProtocolNotify()* . The function returns the next handle that is new for the registration. Only one handle is returned at a time, starting with the first, and the caller must loop until no more handles are returned. Protocol is ignored for this search type.

ByProtocol

All handles that support Protocol are returned. SearchKey is ignored for this search type.

Description

The LocateHandle() function returns an array of handles that match the SearchType request. If the input value of BufferSize is too small, the function returns EFI_BUFFER_TOO_SMALL and updates BufferSize to the size of the buffer needed to obtain the array.

Status Codes Returned

EFI_SUCCESS	The array of handles was returned.
EFI_NOT_FOUND	No handles match the search.
EFI_BUFFER_TOO_SMALL	The *BufferSize* is too small for the result. *BufferSize* has been updated with the size needed to complete the request.
EFI_INVALID_PARAMETER	*SearchType* is not a member of EFI_LOCATE_SEARCH_TYPE.
EFI_INVALID_PARAMETER	*SearchType* is ByRegisterNotify and *SearchKey* is NULL.
EFI_INVALID_PARAMETER	*SearchType* is ByProtocol and *ProtocoL* is NULL.
EFI_INVALID_PARAMETER	One or more matches are found and *BufferSize* is NULL.
EFI_INVALID_PARAMETER	*BufferSize* is large enough for the result and *Buffer* is NULL.

7.3.7 EFI_BOOT_SERVICES.HandleProtocol()

Summary

Queries a handle to determine if it supports a specified protocol.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_HANDLE_PROTOCOL) (
   IN EFI_HANDLE                  Handle,
   IN EFI_GUID                    *Protocol,
   OUT VOID                       **Interface
   );
```

Parameters

Handle

The handle being queried. If *Handle* is NULL, then EFI_INVALID_PARAMETER is returned. Type EFI_HANDLE is defined in the *EFI_BOOT_SERVICES.InstallProtocolInterface()* function description.

Protocol

The published unique identifier of the protocol. It is the caller's responsibility to pass in a valid GUID. For a description of valid GUID values, see "Links to UEFI-Related Documents" (http://uefi.org/uefi) under the heading "RFC 4122". Type EFI_GUID is defined in the InstallProtocolInterface() function description.

Interface

Supplies the address where a pointer to the corresponding Protocol Interface is returned. NULL will be returned in * *Interface* if a structure is not associated with *Protocol*.

Description

The HandleProtocol() function queries *Handle* to determine if it supports *Protocol*. If it does, then on return *Interface* points to a pointer to the corresponding Protocol Interface. *Interface* can then be passed to any protocol service to identify the context of the request.

EFI 1.10 Extension

The HandleProtocol() function is still available for use by old EFI applications and drivers. However, all new applications and drivers should use *EFI_BOOT_SERVICES.OpenProtocol()* in place of HandleProtocol(). The following code fragment shows a possible implementation of HandleProtocol() using OpenProtocol(). The variable EfiCoreImageHandle is the image handle of the EFI core.

```
EFI_STATUS
      HandleProtocol (
      IN EFI_HANDLE              Handle,
      IN EFI_GUID                *Protocol,
      OUT VOID                   **Interface
      )
     {
      return OpenProtocol (
         Handle,
         Protocol,
         Interface,
         EfiCoreImageHandle,
         NULL,
         EFI_OPEN_PROTOCOL_BY_HANDLE_PROTOCOL
         );
      }
```

Status Codes Returned

EFI_SUCCESS	The interface information for the specified protocol was returned.
EFI_UNSUPPORTED	The device does not support the specified protocol.
EFI_INVALID_PARAMETER	*HandLe* is NULL.
EFI_INVALID_PARAMETER	*ProtocoL* is NULL.
EFI_INVALID_PARAMETER	*Interface* is NULL.

7.3.8 EFI_BOOT_SERVICES.LocateDevicePath()

Summary

Locates the handle to a device on the device path that supports the specified protocol.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_LOCATE_DEVICE_PATH) (
   IN EFI_GUID                       *Protocol,
   IN OUT EFI_DEVICE_PATH_PROTOCOL   **DevicePath,
   OUT EFI_HANDLE                    *Device
   );
```

Parameters

Protocol
The protocol to search for. Type EFI_GUID is defined in the *EFI_BOOT_SERVICES.InstallProtocolInterface()* function description.

DevicePath
On input, a pointer to a pointer to the device path. On output, the device path pointer is modified to point to the remaining part of the device path–that is, when the function finds the closest handle, it splits the device path into two parts, stripping off the front part, and returning the remaining portion. EFI_DEVICE_PATH_PROTOCOL is defined in *EFI Device Path Protocol* .

Device
A pointer to the returned device handle. Type EFI_HANDLE is defined in the InstallProtocolInterface() function description.

Description

The LocateDevicePath() function locates all devices on *DevicePath* that support *Protocol* and returns the handle to the device that is closest to *DevicePath*. *DevicePath* is advanced over the device path nodes that were matched.

This function is useful for locating the proper instance of a protocol interface to use from a logical parent device driver. For example, a target device driver may issue the request with its own device path and locate the interfaces to perform I/O on its bus. It can also be used with a device path that contains a file path to strip off the file system portion of the device path, leaving the file path and handle to the file system driver needed to access the file.

If the handle for *DevicePath* supports the protocol (a direct match), the resulting device path is advanced to the device path terminator node. If *DevicePath* is a multi-instance device path, the function will operate on the first instance.

Status Codes Returned

EFI_SUCCESS	The resulting handle was returned.
EFI_NOT_FOUND	No handles matched the search.
EFI_INVALID_PARAMETER	*ProtocoL* is NULL
EFI_INVALID_PARAMETER	*DevicePath* is NULL.
EFI_INVALID_PARAMETER	A handle matched the search and *Device* is NULL.

7.3.9 EFI_BOOT_SERVICES.OpenProtocol()

Summary

Queries a handle to determine if it supports a specified protocol. If the protocol is supported by the handle, it opens the protocol on behalf of the calling agent. This is an extended version of the EFI boot service *EFI_BOOT_SERVICES.HandleProtocol()* .

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_OPEN_PROTOCOL) (
   IN EFI_HANDLE                       Handle,
   IN EFI_GUID                         *Protocol,
   OUT VOID                            **Interface OPTIONAL,
   IN EFI_HANDLE                       AgentHandle,
   IN EFI_HANDLE                       ControllerHandle,
   IN UINT32                           Attributes
   );
```

Parameters

Handle
The handle for the protocol interface that is being opened.

Protocol
The published unique identifier of the protocol. It is the caller's responsibility to pass in a valid GUID. For a description of valid GUID values, see "Links to UEFI-Related Documents" (http://uefi.org/uefi) under the heading "RFC 4122".

Interface
Supplies the address where a pointer to the corresponding Protocol Interface is returned. NULL will be returned in *Interface if a structure is not associated with Protocol. This parameter is optional, and will be ignored if Attributes is EFI_OPEN_PROTOCOL_TEST_PROTOCOL.

AgentHandle
The handle of the agent that is opening the protocol interface specified by *Protocol* and Interface. For agents that follow the UEFI *Driver Model*, this parameter is the handle that contains the EFI_DRIVER_BINDING_PROTOCOL instance that is produced by the UEFI driver that is opening the protocol interface. For UEFI applications, this is the image handle of the UEFI application that is opening the protocol interface. For applications that use HandleProtocol() to open a protocol interface, this parameter is the image handle of the EFI firmware.

ControllerHandle
If the agent that is opening a protocol is a driver that follows the UEFI *Driver Model*, then this parameter is the controller handle that requires the protocol interface. If the agent does not follow the UEFI *Driver Model* , then this parameter is optional and may be NULL.

Attributes
The open mode of the protocol interface specified by *Handle* and *Protocol*. See "Related Definitions" for the list of legal attributes.

Description

This function opens a protocol interface on the handle specified by *Handle* for the protocol specified by *Protocol*. The first three parameters are the same as *EFI_BOOT_SERVICES.HandleProtocol()* . The only difference is that the agent that is opening a protocol interface is tracked in an EFI's internal handle database. The tracking is used by the UEFI *Driver Model*, and also used to determine if it is safe to uninstall or reinstall a protocol interface.

The agent that is opening the protocol interface is specified by *AgentHandle*, *ControllerHandle*, and *Attributes*. If the protocol interface can be opened, then *AgentHandle*, *ControllerHandle*, and *Attributes* are added to the list of agents that are consuming the protocol interface specified by *Handl* and *Protocol*. In addition, the protocol interface is returned in *Interface*, and EFI_SUCCESS is returned. If *Attributes* is TEST_PROTOCOL, then *Interface* is optional, and can be NULL.

There are a number of reasons that this function call can return an error. If an error is returned, then *AgentHandle*, *ControllerHandle*, and *Attributes* are not added to the list of agents consuming the protocol interface specified by *Handle* and *Protocol*. *Interface* is returned unmodified for all error conditions except EFI_UNSUPPORTED and EFI_ALREADY_STARTED, NULL will be returned in * *Interface* when EFI_UNSUPPORTED and Attributes is not EFI_OPEN_PROTOCOL_TEST_PROTOCOL, the protocol interface will be returned in * *Interface* when EFI_ALREADY_STARTED.

The following is the list of conditions that must be checked before this function can return EFI_SUCCESS :

- If *Protocol* is NULL, then EFI_INVALID_PARAMETER is returned.
- If *Interface* is NULL and *Attributes* is not TEST_PROTOCOL, then EFI_INVALID_PARAMETER is returned.
- If *Handle* is NULL, then EFI_INVALID_PARAMETER is returned.
- If *Handle* does not support Protocol, then EFI_UNSUPPORTED is returned.
- If *Attributes* is not a legal value, then EFI_INVALID_PARAMETER is returned. The legal values are listed in "Related Definitions."
- If *Attributes* is BY_CHILD_CONTROLLER, BY_DRIVER, EXCLUSIVE, or BY_DRIVER|EXCULSIVE, and *AgentHandle* is NULL, then EFI_INVALID_PARAMETER is returned.
- If *Attributes* is BY_CHILD_CONTROLLER, BY_DRIVER, or BY_DRIVER|EXCULSIVE, and *ControllerHandle* is NULL, then EFI_INVALID_PARAMETER is returned.
- If *Attributes* is BY_CHILD_CONTROLLER and *Handle* is identical to *ControllerHandle*, then EFI_INVALID_PARAMETER is returned.
- If *Attributes* is BY_DRIVER, BY_DRIVER EXCLUSIVE, or EXCLUSIVE, and there are any items on the open list of the protocol interface with an attribute of EXCLUSIVE or BY_DRIVER|EXCLUSIVE, then EFI_ACCESS_DENIED is returned.
- If *Attributes* is BY_DRIVER, and there are any items on the open list of the protocol interface with an attribute of BY_DRIVER, and *AgentHandle* is the same agent handle in the open list item, then EFI_ALREADY_STARTED is returned.
- If *Attributes* is BY_DRIVER, and there are any items on the open list of the protocol interface with an attribute of BY_DRIVER, and *AgentHandle* is different than the agent handle in the open list item, then EFI_ACCESS_DENIED is returned.
- If *Attributes* is BY_DRIVER EXCLUSIVE, and there are any items on the open list of the protocol interface with an attribute of BY_DRIVER|EXCLUSIVE, and *AgentHandle* is the same agent handle in the open list item, then EFI_ALREADY_STARTED is returned.
- If *Attributes* is BY_DRIVER EXCLUSIVE, and there are any items on the open list of the protocol interface with an attribute of BY_DRIVER|EXCLUSIVE, and *AgentHandle* is different than the agent handle in the open list item, then EFI_ACCESS_DENIED is returned.
- If *Attributes* is BY_DRIVER|EXCLUSIVE or EXCLUSIVE, and there is an item on the open list of the protocol interface with an attribute of BY_DRIVER, then the boot service *EFI_BOOT_SERVICES.DisconnectController()* is called for the driver on the open list. If there is an item in the open list of the protocol interface with an attribute of BY_DRIVER remaining after the DisconnectController() call has been made, EFI_ACCESS_DENIED is returned.

Related Definitions

```
#define EFI_OPEN_PROTOCOL_BY_HANDLE_PROTOCOL   0x00000001
#define EFI_OPEN_PROTOCOL_GET_PROTOCOL         0x00000002
#define EFI_OPEN_PROTOCOL_TEST_PROTOCOL        0x00000004
#define EFI_OPEN_PROTOCOL_BY_CHILD_CONTROLLER  0x00000008
#define EFI_OPEN_PROTOCOL_BY_DRIVER            0x00000010
#define EFI_OPEN_PROTOCOL_EXCLUSIVE            0x00000020
```

The following is the list of legal values for the Attributes parameter, and how each value is used.

BY_HANDLE_PROTOCOL Used in the implementation of *EFI_BOOT_SERVICES.HandleProtocol()* . Since *EFI_BOOT_SERVICES.OpenProtocol()* performs the same function as HandleProtocol() with additional functionality, HandleProtocol() can simply call OpenProtocol() with this *Attributes* value.

GET_PROTOCOL Used by a driver to get a protocol interface from a handle. Care must be taken when using this open mode because the driver that opens a protocol interface in this manner will not be informed if the protocol interface is uninstalled or reinstalled. The caller is also not required to close the protocol interface with *EFI_BOOT_SERVICES.CloseProtocol()* .

TEST_PROTOCOL Used by a driver to test for the existence of a protocol interface on a handle. Interface is optional for this attribute value, so it is ignored, and the caller should only use the return status code. The caller is also not required to close the protocol interface with CloseProtocol().

BY_CHILD_CONTROLLER Used by bus drivers to show that a protocol interface is being used by one of the child controllers of a bus. This information is used by the boot service *EFI_BOOT_SERVICES.ConnectController()* to recursively connect all child controllers and by the boot service *EFI_BOOT_SERVICES.DisconnectController()* to get the list of child controllers that a bus driver created.

BY_DRIVER Used by a driver to gain access to a protocol interface. When this mode is used, the driver's Stop() function will be called by *EFI_BOOT_SERVICES.DisconnectController()* if the protocol interface is reinstalled or uninstalled. Once a protocol interface is opened by a driver with this attribute, no other drivers will be allowed to open the same protocol interface with the BY_DRIVER attribute.

BY_DRIVER|EXCLUSIVE Used by a driver to gain exclusive access to a protocol interface. If any other drivers have the protocol interface opened with an attribute of BY_DRIVER, then an attempt will be made to remove them with DisconnectController().

EXCLUSIVE Used by applications to gain exclusive access to a protocol interface. If any drivers have the protocol interface opened with an attribute of BY_DRIVER, then an attempt will be made to remove them by calling the driver's Stop() function.

Status Codes Returned

EFI_SUCCESS	An item was added to the open list for the protocol interface, and the protocol interface was returned in *Interface*.
EFI_INVALID_PARAMETER	*Protocol* is NULL.
EFI_INVALID_PARAMETER	*Interface* is NULL, and Attributes is not TEST_PROTOCOL.
EFI_INVALID_PARAMETER	*Handle* is NULL.
EFI_UNSUPPORTED	*Handle* does not support *Protocol*.
EFI_INVALID_PARAMETER	*Attributes* is not a legal value.
EFI_INVALID_PARAMETER	*Attributes* is BY_CHILD_CONTROLLER and *AgentHandle* is NULL.
EFI_INVALID_PARAMETER	*Attributes* is BY_DRIVER and *AgentHandle* is NULL.
EFI_INVALID_PARAMETER	*Attribute* is BY_DRIVEREXCLUSIVE and *AgentHandle* is NULL.
EFI_INVALID_PARAMETER	*Attributes* is EXCLUSIVE and *AgentHandle* is NULL.
EFI_INVALID_PARAMETER	*Attributes* is BY_CHILD_CONTROLLER and *ControllerHandle* is NULL.
EFI_INVALID_PARAMETER	*Attributes* is BY_DRIVER and *ControllerHandle* is NULL.
EFI_INVALID_PARAMETER	*Attributes* is BY_DRIVEREXCLUSIVE and *ControllerHandle* is NULL.

continues on next page

Table 7.22 – continued from previous page

EFI_INVALID_PARAMETER	*Attributes* is BY_CHILD_CONTROLLER and *Handle* is identical to *ControllerHandle*.
EFI_ACCESS_DENIED	*Attributes* is BY_DRIVER and there is an item on the open list with an attribute of BY_DRIVEREXCLUSIVE or EXCLUSIVE.
EFI_ACCESS_DENIED	*Attributes* is BY_DRIVEREXCLUSIVE and there is an item on the open list with an attribute of EXCLUSIVE.
EFI_ACCESS_DENIED	*Attributes* is EXCLUSIVE and there is an item on the open list with an attribute of BY_DRIVEREXCLUSIVE or EXCLUSIVE.
EFI_ALREADY_STARTED	*Attributes* is BY_DRIVER and there is an item on the open list with an attribute of BY_DRIVER whose agent handle is the same as *AgentHandle*.
EFI_ACCESS_DENIED	*Attributes* is BY_DRIVER and there is an item on the open list with an attribute of BY_DRIVER whose agent handle is different than *AgentHandle*.
EFI_ALREADY_STARTED	*Attributes* is BY_DRIVEREXCLUSIVE and there is an item on the open list with an attribute of BY_DRIVEREXCLUSIVE whose agent handle is the same as *AgentHandle*.
EFI_ACCESS_DENIED	*Attributes* is BY_DRIVEREXCLUSIVE and there is an item on the open list with an attribute of BY_DRIVEREXCLUSIVE whose agent handle is different than *AgentHandle*.
EFI_ACCESS_DENIED	*Attributes* is BY_DRIVEREXCLSUIVE or EXCLUSIVE and there are items in the open list with an attribute of BY_DRIVER that could not be removed when *EFI_BOOT_SERVICES.DisconnectController()* was called for that open item.

7.3.10 EFI_BOOT_SERVICES.CloseProtocol()

Summary

Closes a protocol on a handle that was opened using *EFI_BOOT_SERVICES.OpenProtocol()* .

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_CLOSE_PROTOCOL) (
   IN EFI_HANDLE                Handle,
   IN EFI_GUID                  *Protocol,
   IN EFI_HANDLE                AgentHandle,
   IN EFI_HANDLE                ControllerHandle
   );
```

Parameters

Handle

The handle for the protocol interface that was previously opened with OpenProtocol(), and is now being closed.

Protocol

The published unique identifier of the protocol. It is the caller's responsibility to pass in a valid GUID. For a description of valid GUID values, see "Links to UEFI-Related Documents" (http://uefi.org/uefi) under the heading "RFC 4122".

AgentHandle

The handle of the agent that is closing the protocol interface. For agents that follow the UEFI *Driver Model*, this parameter is the handle that contains the EFI_DRIVER_BINDING_PROTOCOL instance that is produced by the UEFI driver that is opening the protocol interface. For UEFI applications, this is the image handle of the UEFI application. For applications that used *EFI_BOOT_SERVICES.HandleProtocol()* to open the protocol interface, this will be the image handle of the EFI firmware.

ControllerHandle

If the agent that opened a protocol is a driver that follows the UEFI *Driver Model*, then this parameter is the controller handle that required the protocol interface. If the agent does not follow the UEFI *Driver Model*, then this parameter is optional and may be NULL.

Description

This function updates the handle database to show that the protocol instance specified by *Handle* and *Protocol* is no longer required by the agent and controller specified *AgentHandle* and *ControllerHandle.*

If *Handle* or *AgentHandle* is NULL, then EFI_INVALID_PARAMETER is returned. If *ControllerHandle* is not NULL, and *ControllerHandle* is NULL, then EFI_INVALID_PARAMETER is returned. If *Protocol* is NULL, then EFI_INVALID_PARAMETER is returned.

If the interface specified by *Protocol* is not supported by the handle specified by *Handle*, then EFI_NOT_FOUND is returned.

If the interface specified by *Protocol* is supported by the handle specified by *Handle*, then a check is made to see if the protocol instance specified by *Protocol* and *Handle* was opened by *AgentHandle* and *ControllerHandle* with *EFI_BOOT_SERVICES.OpenProtocol()* . If the protocol instance was not opened by *AgentHandle* and *ControllerHandle*, then EFI_NOT_FOUND is returned. If the protocol instance was opened by *AgentHandle* and *ControllerHandle*, then all of those references are removed from the handle database, and EFI_SUCCESS is returned.

Status Codes Returned

EFI_SUCCESS	The protocol instance was closed.
EFI_INVALID_PARAMETER	*Handle* is NULL.
EFI_INVALID_PARAMETER	*AgentHandle* is NULL.
EFI_INVALID_PARAMETER	*ControllerHandle* is not NULL and *ControllerHandle* is NULL.
EFI_INVALID_PARAMETER	*Protocol* is NULL.
EFI_NOT_FOUND	*Handle* does not support the protocol specified by *Protocol*.
EFI_NOT_FOUND	The protocol interface specified by *Handle* and *Protocol* is not currently open by *AgentHandle* and *ControllerHandle*.

Examples

```
EFI_BOOT_SERVICES                    *gBS;
EFI_HANDLE                           ImageHandle;
EFI_DRIVER_BINDING_PROTOCOL          *This;
IN EFI_HANDLE                        ControllerHandle,
extern EFI_GUID                      gEfiXyzIoProtocol;
EFI_STATUS                           Status;
```

(continues on next page)

(continued from previous page)

```
//
// Close the XYZ I/O Protocol that was opened on behalf of ControllerHandle
//
Status = gBS->CloseProtocol (
         ControllerHandle,
         &gEfiXyzIoProtocol,
         This->DriverBindingHandle,
         ControllerHandle
         );

//
// Close the XYZ I/O Protocol that was opened with BY_HANDLE_PROTOCOL
//
Status = gBS->CloseProtocol (
         ControllerHandle,
         &gEfiXyzIoProtocol,
         ImageHandle,
         NULL
         );
```

7.3.11 EFI_BOOT_SERVICES.OpenProtocolInformation()

Summary

Retrieves the list of agents that currently have a protocol interface opened.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_OPEN_PROTOCOL_INFORMATION) (
   IN EFI_HANDLE                           Handle,
   IN EFI_GUID                             *Protocol,
   OUT EFI_OPEN_PROTOCOL_INFORMATION_ENTRY **EntryBuffer,
   OUT UINTN                               *EntryCount
   );
```

Parameters

Handle
The handle for the protocol interface that is being queried.

Protocol
The published unique identifier of the protocol. It is the caller's responsibility to pass in a valid GUID. For a description of valid GUID values, see "Links to UEFI-Related Documents" (http://uefi.org/uefi) under the heading "RFC 4122".

EntryBuffer
A pointer to a buffer of open protocol information in the form of EFI_OPEN_PROTOCOL_INFORMATION_ENTRY structures. See "Related Definitions" for the declaration of this type. The buffer is allocated by this service, and it is the caller's responsibility to free this buffer when the caller no longer requires the buffer's contents.

EntryCount

A pointer to the number of entries in *EntryBuffer*.

Related Definitions

```
typedef struct {
   EFI_HANDLE                          AgentHandle;
   EFI_HANDLE                          ControllerHandle;
   UINT32                              Attributes;
   UINT32                              OpenCount;
  } EFI_OPEN_PROTOCOL_INFORMATION_ENTRY;
```

Description

This function allocates and returns a buffer of EFI_OPEN_PROTOCOL_INFORMATION_ENTRY structures. The buffer is returned in *EntryBuffer*, and the number of entries is returned in *EntryCount*.

If the interface specified by Protocol is not supported by the handle specified by Handle, then EFI_NOT_FOUND is returned.

If the interface specified by Protocol is supported by the handle specified by Handle, then EntryBuffer is allocated with the boot service *EFI_BOOT_SERVICES.AllocatePool()* , and EntryCount is set to the number of entries in *EntryBuffer*. Each entry of *EntryBuffer* is filled in with the image handle, controller handle, and attributes that were passed to *EFI_BOOT_SERVICES.OpenProtocol()* when the protocol interface was opened. The field *OpenCount* shows the number of times that the protocol interface has been opened by the agent specified by *ImageHandle*, *ControllerHandle*, and *Attributes*. After the contents of *EntryBuffer* have been filled in, EFI_SUCCESS is returned. It is the caller's responsibility to call *EFI_BOOT_SERVICES.FreePool()* on *EntryBuffer* when the caller no longer required the contents of *EntryBuffer*.

If there are not enough resources available to allocate *EntryBuffer*, then EFI_OUT_OF_RESOURCES is returned.

Status Codes Returned

EFI_SUCCESS	The open protocol information was returned in *EntryBuffer*, and the number of entries was returned *EntryCount*.
EFI_NOT_FOUND	*Handle* does not support the protocol specified by *Protocol*.
EFI_OUT_OF_RESOURCES	There are not enough resources available to allocate *EntryBuffer*.

Examples

See example in the *EFI_BOOT_SERVICES.LocateHandleBuffer()* function description for an example on how LocateHandleBuffer(), OpenProtocol(), and *EFI_BOOT_SERVICES.OpenProtocolInformation()* can be used to traverse the entire handle database.

7.3.12 EFI_BOOT_SERVICES.ConnectController()

Summary

Connects one or more drivers to a controller.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_CONNECT_CONTROLLER) (
   IN EFI_HANDLE                       ControllerHandle,
   IN EFI_HANDLE                       *DriverImageHandle OPTIONAL,
```

(continues on next page)

(continued from previous page)

```
  IN EFI_DEVICE_PATH_PROTOCOL         *RemainingDevicePath OPTIONAL,
  IN BOOLEAN Recursive
  );
```

Parameters

ControllerHandle
The handle of the controller to which driver(s) are to be connected.

DriverImageHandle
A pointer to an ordered list handles that support the EFI_DRIVER_BINDING_PROTOCOL. The list is terminated by a NULL handle value. These handles are candidates for the Driver Binding Protocol(s) that will manage the controller specified by *ControllerHandle*. This is an optional parameter that may be NULL. This parameter is typically used to debug new drivers.

RemainingDevicePath
A pointer to the device path that specifies a child of the controller specified by *ControllerHandle*. This is an optional parameter that may be NULL. If it is NULL, then handles for all the children of *ControllerHandle* will be created. This parameter is passed unchanged to the *EFI_DRIVER_BINDING_PROTOCOL.Supported()* and *EFI_DRIVER_BINDING_PROTOCOL.Start()* services of the EFI_DRIVER_BINDING_PROTOCOL attached to *ControllerHandle*.

Recursive
If **TRUE**, then ConnectController() is called recursively until the entire tree of controllers below the controller specified by *ControllerHandle* have been created. If **FALSE**, then the tree of controllers is only expanded one level.

Description

This function connects one or more drivers to the controller specified by *ControllerHandle*. If *ControllerHandle* is NULL, then EFI_INVALID_PARAMETER is returned. If there are no EFI_DRIVER_BINDING_PROTOCOL instances present in the system, then return EFI_NOT_FOUND. If there are not enough resources available to complete this function, then EFI_OUT_OF_RESOURCES is returned.

If the platform supports user authentication, as specified in *User Identification* the device path associated with *ControllerHandle* is checked against the connect permissions in the current user profile. If forbidden, then EFI_SECURITY_VIOLATION is returned. Then, before connecting any of the *DriverImageHandles*, the device path associated with the handle is checked against the connect permissions in the current user profile.

If *Recursive* is **FALSE**, then this function returns after all drivers have been connected to *ControllerHandle*. If *Recursive* is **TRUE**, then ConnectController() is called recursively on all of the child controllers of *ControllerHandle*. The child controllers can be identified by searching the handle database for all the controllers that have opened ControllerHandle with an attribute of EFI_OPEN_PROTOCOL_BY_CHILD_CONTROLLER.

This functions uses five precedence rules when deciding the order that drivers are tested against controllers. These five rules from highest precedence to lowest precedence are as follows:

1. *Context Override* : *DriverImageHandle* is an ordered list of handles that support the EFI_DRIVER_BINDING_PROTOCOL. The highest priority image handle is the first element of the list, and the lowest priority image handle is the last element of the list. The list is terminated with a NULL image handle.
2. *Platform Driver Override*: If an *EFI_PLATFORM_DRIVER_OVERRIDE_PROTOCOL* instance is present in the system, then the *EFI Platform Driver Override Protocol* service of this protocol is used to retrieve an ordered list of image handles for *ControllerHandle*. From this list, the image handles found in rule (1) above are removed. The first image handle returned from GetDriver() has the highest precedence, and the last image handle returned from GetDriver() has the lowest precedence. The ordered list is terminated when GetDriver() returns EFI_NOT_FOUND. It is legal for no image handles to be returned by GetDriver(). There can be at most a single

instance in the system of the EFI_PLATFORM_DRIVER_OVERRIDE_PROTOCOL. If there is more than one, then the system behavior is not deterministic.

3. *Driver Family Override Search* : The list of available driver image handles can be found by using the boot service *EFI_BOOT_SERVICES.LocateHandle()* with a *SearchType* of *ByProtocol* for the GUID of the EFI_DRIVER_FAMILY_OVERRIDE_PROTOCOL. From this list, the image handles found in rules (1), and (2) above are removed. The remaining image handles are sorted from highest to lowest based on the value returned from the GetVersion() function of the EFI_DRIVER_FAMILY_OVERRIDE_PROTOCOL associated with each image handle.
4. *Bus Specific Driver Override*: If there is an instance of the EFI_BUS_SPECIFIC_DRIVER_OVERRIDE_PROTOCOL attached to *ControllerHandle*, then the *EFI Platform Driver Override Protocol* service of this protocol is used to retrieve an ordered list of image handle for *ControllerHandle*. From this list, the image handles found in rules (1), (2), and (3) above are removed. The first image handle returned from GetDriver() has the highest precedence, and the last image handle returned from GetDriver() has the lowest precedence. The ordered list is terminated when GetDriver() returns EFI_NOT_FOUND. It is legal for no image handles to be returned by GetDriver().
5. *Driver Binding Search*: The list of available driver image handles can be found by using the boot service *EFI_BOOT_SERVICES.LocateHandle()* with a *SearchType* of *ByProtocol* for the GUID of the EFI_DRIVER_BINDING_PROTOCOL. From this list, the image handles found in rules (1), (2), (3), and (4) above are removed. The remaining image handles are sorted from highest to lowest based on the *Version* field of the EFI_DRIVER_BINDING_PROTOCOL instance associated with each image handle.

Each of the five groups of image handles listed above is tested against *ControllerHandle* in order by using the *EFI_DRIVER_BINDING_PROTOCOL.Supported()* . *RemainingDevicePath* is passed into Supported() unmodified. The first image handle whose Supported() service returns EFI_SUCCESS is marked so the image handle will not be tried again during this call to ConnectController(). Then, *EFI_DRIVER_BINDING_PROTOCOL.Start()* service of the EFI_DRIVER_BINDING_PROTOCOL is called for *ControllerHandle*. Once again, *RemainingDevicePath* is passed in unmodified. Every time Supported() returns EFI_SUCCESS, the search for drivers restarts with the highest precedence image handle. This process is repeated until no image handles pass the Supported() check.

If at least one image handle returned EFI_SUCCESS from its Start() service, then EFI_SUCCESS is returned.

If no image handles returned EFI_SUCCESS from their Start() service then EFI_NOT_FOUND is returned unless *RemainingDevicePath* is not NULL, and *RemainingDevicePath* is an **End Node**. In this special case, EFI_SUCCESS is returned because it is not an error to fail to start a child controller that is specified by an End Device Path Node.

Status Codes Returned

EFI_SUCCESS	One or more drivers were connected to ControllerHandle.
EFI_SUCCESS	No drivers were connected to ControllerHandle, but RemainingDevicePath is not NULL, and it is an End Device Path Node.
EFI_INVALID_PARAMETER	*ControllerHandle* is NULL.
EFI_NOT_FOUND	There are no EFI_DRIVER_BINDING_PROTOCOL instances present in the system.
EFI_NOT_FOUND	No drivers were connected to ControllerHandle.
EFI_SECURITY_VIOLATION	The user has no permission to start UEFI device drivers on the device path associated with the *ControllerHandle* or specified by the *RemainingDevicePath*.

Examples

```
//
// Connect All Handles Example
//   The following example recursively connects all controllers in a platform.

do {
//
// Find the handle that best matches the Device Path. If it is only a
// partial match the remaining part of the device path is returned in
// RemainingDevicePath.
//
RemainingDevicePath = DevicePath;
Status = gBS->LocateDevicePath (
         &gEfiDevicePathProtocolGuid,
```

(continues on next page)

(continued from previous page)

```
         &RemainingDevicePath,
         &Handle
         );
 if (EFI_ERROR(Status)) {
 return EFI_NOT_FOUND;
 }

 //
 // Connect all drivers that apply to Handle and RemainingDevicePath
 // If no drivers are connected Handle, then return EFI_NOT_FOUND
 // The Recursive flag is FALSE so only one level will be expanded.
 //
 Status = gBS->ConnectController (
         Handle,
         NULL,
         RemainingDevicePath,
         FALSE
         );

 if (EFI_ERROR(Status)) {
 return EFI_NOT_FOUND;
 }

 //
 // Loop until RemainingDevicePath is an empty device path
 //
} while (!IsDevicePathEnd (RemainingDevicePath));

 //
 // A handle with DevicePath exists in the handle database
 //
 return EFI_SUCCESS;
```

7.3.13 EFI_BOOT_SERVICES.DisconnectController()

Summary

Disconnects one or more drivers from a controller.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_DISCONNECT_CONTROLLER) (
   IN EFI_HANDLE                       ControllerHandle,
   IN EFI_HANDLE                       DriverImageHandle OPTIONAL,
   IN EFI_HANDLE                       ChildHandle OPTIONAL
   );
```

Parameters

ControllerHandle
The handle of the controller from which driver(s) are to be disconnected.

DriverImageHandle

The driver to disconnect from *ControllerHandle*. If *DriverImageHandle* is NULL, then all the drivers currently managing *ControllerHandle* are disconnected from *ControllerHandle*.

ChildHandle

The handle of the child to destroy. If *ChildHandle* is NULL, then all the children of *ControllerHandle* are destroyed before the drivers are disconnected from *ControllerHandle*.

Description

This function disconnects one or more drivers from the controller specified by *ControllerHandle*. If *DriverImageHandle* is NULL, then all of the drivers currently managing *ontrollerHandle* are disconnected from *ControllerHandle*. If *DriverImageHandle* is not NULL, then only the driver specified by *DriverImageHandle* is disconnected from *ControllerHandle*. If *ChildHandle* is NULL, then all of the children of *ControllerHandle* are destroyed before the drivers are disconnected from *ControllerHandle*. If *ChildHandle* is not NULL, then only the child controller specified by *ChildHandle* is destroyed. If *ChildHandle* is the only child of *ControllerHandle*, then the driver specified by *DriverImageHandle* will be disconnected from *ontrollerHandle*. A driver is disconnected from a controller by calling the Stop() service of the EFI_DRIVER_BINDING_PROTOCOL. The EFI_DRIVER_BINDING_PROTOCOL is on the driver image handle, and the handle of the controller is passed into the Stop() service. The list of drivers managing a controller, and the list of children for a specific controller can be retrieved from the handle database with the boot service *EFI_BOOT_SERVICES.OpenProtocolInformation()*. If all the required drivers are disconnected from *ControllerHandle*, then EFI_SUCCESS is returned.

If *ControllerHandle* is NULL, then EFI_INVALID_PARAMETER is returned. If no drivers are managing *ControllerHandle*, then EFI_SUCCESS is returned. If *DriverImageHandle* is not NULL, and *DriverImageHandle* is *not a valid EFI_HANDLE*, then EFI_INVALID_PARAMETER is returned. If *DriverImageHandle* is not NULL, and *DriverImageHandle* is not currently managing *ControllerHandle*, then EFI_SUCCESS is returned. If *ChildHandle* is not NULL, and *ChildHandle* is *not a valid EFI_HANDLE*, then EFI_INVALID_PARAMETER is returned. If there are not enough resources available to disconnect drivers from *ControllerHandle*, then EFI_OUT_OF_RESOURCES is returned.

Status Codes Returned

EFI_SUCCESS	One or more drivers were disconnected from the controller.
EFI_SUCCESS	On entry, no drivers are managing *ControllerHandle*.
EFI_SUCCESS	*DriverImageHandle* is not NULL, and on entry *DriverImageHandle* is not managing *ControllerHandle*.
EFI_INVALID_PARAMETER	*ControllerHandle* is NULL.
EFI_INVALID_PARAMETER	*DriverImageHandle* is not NULL, and it is not a valid EFI_HANDLE.
EFI_INVALID_PARAMETER	*ChildHandle* is not NULL, and it is not a valid EFI_HANDLE.
EFI_OUT_OF_RESOURCES	There are not enough resources available to disconnect any drivers from *ControllerHandle*.
EFI_DEVICE_ERROR	The controller could not be disconnected because of a device error.
EFI_INVALID_PARAMETER	*DriverImageHandle* does not support the EFI_DRIVER_BINDING_PROTOCOL.

Examples

```
//
// Disconnect All Handles Example
//  The following example recursively disconnects all drivers from all
//  controllers in a platform
//

EFI_STATUS                          Status;
EFI_BOOT_SERVICES                   *gBS;
```

(continues on next page)

(continued from previous page)

```
UINTN                               HandleCount;
EFI_HANDLE                          *HandleBuffer;
UINTN                               HandleIndex;

//
// Retrieve the list of all handles from the handle database
//
Status = gBS->LocateHandleBuffer (
         AllHandles,
         NULL,
         NULL,
         &HandleCount,
         &HandleBuffer
         );
if (!EFI_ERROR (Status)) {
 for (HandleIndex = 0; HandleIndex < HandleCount; HandleIndex++) {
  Status =  gBS->DisconnectController (
            HandleBuffer[HandleIndex],
            NULL,
            NULL
            );

 }
 gBS->FreePool(HandleBuffer);
```

7.3.14 EFI_BOOT_SERVICES.ProtocolsPerHandle()

Summary

Retrieves the list of protocol interface GUIDs that are installed on a handle in a buffer allocated from pool.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PROTOCOLS_PER_HANDLE) (
   IN EFI_HANDLE                             Handle,
   OUT EFI_GUID                              ***ProtocolBuffer,
   OUT UINTN                                 *ProtocolBufferCount
   );
```

Parameters

Handle

The handle from which to retrieve the list of protocol interface GUIDs.

ProtocolBuffer

A pointer to the list of protocol interface GUID pointers that are installed on *Handle*. This buffer is allocated with a call to the Boot Service *EFI_BOOT_SERVICES.AllocatePool()* . It is the caller's responsibility to call the Boot Service *EFI_BOOT_SERVICES.FreePool()* when the caller no longer requires the contents of *ProtocolBuffer*.

ProtocolBufferCount

A pointer to the number of GUID pointers present in *ProtocolBuffer*.

Description

The ProtocolsPerHandle() function retrieves the list of protocol interface GUIDs that are installed on *Handle*. The list is returned in ProtocolBuffer, and the number of GUID pointers in *ProtocolBuffer* is returned in *ProtocolBufferCount*.

If *Handle* is NULL or Handle is NULL, then EFI_INVALID_PARAMETER is returned.

If *ProtocolBuffer* is NULL, then EFI_INVALID_PAREMETER is returned.

If *ProtocolBufferCount* is NULL, then EFI_INVALID_PARAMETER is returned.

If there are not enough resources available to allocate *ProtocolBuffer*, then EFI_OUT_OF_RESOURCES is returned.

Status Codes Returned

EFI_SUCCESS	The list of protocol interface GUIDs installed on *Handle* was returned in *ProtocolBuffer*. The number of protocol interface GUIDs was returned in *ProtocolBufferCount*.
EFI_INVALID_PARAMETER	*Handle* is NULL.
EFI_INVALID_PARAMETER	*ProtocolBuffer* is NULL.
EFI_INVALID_PARAMETER	*ProtocolBufferCount* is NULL.
EFI_OUT_OF_RESOURCES	There is not enough pool memory to store the results.

Examples

See example in the *EFI_BOOT_SERVICES.LocateHandleBuffer()* function description for an example on how LocateHandleBuffer(), *EFI_BOOT_SERVICES.ProtocolsPerHandle()* , *EFI_BOOT_SERVICES.OpenProtocol()* . and *EFI_BOOT_SERVICES.OpenProtocolInformation()* can be used to traverse the entire handle database.

7.3.15 EFI_BOOT_SERVICES.LocateHandleBuffer()

Summary

Returns an array of handles that support the requested protocol in a buffer allocated from pool.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_LOCATE_HANDLE_BUFFER) (
   IN EFI_LOCATE_SEARCH_TYPE                    SearchType,
   IN EFI_GUID                                  *Protocol OPTIONAL,
   IN VOID                                      *SearchKey OPTIONAL,
   OUT UINTN                                    *NoHandles,
   OUT EFI_HANDLE                               **Buffer
   );
```

Parameters

SearchType
Specifies which handle(s) are to be returned.

Protocol
Provides the protocol to search by. This parameter is only valid for a *SearchType* of *ByProtocol*.

SearchKey
Supplies the search key depending on the *SearchType*.

NoHandles

The number of handles returned in *Buffer*.

Buffer

A pointer to the buffer to return the requested array of handles that support *Protocol*. This buffer is allocated with a call to the Boot Service *EFI_BOOT_SERVICES.AllocatePool()* . It is the caller's responsibility to call the Boot Service *EFI_BOOT_SERVICES.FreePool()* when the caller no longer requires the contents of *Buffer*.

Description

The LocateHandleBuffer() function returns one or more handles that match the *SearchType* request. *Buffer* is allocated from pool, and the number of entries in *Buffer* is returned in *NoHandles*. Each *SearchType* is described below:

AllHandles

Protocol and *SearchKey* are ignored and the function returns an array of every handle in the system.

ByRegisterNotify

SearchKey supplies the Registration returned by *EFI_BOOT_SERVICES.RegisterProtocolNotify()* . The function returns the next handle that is new for the Registration. Only one handle is returned at a time, and the caller must loop until no more handles are returned. *Protocol* is ignored for this search type.

ByProtocol

All handles that support *Protocol* are returned. *SearchKey* is ignored for this search type.

If *NoHandles* is NULL, then EFI_INVALID_PARAMETER is returned.

If *Buffer* is NULL, then EFI_INVALID_PARAMETER is returned.

If there are no handles in the handle database that match the search criteria, then EFI_NOT_FOUND is returned.

If there are not enough resources available to allocate *Buffer*, then EFI_OUT_OF_RESOURCES is returned.

Status Codes Returned

EFI_SUCCESS	The array of handles was returned in *Buffer*, and the number of handles in *Buffer* was returned in *NoHandles*.
EFI_INVALID_PARAMETER	*NoHandles* is NULL
EFI_INVALID_PARAMETER	*Buffer* is NULL
EFI_NOT_FOUND	No handles match the search.
EFI_OUT_OF_RESOURCES	There is not enough pool memory to store the matching results.

Examples

```
//
// The following example traverses the entire handle database. First all of
// the handles in the handle database are retrieved by using
// LocateHandleBuffer(). Then it uses ProtocolsPerHandle() to retrieve the
// list of protocol GUIDs attached to each handle. Then it uses OpenProtocol()
// to get the protocol instance associated with each protocol GUID on the
// handle. Finally, it uses OpenProtocolInformation() to retrieve the list of
// agents that have opened the protocol on the handle. The caller of these
// functions must make sure that they free the return buffers with FreePool()
// when they are done.
//

EFI_STATUS                                      Status;

            NULL,
            EFI_OPEN_PROTOCOL_GET_PROTOCOL
            );

   //
   // Retrieve the list of agents that have opened each protocol
   //
   Status = gBS->OpenProtocolInformation (
            HandleBuffer[HandleIndex],
            ProtocolGuidArray[ProtocolIndex],
            &OpenInfo,
```

(continues on next page)

(continued from previous page)

```
            &OpenInfoCount
            );
   if (!EFI_ERROR (Status)) {
     for (OpenInfoIndex=0;OpenInfoIndex<OpenInfoCount;OpenInfoIndex++) {
      //
      // HandleBuffer[HandleIndex] is the handle
      // ProtocolGuidArray[ProtocolIndex] is the protocol GUID
      // Instance is the protocol instance for the protocol
      // OpenInfo[OpenInfoIndex] is an agent that has opened a protocol
      //
     }
     if (OpenInfo != NULL) {
       gBS->FreePool(OpenInfo);
     }
    }
   }
   if (ProtocolGuidArray != NULL) {
    gBS->FreePool(ProtocolGuidArray);
   }
  }
 }
 if (HandleBuffer != NULL) {
   gBS->FreePool (HandleBuffer);
 }
}
```

7.3.16 EFI_BOOT_SERVICES.LocateProtocol()

Summary

Returns the first protocol instance that matches the given protocol.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_LOCATE_PROTOCOL) (
  IN EFI_GUID                         *Protocol,
  IN VOID                             *Registration OPTIONAL,
  OUT VOID                            **Interface
 );
```

Parameters

Protocol
Provides the protocol to search for.

Registration
Optional registration key returned from *EFI_BOOT_SERVICES.RegisterProtocolNotify()* . If *Registration* is NULL, then it is ignored.

Interface
On return, a pointer to the first interface that matches *Protocol* and *Registration*.

Description

The LocateProtocol() function finds the first device handle that support *Protocol*, and returns a pointer to the protocol interface from that handle in *Interface*. If no protocol instances are found, then *Interface* is set to NULL.

If *Interface* is NULL, then EFI_INVALID_PARAMETER is returned.

If *Protocol* is NULL, then EFI_INVALID_PARAMETER is returned.

If *Registration* is NULL, and there are no handles in the handle database that support *Protocol*, then EFI_NOT_FOUND is returned.

If *Registration* is not NULL, and there are no new handles for *Registration*, then EFI_NOT_FOUND is returned.

Status Codes Returned

EFI_SUCCESS	A protocol instance matching *Protocol* was found and returned in *Interface*.
EFI_INVALID_PARAMETER	*Interface* is NULL. *Protocol* is NULL.
EFI_NOT_FOUND	No protocol instances were found that match Protocol and *Registration*.

7.3.17 EFI_BOOT_SERVICES.InstallMultipleProtocolInterfaces()

Summary

Installs one or more protocol interfaces into the boot services environment.

Prototype

```
typedef
EFI_STATUS
EFIAPI \*EFI_INSTALL_MULTIPLE_PROTOCOL_INTERFACES) (
   IN OUT EFI_HANDLE                               *Handle,
   ...
   );
```

Parameters

Handle

The pointer to a handle to install the new protocol interfaces on, or a pointer to NULL if a new handle is to be allocated.

... A variable argument list containing pairs of protocol GUIDs and protocol interfaces.

Description

This function installs a set of protocol interfaces into the boot services environment. It removes arguments from the variable argument list in pairs. The first item is always a pointer to the protocol's GUID, and the second item is always a pointer to the protocol's interface. These pairs are used to call the boot service, see *EFI_BOOT_SERVICES.InstallProtocolInterface()* to add a protocol interface to *Handle*. If *Handle* is NULL on entry, then a new handle will be allocated. The pairs of arguments are removed in order from the variable argument list until a NULL protocol GUID value is found. If any errors are generated while the protocol interfaces are being installed, then all the protocols installed prior to the error will be uninstalled with the boot service

> *EFI_BOOT_SERVICES.UninstallProtocolInterface()* before the error is returned. The same GUID cannot be installed more than once onto the same handle.

It is illegal to have two handles in the handle database with identical device paths. This service performs a test to guarantee a duplicate device path is not inadvertently installed on two different handles. Before any protocol interfaces are installed onto Handle, the list of GUID/pointer pair parameters are searched to see if a Device Path Protocol instance is being installed. If a Device Path Protocol instance is going to be installed onto Handle, then a check is made to see if a handle is already present in the handle database with an identical Device Path Protocol instance. If an identical Device Path Protocol instance is already present in the handle database, then no protocols are installed onto Handle, and EFI_ALREADY_STARTED is returned.

Status Codes Returned

EFI_SUCCESS	All the protocol interfaces were installed.
EFI_ALREADY_STARTED	A Device Path Protocol instance was passed in that is already present in the handle database.
EFI_OUT_OF_RESOURCES	There was not enough memory in pool to install all the protocols.
EFI_INVALID_PARAMETER	*Handle* is NULL.
EFI_INVALID_PARAMETER	*Protocol* is already installed on the handle specified by *Handle*.

7.3.18 EFI_BOOT_SERVICES.UninstallMultipleProtocolInterfaces()

Summary

Removes one or more protocol interfaces into the boot services environment.

Prototype

```
typedef
EFI_STATUS
EFIAPI *EFI_UNINSTALL_MULTIPLE_PROTOCOL_INTERFACES) (
   IN EFI_HANDLE Handle,
   ...
  );
```

Parameters

Handle
The handle to remove the protocol interfaces from.

… A variable argument list containing pairs of protocol GUIDs and protocol interfaces.

Description

This function removes a set of protocol interfaces from the boot services environment. It removes arguments from the variable argument list in pairs. The first item is always a pointer to the protocol's GUID, and the second item is always a pointer to the protocol's interface. These pairs are used to call the boot service *EFI_BOOT_SERVICES.UninstallProtocolInterface()* to remove a protocol interface from Handle. The pairs of arguments are removed in order from the variable argument list until a NULL protocol GUID value is found. If all of the protocols are uninstalled from Handle, then EFI_SUCCESS is returned. If any errors are generated while the protocol interfaces are being uninstalled, then the protocols uninstalled prior to the error will be reinstalled with the boot service *EFI_BOOT_SERVICES.InstallProtocolInterface()* and the status code EFI_INVALID_PARAMETER is returned.

Status Codes Returned

EFI_SUCCESS	All the protocol interfaces were removed.
EFI_INVALID_PARAMETER	One of the protocol interfaces was not previously installed on Handle.

7.4 Image Services

Three types of images can be loaded: UEFI applications written (*UEFI Applications* , UEFI boot services drivers (*UEFI Drivers*), and EFI runtime drivers (*UEFI Drivers*) . A UEFI OS Loader (*UEFI OS Loaders*) is a type of UEFI application. The most significant difference between these image types is the type of memory into which they are loaded by the firmware's loader. See the Table, below, *Image Type Differences Summary* summarizes the differences between images.

Table 7.30: Image Type Differences Summary

	UEFI Application	**UEFI Boot Service Driver**	**UEFI Runtime Driver**
Description	A transient application that is loaded during boot services time. UEFI applications are either unloaded when they complete (see *UEFI Applications* , or they take responsibility for the continued operation of the system via ExitBootServices() (see *UEFI OS Loaders* . The UEFI applications are loaded in sequential order by the boot manager, but one UEFI application may dynamically load another.	A program that is loaded into boot services memory and stays resident until boot services terminate. See *UEFI Drivers* .	A program that is loaded into runtime services memory and stays resident during runtime. The memory required for a UEFI runtime services driver must be performed in a single memory allocation, and marked as EfiRuntimeServicesData. (Note that the memory only stays resident when booting an EFI-compatible operating system. Legacy operating systems will reuse the memory.) See *UEFI Drivers* .
Loaded into memory type	EfiLoaderCode, EfiLoaderData	EfiBootServicesCode, EfiBootServicesData	EfiRuntimeServicesCode, EfiRuntimeServicesData
Default pool allocations from memory type	EfiLoaderData	EfiBootServicesData	EfiRuntimeServicesData
Exit behavior	When an application exits, firmware frees the memory used to hold its image.	When a UEFI boot service driver exits with an error code, firmware frees the memory used to hold its image. When a UEFI boot service driver's entry point completes with EFI_SUCCESS, the image is retained in memory.	When a UEFI runtime driver exits with an error code, firmware frees the memory used to hold its image. When a UEFI runtime services driver's entry point completes with EFI_SUCCESS, the image is retained in memory.

continues on next page

Table 7.30 – continued from previous page

Notes	This type of image would not install any protocol interfaces or handles.	This type of image would typically use InstallProtocolInterface().	A UEFI runtime driver can only allocate runtime memory during boot services time. Due to the complexity of performing a virtual relocation for a runtime image, this driver type is discouraged unless it is absolutely required.

Most UEFI images are loaded by the boot manager. When a UEFI application or UEFI driver is installed, the installation procedure registers itself with the boot manager for loading. However, in some cases a UEFI application or UEFI driver may want to programmatically load and start another UEFI image. This can be done with the *EFI_BOOT_SERVICES.LoadImage()* and *EFI_BOOT_SERVICES.StartImage()* interfaces. UEFI drivers may only load UEFI applications during the UEFI driver's initialization entry point. The Table, below, *Image Functions* lists the functions that make up Image Services.

Table 7.31: Image Functions

Name	**Type**	**Description**
LoadImage	Boot	Loads an EFI image into memory.
StartImage	Boot	Transfers control to a loaded image's entry point.
UnloadImage	Boot	Unloads an image.
EFI_IMAGE_ENTRY_POINT	Boot	Prototype of an EFI Image's entry point.
Exit	Boot	Exits the image's entry point.
ExitBootServices	Boot	Terminates boot services.

The Image boot services have been modified to take advantage of the information that is now being tracked with the *EFI_BOOT_SERVICES.OpenProtocol()* and *EFI_BOOT_SERVICES.CloseProtocol()* boot services. Since the usage of protocol interfaces is being tracked with these new boot services, it is now possible to automatically close protocol interfaces when a UEFI application or a UEFI driver is unloaded or exited.

7.4.1 EFI_BOOT_SERVICES.LoadImage()

Summary

Loads an EFI image into memory.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_IMAGE_LOAD) (
   IN BOOLEAN                       BootPolicy,
   IN EFI_HANDLE                    ParentImageHandle,
   IN EFI_DEVICE_PATH_PROTOCOL      *DevicePath   OPTIONAL,
   IN VOID                          *SourceBuffer OPTIONAL
   IN UINTN                         SourceSize,
   OUT EFI_HANDLE                   *ImageHandle
   );
```

Parameters

BootPolicy

If **TRUE**, indicates that the request originates from the boot manager, and that the boot manager is attempting to load *DevicePath* as a boot selection. Ignored if *SourceBuffer* is not NULL.

ParentImageHandle
The caller's image handle. Type EFI_HANDLE is defined in the *EFI_BOOT_SERVICES.InstallProtocolInterface()* function description. This field is used to initialize the *ParentHandle* field of the *EFI Loaded Image Protocol* for the image that is being loaded.

DevicePath
The *DeviceHandle* specific file path from which the image is loaded. EFI_DEVICE_PATH_PROTOCOL is defined in *EFI Device Path Protocol* .

SourceBuffer
If not NULL, a pointer to the memory location containing a copy of the image to be loaded.

SourceSize
The size in bytes of SourceBuffer. Ignored if *SourceBuffer* is NULL.

ImageHandle
Pointer to the returned image handle that is created when the image is successfully loaded. Type EFI_HANDLE is defined in the InstallProtocolInterface() function description.

#define EFI_HII_PACKAGE_LIST_PROTOCOL_GUID \
  { 0x6a1ee763, 0xd47a, 0x43b4, \
  { 0xaa, 0xbe, 0xef, 0x1d, 0xe2, 0xab, 0x56, 0xfc } }

typedef EFI_HII_PACKAGE_LIST_HEADER *EFI_HII_PACKAGE_LIST_PROTOCOL;
```

Description

The LoadImage() function loads an EFI image into memory and returns a handle to the image. The image is loaded in one of two ways.

- If *SourceBuffer* is not NULL, the function is a memory-to-memory load in which *SourceBuffer* points to the image to be loaded and *SourceSize* indicates the image's size in bytes. In this case, the caller has copied the image into *SourceBuffer* and can free the buffer once loading is complete. The DevicePath is optional in this case. A DevicePath should still be provided since certain portions of firmware may use it to make certain security policy decisions.
- If *SourceBuffer* is NULL, the function is a file copy operation that uses the *EFI_SIMPLE_FILE_SYSTEM_PROTOCOL* .

  If there is no instance of *EFI_SIMPLE_FILE_SYSTEM_PROTOCOL* associated with file path, then this function will attempt to use EFI_LOAD_FILE_PROTOCOL (*BootPolicy* is **TRUE**) or EFI_LOAD_FILE2_PROTOCOL, and then EFI_LOAD_FILE_PROTOCOL (*BootPolicy* is **FALSE**).

In all cases, this function will use the instance of these protocols associated with the handle that most closely matches *DevicePath* will be used. See the boot service description for more information on how the closest handle is located.

- In the case of EFI_SIMPLE_FILE_SYSTEM_PROTOCOL, the path name from the File Path Media Device Path node(s) of *DevicePath* is used.
- In the case of EFI_LOAD_FILE_PROTOCOL, the remaining device path nodes of DevicePath and the *BootPolicy* flag are passed to the *EFI_LOAD_FILE_PROTOCOL* function. The default image responsible for booting is loaded when DevicePath specifies only the device (and there are no further device nodes). For more information see the discussion of *EFI_LOAD_FILE_PROTOCOL* .
- In the case of EFI_LOAD_FILE2_PROTOCOL, the behavior is the same as above, except that it is only used if *BootOption* is **FALSE**. For more information, see the discussion of the EFI_LOAD_FILE2_PROTOCOL.
- If the platform supports driver signing, as specified in *Image Execution Information Table* and the image signature is not valid, then information about the image is recorded in the EFI_IMAGE_EXECUTION_INFO_TABLE

(see Using the Image Execution Information Table in section 32.4.2. {cross-reference needed} and EFI_SECURITY_VIOLATION is returned.

- If the platform supports user authentication, as described in *User Identification* and loading of images on the specified *FilePath* is forbidden in the current user profile, then the information about the image is recorded (see Deferred Execution in *Image Execution Information Table* and EFI_SECURITY_VIOLATION is returned.

Once the image is loaded, firmware creates and returns an EFI_HANDLE that identifies the image and supports *EFI Loaded Image Protocol* and the EFI_LOADED_IMAGE_DEVICE_PATH_PROTOCOL. The caller may fill in the image's "load options" data, or add additional protocol support to the handle before passing control to the newly loaded image by calling *EFI_BOOT_SERVICES.StartImage()* . Also, once the image is loaded, the caller either starts it by calling StartImage() or unloads it by calling *EFI_BOOT_SERVICES.UnloadImage()* .

Once the image is loaded, LoadImage() installs EFI_HII_PACKAGE_LIST_PROTOCOL on the handle if the image contains a custom PE/COFF resource with the type 'HII'. The protocol's interface pointer points to the HII package list which is contained in the resource's data. The format of this is in *EFI_HII_PACKAGE_HEADER* .

Status Codes Returned

EFI_SUCCESS	Image was loaded into memory correctly.
EFI_NOT_FOUND	Both *SourceBuffer* and *DevicePath* are NULL.
EFI_INVALID_PARAMETER	One of the parameters has an invalid value.
EFI_INVALID_PARAMETER	*ImageHandle* is NULL.
EFI_INVALID_PARAMETER	*ParentImageHandle* is NULL.
EFI_INVALID_PARAMETER	*ParentImageHandle* is NULL.
EFI_UNSUPPORTED	The image type is not supported.
EFI_OUT_OF_RESOURCES	Image was not loaded due to insufficient resources.
EFI_LOAD_ERROR	Image was not loaded because the image format was corrupt or not understood.
EFI_DEVICE_ERROR	Image was not loaded because the device returned a read error.
EFI_ACCESS_DENIED	Image was not loaded because the platform policy prohibits the image from being loaded. NULL is returned in *ImageHandle*.
EFI_SECURITY_VIOLATION	Image was loaded and an *ImageHandle* was created with a valid EFI_LOADED_IMAGE_PROTOCOL. However, the current platform policy specifies that the image should not be started.

7.4.2 EFI_BOOT_SERVICES.StartImage()

Summary

Transfers control to a loaded image's entry point.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_IMAGE_START) (
   IN EFI_HANDLE                           ImageHandle,
   OUT UINTN                               *ExitDataSize,
   OUT CHAR16                              **ExitData OPTIONAL
   );
```

Parameters

ImageHandle
Handle of image to be started. Type EFI_HANDLE is defined in the *EFI_BOOT_SERVICES.InstallProtocolInterface()* function description.

ExitDataSize
Pointer to the size, in bytes, of *ExitData*. If *ExitData* is NULL, then this parameter is ignored and the contents of *ExitDataSize* are not modified.

ExitData
Pointer to a pointer to a data buffer that includes a Null-terminated string, optionally followed by additional binary data. The string is a description that the caller may use to further indicate the reason for the image's exit.

Description

The StartImage() function transfers control to the entry point of an image that was loaded by *EFI_BOOT_SERVICES.LoadImage()* . The image may only be started one time.

Control returns from StartImage() when the loaded image's EFI_IMAGE_ENTRY_POINT returns or when the loaded image calls *EFI_BOOT_SERVICES.Exit()* When that call is made, the ExitData buffer and *ExitDataSize* from Exit() are passed back through the *ExitData* buffer and *ExitDataSize* in this function. The caller of this function is responsible for returning the *ExitData* buffer to the pool by calling *EFI_BOOT_SERVICES.FreePool()* when the buffer is no longer needed. Using Exit() is similar to returning from the image's EFI_IMAGE_ENTRY_POINT except that Exit() may also return additional *ExitData*. Exit() function description defines clean up procedure performed by the firmware once loaded image returns control.

EFI 1.10 Extension

To maintain compatibility with UEFI drivers that are written to the *EFI 1.02 Specification*, StartImage() must monitor the handle database before and after each image is started. If any handles are created or modified when an image is started, then *EFI_BOOT_SERVICES.ConnectController()* must be called with the *Recursive parameter* set to **TRUE** for each of the newly created or modified handles before StartImage() returns.

Status Codes Returned

EFI_INVALID_PARAMETER	ImageHandle is either an invalid image handle or the image has already been initialized with StartImage
Exit code from image	Exit code from image.
EFI_SECURITY_VIOLATION	The current platform policy specifies that the image should not be started.

7.4.3 EFI_BOOT_SERVICES.UnloadImage()

Summary

Unloads an image.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_IMAGE_UNLOAD) (
   IN EFI_HANDLE           ImageHandle
   );
```

Parameters

ImageHandle
Handle that identifies the image to be unloaded.

Description

The UnloadImage() function unloads a previously loaded image.

There are three possible scenarios. If the image has not been started, the function unloads the image and returns EFI_SUCCESS.

If the image has been started and has an Unload() entry point, control is passed to that entry point. If the image's unload function returns EFI_SUCCESS, the image is unloaded; otherwise, the error returned by the image's unload function is returned to the caller. The image unload function is responsible for freeing all allocated memory and ensuring that there are no references to any freed memory, or to the image itself, before returning EFI_SUCCESS.

If the image has been started and does not have an Unload() entry point, the function returns EFI_UNSUPPORTED.

EFI 1.10 Extension

All of the protocols that were opened by ImageHandle using the boot service *EFI_BOOT_SERVICES.OpenProtocol()* are automatically closed with the boot service *EFI_BOOT_SERVICES.CloseProtocol()* . If all of the open protocols are closed, then EFI_SUCCESS is returned. If any call to CloseProtocol() fails, then the error code from CloseProtocol() is returned.

Status Codes Returned

EFI_SUCCESS	The image has been unloaded.
EFI_UNSUPPORTED	The image has been started, and does not support unload.
EFI_INVALID_PARAMETER	*ImageHandle* is not a valid image handle.
Exit code from Unload handler	Exit code from the image's unload function.

7.4.4 EFI_IMAGE_ENTRY_POINT

Summary

This is the declaration of an EFI image entry point. This can be the entry point to an application written to this specification, an EFI boot service driver, or an EFI runtime driver.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_IMAGE_ENTRY_POINT) (
   IN EFI_HANDLE                              ImageHandle,
   IN EFI_SYSTEM_TABLE                        *SystemTable
   );
```

Parameters

ImageHandle
Handle that identifies the loaded image. Type EFI_HANDLE is defined in the *EFI_BOOT_SERVICES.InstallProtocolInterface()* function description.

SystemTable
System Table for this image. Type EFI_SYSTEM_TABLE is defined in *EFI System Table*

Description

An image's entry point is of type EFI_IMAGE_ENTRY_POINT. After firmware loads an image into memory, control is passed to the image's entry point. The entry point is responsible for initializing the image. The image's *ImageHandle* is passed to the image. The *ImageHandle* provides the image with all the binding and data information it needs. This information is available through protocol interfaces. However, to access the protocol interfaces on *ImageHandle* requires access to boot services functions. Therefore, *EFI_BOOT_SERVICES.LoadImage()* passes to the EFI_IMAGE_ENTRY_POINT a *SystemTable* that is inherited from the current scope of LoadImage().

All image handles support the *EFI Loaded Image Protocol* and the EFI_LOADED_IMAGE_DEVICE_PATH_PROTOCOL. These protocol can be used to obtain information about the loaded image's state–for example, the device from which the image was loaded and the image's load options. In addition, the ImageHandle may support other protocols provided by the parent image.

If the image supports dynamic unloading, it must supply an unload function in the EFI_LOADED_IMAGE_PROTOCOL structure before returning control from its entry point.

In general, an image returns control from its initialization entry point by calling *EFI_BOOT_SERVICES.Exit()* or by returning control from its entry point. If the image returns control from its entry point, the firmware passes control to Exit() using the return code as the *ExitStatus* parameter to Exit().

See Exit() below for entry point exit conditions.

7.4.5 EFI_BOOT_SERVICES.Exit()

Summary

Terminates a loaded EFI image and returns control to boot services.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_EXIT) (
   IN EFI_HANDLE                      ImageHandle,
   IN EFI_STATUS                      ExitStatus,
   IN UINTN                           ExitDataSize,
   IN CHAR16                          *ExitData OPTIONAL
   );
```

Parameters

ImageHandle

Handle that identifies the image. This parameter is passed to the image on entry.

ExitStatus

The image's exit code.

ExitDataSize

The size, in bytes, of *ExitData*. Ignored if *ExitStatus* is EFI_SUCCESS.

ExitData

Pointer to a data buffer that includes a Null-terminated string, optionally followed by additional binary data. The string is a description that the caller may use to further indicate the reason for the image's exit. *ExitData* is only valid if *ExitStatu* is something other than EFI_SUCCESS. The *ExitData* buffer must be allocated by calling *EFI_BOOT_SERVICES.AllocatePool()* .

Description

The Exit() function terminates the image referenced by *ImageHandle* and returns control to boot services. This function may not be called if the image has already returned from its entry point (*EFI_IMAGE_ENTRY_POINT*) or if it has loaded any child images that have not exited (all child images must exit before this image can exit).

Using Exit() is similar to returning from the image's EFI_IMAGE_ENTRY_POINT except that Exit() may also return additional ExitData.

When an application exits a compliant system, firmware frees the memory used to hold the image. The firmware also frees its references to the *ImageHandle* and the handle itself. Before exiting, the application is responsible for freeing any resources it allocated. This includes memory (pages and/or pool), open file system handles, and so forth. The only exception to this rule is the ExitData buffer, which must be freed by the caller of *EFI_BOOT_SERVICES.StartImage()* . (If the buffer is needed, firmware must allocate it by calling *EFI_BOOT_SERVICES.AllocatePool()* and must return a pointer to it to the caller of StartImage().)

When an EFI boot service driver or runtime service driver exits, firmware frees the image only if the *ExitStatus* is an error code; otherwise the image stays resident in memory. The driver must not return an error code if it has installed any protocol handlers or other active callbacks into the system that have not (or cannot) be cleaned up. If the driver exits with an error code, it is responsible for freeing all resources before exiting. This includes any allocated memory (pages and/or pool), open file system handles, and so forth.

It is valid to call Exit() or UnloadImage() for an image that was loaded by *EFI_BOOT_SERVICES.LoadImage()* before calling *EFI_BOOT_SERVICES.StartImage()* . This will free the image from memory without having started it.

EFI 1.10 Extension

If *ImageHandle* is a UEFI application, then all of the protocols that were opened by *ImageHandle* using the boot service *EFI_BOOT_SERVICES.OpenProtocol()* are automatically closed with the boot service *EFI_BOOT_SERVICES.CloseProtocol()* . If *ImageHandle* is a UEFI boot service driver or UEFI runtime service driver, and *ExitStatus* is an error code, then all of the protocols that were opened by *ImageHandle* using the boot service OpenProtocol() are automatically closed with the boot service CloseProtocol(). If *ImageHandle* is a UEFI boot service driver or UEFI runtime service driver, and *ExitStatus* is not an error code, then no protocols are automatically closed by this service.

Status Codes Returned

(Does not return.)	Image exit. Control is returned to the StartImage() call that invoked the image specified by *ImageHandle*.
EFI_SUCCESS	The image specified by *ImageHandle* was unloaded. This condition only occurs for images that have been loaded with LoadImage() but have not been started with StartImage().
EFI_INVALID_PARAMETER	The image specified by *ImageHandle* has been loaded and started with LoadImage() and StartImage(), but the image is not the currently executing image.

7.4.6 EFI_BOOT_SERVICES.ExitBootServices()

Summary

Terminates all boot services.

Prototype

```
EFI_STATUS
(EFIAPI *EFI_EXIT_BOOT_SERVICES) (
  IN EFI_HANDLE                         ImageHandle,
  IN UINTN                              MapKey
  );
```

Parameters

ImageHandle

Handle that identifies the exiting image. Type *EFI_HANDLE* is defined in the *Image Execution Information Table* function description.

MapKey

Key to the latest memory map.

Description

The ExitBootServices() function is called by the currently executing UEFI OS loader image to terminate all boot services. On success, the UEFI OSloader becomes responsible for the continued operation of the system. All events from the EFI_EVENT_GROUP_BEFORE_EXIT_BOOT_SERVICES and EFI_EVENT_GROUP_EXIT_BOOT_SERVICES event notification groups as well as events of type EVT_SIGNAL_EXIT_BOOT_SERVICES must be signaled before ExitBootServices() returns EFI_SUCCESS. The events are only signaled once even if ExitBootServices() is called multiple times.

A UEFI OS loader must ensure that it has the system's current memory map at the time it calls ExitBootServices(). This is done by passing in the current memory map's MapKey value as returned by *EFI_BOOT_SERVICES.GetMemoryMap()* . Care must be taken to ensure that the memory map does not change between these two calls. It is suggested that GetMemoryMap() be called immediately before calling ExitBootServices(). If MapKey value is incorrect, ExitBootServices() returns EFI_INVALID_PARAMETER and GetMemoryMap() with ExitBootServices() must be called again. Firmware implementation may choose to do a partial shutdown of the boot services during the first call to ExitBootServices(). A UEFI OS loader should not make calls to any boot service function other than Memory Allocation Services after the first call to ExitBootServices().

On success, the UEFI OS loader owns all available memory in the system. In addition, the UEFI OS loader can treat all memory in the map marked as EfiBootServicesCode and EfiBootServicesData as available free memory. No further calls to boot service functions or EFI device-handle-based protocols may be used, and the boot services watchdog timer is disabled. On success, several fields of the EFI System Table should be set to NULL. These include *ConsoleInHandle*, *ConIn*, *ConsoleOutHandle*, *ConOut*, *StandardErrorHandle*, *StdErr*, and *BootServicesTable*. In addition, since fields of the EFI System Table are being modified, the 32-bit CRC for the EFI System Table must be recomputed.

Firmware must guarantee the following order of processing:

- EFI_EVENT_GROUP_BEFORE_EXIT_BOOT_SERVICES handlers are called.
- Timer services are deactivated (timer event activity stopped).
- EVT_SIGNAL_EXIT_BOOT_SERVICES and EFI_EVENT_GROUP_BEFORE_EXIT_BOOT_SERVICES handlers are called.

NOTE: The EVT_SIGNAL_EXIT_BOOT_SERVICES event type and EFI_EVENT_GROUP_BEFORE_EXIT_BOOT_SERVICES event group are functionally equivalent. Firmware does not distinguish between the two while ordering the handlers.

Refer to EFI_EVENT_GROUP_EXIT_BOOT_SERVICES description in the EFI_BOOT_SERVICES.CreateEventEx() section above for additional restrictions on EXIT_BOOT_SERVICES handlers.

Status Codes Returned

EFI_SUCCESS	Boot services have been terminated.
EFI_INVALID_PARAMETER	*MapKey* is incorrect.

7.5 Miscellaneous Boot Services

This section contains the remaining function definitions for boot services not defined elsewhere but which are required to complete the definition of the EFI environment. The Table, below, lists the Miscellaneous Boot Services Functions.

Table 7.37: Miscellaneous Boot Services Functions

Name	Type	Description
SetWatchDogTimer	Boot	Resets and sets a watchdog timer used during boot services time.

continues on next page

Table 7.37 – continued from previous page

Stall	Boot	Stalls the processor.
CopyMem	Boot	Copies the contents of one buffer to another buffer.
SetMem	Boot	Fills a buffer with a specified value.
GetNextMonotonicCount	Boot	Returns a monotonically increasing count for the platform.
InstallConfigurationTable	Boot	Adds, updates, or removes a configuration table from the EFI System Table.
CalculateCrc32	Boot	Computes and returns a 32-bit CRC for a data buffer.

The *EFI_BOOT_SERVICES.CalculateCrc32()* service was added because there are several places in EFI that 32-bit CRCs are used. These include the EFI System Table, the EFI Boot Services Table, the EFI Runtime Services Table, and the GUID Partition Table (GPT) structures. The CalculateCrc32() service allows new 32-bit CRCs to be computed, and existing 32-bit CRCs to be validated.

7.5.1 EFI_BOOT_SERVICES.SetWatchdogTimer()

Summary

Sets the system's watchdog timer.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SET_WATCHDOG_TIMER) ((
   IN UINTN                              Timeout,
   IN UINT64                             WatchdogCode,
   IN UINTN                              DataSize,
   IN CHAR16                             *WatchdogData OPTIONAL
   );
```

Parameters

Timeout

The number of seconds to set the watchdog timer to. A value of zero disables the timer.

WatchdogCode

The numeric code to log on a watchdog timer timeout event. The firmware reserves codes 0x0000 to 0xFFFF. Loaders and operating systems may use other timeout codes.

DataSize

The size, in bytes, of *WatchdogData*.

WatchdogData

A data buffer that includes a Null-terminated string, optionally followed by additional binary data. The string is a description that the call may use to further indicate the reason to be logged with a watchdog event.

Description

The SetWatchdogTimer() function sets the system's watchdog timer.

If the watchdog timer expires, the event is logged by the firmware. The system may then either reset with the Runtime Service *ResetSystem()* or perform a platform specific action that must eventually cause the platform to be reset. The watchdog timer is armed before the firmware's boot manager invokes an EFI boot option. The watchdog must be set to a period of 5 minutes. The EFI Image may reset or disable the watchdog timer as needed. If control is returned to the firmware's boot manager, the watchdog timer must be disabled.

The watchdog timer is only used during boot services. On successful completion of *EFI_BOOT_SERVICES.ExitBootServices()* the watchdog timer is disabled.

The accuracy of the watchdog timer is +/- 1 second from the requested Timeout.

Status Codes Returned

EFI_SUCCESS	The timeout has been set.
EFI_INVALID_PARAMETER	The supplied *WatchdogCode* is invalid.
EFI_UNSUPPORTED	The system does not have a watchdog timer.
EFI_DEVICE_ERROR	The watch dog timer could not be programmed due to a hardware error.

7.5.2 EFI_BOOT_SERVICES.Stall()

Summary

Induces a fine-grained stall.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_STALL) (
   IN UINTN                Microseconds
   )
```

Parameters

Microseconds
The number of microseconds to stall execution.

Description

The Stall() function stalls execution on the processor for at least the requested number of microseconds. Execution of the processor is *not* yielded for the duration of the stall.

Status Codes Returned

EFI_SUCCESS	Execution was stalled at least the requested number of *Microseconds*.

7.5.3 EFI_BOOT_SERVICES.CopyMem()

Summary

The *CopyMem()* function copies the contents of one buffer to another buffer.

Prototype

```
typedef
VOID
(EFIAPI *EFI_COPY_MEM) (
   IN VOID                       *Destination,
   IN VOID                       *Source,
   IN UINTN                      Length
   );
```

Parameters

Destination
Pointer to the destination buffer of the memory copy.

Source
Pointer to the source buffer of the memory copy.

Length
Number of bytes to copy from Source to Destination.

Description

The CopyMem() function copies Length bytes from the buffer *Source* to the buffer *Destination*.

The implementation of CopyMem() must be reentrant, and it must handle overlapping *Source* and *Destination* buffers. This means that the implementation of CopyMem() must choose the correct direction of the copy operation based on the type of overlap that exists between the *Source* and *Destination* buffers. If either the *Source* buffer or the *Destination* buffer crosses the top of the processor's address space, then the result of the copy operation is unpredictable.

The contents of the *Destination* buffer on exit from this service must match the contents of the *Source* buffer on entry to this service. Due to potential overlaps, the contents of the *Source* buffer may be modified by this service. The following rules can be used to guarantee the correct behavior:

1. If *Destination* and *Source* are identical, then no operation should be performed.
2. If *Destination* > *Source* and *Destination* < (*Source* + *Length*), then the data should be copied from the *Source* buffer to the *Destination* buffer starting from the end of the buffers and working toward the beginning of the buffers.
3. Otherwise, the data should be copied from the *Source* buffer to the *Destination* buffer starting from the beginning of the buffers and working toward the end of the buffers.

Status Codes Returned

None.

7.5.4 EFI_BOOT_SERVICES.SetMem()

Summary

The *SetMem()* function fills a buffer with a specified value.

Prototype

```
typedef
VOID
EFIAPI *EFI_SET_MEM) (
   IN VOID                             *Buffer,
   IN UINTN                            Size,
   IN UINT8                            Value
   );
```

Parameters

Buffer
Pointer to the buffer to fill.

Size
Number of bytes in Buffer to fill.

Value

Value to fill Buffer with.

Description

This function fills Size bytes of*Buffer*with *Value*. The implementation of SetMem() must be reentrant. If *Buffer* crosses the top of the processor's address space, the result of the SetMem() operation is unpredictable.

Status Codes Returned

None.

7.5.5 EFI_BOOT_SERVICES.GetNextMonotonicCount()

Summary

Returns a monotonically increasing count for the platform.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_GET_NEXT_MONOTONIC_COUNT) (
   OUT UINT64                       *Count
   );
```

Parameters

Count

Pointer to returned value.

Description

The GetNextMonotonicCount() function returns a 64-bit value that is numerically larger then the last time the function was called.

The platform's monotonic counter is comprised of two parts: the high 32 bits and the low 32 bits. The low 32-bit value is volatile and is reset to zero on every system reset. It is increased by 1 on every call to GetNextMonotonicCount(). The high 32-bit value is nonvolatile and is increased by one on whenever the system resets or the low 32-bit counter overflows.

Status Codes Returned

EFI_SUCCESS	The next monotonic count was returned.
EFI_DEVICE_ERROR	The device is not functioning properly.
EFI_INVALID_PARAMETER	*Count* is NULL.

7.5.6 EFI_BOOT_SERVICES.InstallConfigurationTable()

Summary

Adds, updates, or removes a configuration table entry from the EFI System Table.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_INSTALL_CONFIGURATION_TABLE) (
   IN EFI_GUID                              *Guid,
   IN VOID                                  *Table
   );
```

Parameters

Guid

A pointer to the GUID for the entry to add, update, or remove.

Table

A pointer to the configuration table for the entry to add, update, or remove. May be NULL.

Description

The InstallConfigurationTable() function is used to maintain the list of configuration tables that are stored in the EFI System Table. The list is stored as an array of (GUID, Pointer) pairs. The list must be allocated from pool memory with *PoolType* set to EfiRuntimeServicesData.

If *Guid* is NULL, EFI_INVALID_PARAMETER is returned. If Guid is valid, there are four possibilities:

- If *Guid* is not present in the System Table, and *Table* is not NULL, then the (Guid, Table) pair is added to the System Table. See Note below.
- If *Guid* is not present in the System Table, and *Table* is NULL, then EFI_NOT_FOUND is returned.
- If *Guid* is present in the System Table, and *Table* is not NULL, then the (Guid, Table) pair is updated with the new Table value.
- If *Guid* is present in the System Table, and *Table* is NULL , then the entry associated with Guid is removed from the System Table.

If an add, modify, or remove operation is completed, then EFI_SUCCESS is returned.

Note: *If there is not enough memory to perform an add operation, then* EFI_OUT_OF_RESOURCES *is returned.*

Status Codes Returned

EFI_SUCCESS	The (*Guid, Table*) pair was added, updated, or removed.
EFI_INVALID_PARAMETER	*Guid* is NULL.
EFI_NOT_FOUND	An attempt was made to delete a nonexistent entry.
EFI_OUT_OF_RESOURCES	There is not enough memory available to complete the operation.

7.5.7 EFI_BOOT_SERVICES.CalculateCrc32()

Summary

Computes and returns a 32-bit CRC for a data buffer.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_CALCULATE_CRC32)
   IN VOID                          *Data,
   IN UINTN                         DataSize,
```

(continues on next page)

(continued from previous page)

```
  OUT UINT32                        *Crc32
  );
```

Parameters

Data

A pointer to the buffer on which the 32-bit CRC is to be computed.

DataSize

The number of bytes in the buffer *Data*.

Crc32

The 32-bit CRC that was computed for the data buffer specified by *Data* and DataSize.

Description

This function computes the 32-bit CRC for the data buffer specified by *Data and *DataSize*. If the 32-bit CRC is computed, then it is returned in *Crc32* and EFI_SUCCESS is returned.

If *Data* is NULL, then EFI_INVALID_PARAMETER is returned.

If *Crc32* is NULL, then EFI_INVALID_PARAMETER is returned.

If *DataSize* is 0, then EFI_INVALID_PARAMETER is returned.

Status Codes Returned

EFI_SUCCESS	The 32-bit CRC was computed for the data buffer and returned in *Crc32*.
EFI_INVALID_PARAMETER	*Data* is NULL.
EFI_INVALID_PARAMETER	*Crc32* is NULL.
EFI_INVALID_PARAMETER	*DataSize* is 0.

CHAPTER

EIGHT

SERVICES — RUNTIME SERVICES

This section discusses the fundamental services that are present in a compliant system. The services are defined by interface functions that may be used by code running in the EFI environment. Such code may include protocols that manage device access or extend platform capability, as well as applications running in the preboot environment and EFI OS loaders.

Two types of services are described here:

- **Boot Services**. Functions that are available *before* a successful call to EFI_BOOT_SERVICES.ExitBootServices(), described in *EFI_BOOT_SERVICES.ExitBootServices()* .
- **Runtime Services**. Functions that are available before and after any call to *ExitBootServices()*. These functions are described in this section.

During boot, system resources are owned by the firmware and are controlled through boot services interface functions. These functions can be characterized as "global" or "handle-based." The term "global" simply means that a function accesses system services and is available on all platforms (since all platforms support all system services). The term "handle-based" means that the function accesses a specific device or device functionality and may not be available on some platforms (since some devices are not available on some platforms). Protocols are created dynamically. This section discusses the "global" functions and runtime functions; subsequent sections discuss the "handle-based."

UEFI applications (including UEFI OS loaders) must use boot services functions to access devices and allocate memory. On entry, an image is provided a pointer to a system table which contains the Boot Services dispatch table and the default handles for accessing the console. All boot services functionality is available until a UEFI OS loader loads enough of its own environment to take control of the system's continued operation and then terminates boot services with a call to ExitBootServices().

In principle, the ExitBootServices() call is intended for use by the operating system to indicate that its loader is ready to assume control of the platform and all platform resource management. Thus boot services are available up to this point to assist the UEFI OS loader in preparing to boot the operating system. Once the UEFI OS loader takes control of the system and completes the operating system boot process, only runtime services may be called. Code other than the UEFI OS loader, however, may or may not choose to call ExitBootServices(). This choice may in part depend upon whether or not such code is designed to make continued use of EFI boot services or the boot services environment.

The rest of this section discusses individual functions. Runtime Services fall into these categories:

- Runtime Rules and Restrictions (*Runtime Services Rules and Restrictions*)
- Variable Services (*Exception for Machine Check, INIT, and NMI*)
- Time Services (*Time Services*)
- Virtual Memory Services (*Virtual Memory Services*)
- Miscellaneous Services (*Miscellaneous Runtime Services*)

8.1 Runtime Services Rules and Restrictions

All of the Runtime Services may be called with interrupts enabled if desired. The Runtime Service functions will internally disable interrupts when it is required to protect access to hardware resources. The interrupt enable control bit will be returned to its entry state after the access to the critical hardware resources is complete.

All callers of Runtime Services are restricted from calling the same or certain other Runtime Service functions prior to the completion and return of a previous Runtime Service call. These restrictions apply to:

- Runtime Services that have been interrupted
- Runtime Services that are active on another processor.

Callers are prohibited from using certain other services from another processor or on the same processor following an interrupt as specified in *Rules for Reentry Into Runtime Services*. For this table 'Busy' is defined as the state when a Runtime Service has been entered and has not returned to the caller.

The consequence of a caller violating these restrictions is undefined except for certain special cases described below.

Table 8.1: Rules for Reentry Into Runtime Services

If previous call is busy in	**Forbidden to call**
Any	SetVirtualAddressMap()
ConvertPointer()	ConvertPointer()
SetVariable(), UpdateCapsule(), SetTime() SetWakeupTime(), GetNextHighMonotonicCount()	ResetSystem()
GetVariable() GetNextVariableName() SetVariable() QueryVariableInfo() UpdateCapsule() QueryCapsuleCapabilities() GetNextHighMonotonicCount()	GetVariable(), GetNextVariableName(), SetVariable(), QueryVariableInfo(), UpdateCapsule(), QueryCapsuleCapabilities(), GetNextHighMonotonicCount()
GetTime() SetTime() GetWakeupTime() SetWakeupTime()	GetTime() SetTime() GetWakeupTime() SetWakeupTime()

If any EFI_RUNTIME_SERVICES* calls are not supported for use by the OS at runtime, an EFI_RT_PROPERTIES_TABLE configuration table should be published describing which runtime services are supported at runtime (*EFI Configuration Table & Properties Table*). Note that this is merely a hint to the OS, which it is free to ignore, and so the platform is still required to provide callable implementations of unsupported runtime services that simply return EFI_UNSUPPORTED.

8.1.1 Exception for Machine Check, INIT, and NMI

Certain asynchronous events (e.g., NMI on IA-32 and x64 systems, Machine Check and INIT on Itanium systems) can not be masked and may occur with any setting of interrupt enabled. These events also may require OS level handler's involvement that may involve the invocation of some of the runtime services (see below).

If SetVirtualAddressMap() has been called, all calls to runtime services after Machine Check, INIT, or NMI, must be made using the virtual address map set by that call.

A Machine Check may have interrupted a runtime service (see below). If the OS determines that the Machine Check is recoverable, the OS level handler must follow the normal restrictions in the Table *Rules for Reentry Into Runtime Services*.

If the OS determines that the Machine Check is non-recoverable, the OS level handler may ignore the normal restrictions and may invoke the runtime services described in the Table *Functions that may be called after Machine Check, INIT and NMI* even in the case where a previous call was busy. The system firmware will honor the new runtime service call(s) and the operation of the previous interrupted call is not guaranteed. Any interrupted runtime functions will not be restarted.

The INIT and NMI events follow the same restrictions.

NOTE: *On Itanium systems, the OS Machine Check Handler must not call ResetSystem(). If a reset is required, the OS Machine Check Handler may request SAL to reset upon return to SAL_CHECK.*

The platform implementations are required to clear any runtime services in progress in order to enable the OS handler to invoke these runtime services even in the case where a previous call was busy. In this case, the proper operation of the original interrupted call is not guaranteed.

Table 8.2: Functions that may be called after Machine Check, INIT and NMI

Function	Called after Machine Check, INIT and NMI
GetTime()	Yes, even if previously busy
GetVariable()	Yes, even if previously busy
GetNextVariableName()	Yes, even if previously busy
QueryVariableInfo()	Yes, even if previously busy
SetVariable()	Yes, even if previously busy
UpdateCapsule()	Yes, even if previously busy
QueryCapsuleCapabilities()	Yes, even if previously busy
ResetSystem()	Yes, even if previously busy

8.2 Variable Services

Variables are defined as key/value pairs that consist of identifying information plus attributes (the key) and arbitrary data (the value). Variables are intended for use as a means to store data that is passed between the EFI environment implemented in the platform and EFI OS loaders and other applications that run in the EFI environment.

Although the implementation of variable storage is not defined in this specification, variables must be persistent in most cases. This implies that the EFI implementation on a platform must arrange it so that variables passed in for storage are retained and available for use each time the system boots, at least until they are explicitly deleted or overwritten.

Provision of this type of nonvolatile storage may be very limited on some platforms, so variables should be used sparingly in cases where other means of communicating information cannot be used.

The Table below lists the variable services functions described in this section:

Variable Services Functions

Table 8.3: Variable Services Functions

Name	Type	Description
GetVariable	Runtime	Returns the value of a variable.
GetNextVariableName	Runtime	Enumerates the current variable names.
SetVariable	Runtime	Sets the value of a variable.
QueryVariableInfo	Runtime	Returns information about the EFI variables

8.2.1 GetVariable()

Summary

Returns the value of a variable.

Prototype

```
typedef
EFI_STATUS
GetVariable (
  IN CHAR16           *VariableName,
  IN EFI_GUID         *VendorGuid,
  OUT UINT32          *Attributes OPTIONAL,
  IN OUT UINTN        *DataSize,
  OUT VOID            *Data OPTIONAL
 );
```

Parameters

VariableName
A Null-terminated string that is the name of the vendor's variable.

VendorGuid
A unique identifier for the vendor. Type EFI_GUID is defined in the :ref:` efi-boot-services-installprotocolinterface` function description.

Attributes
If not NULL, a pointer to the memory location to return the attributes bitmask for the variable. See "Related Definitions." If not NULL, then *Attributes* is set on output both when *EFI_SUCCESS* and when EFI_BUFFER_TOO_SMALL is returned.

DataSize
On input, the size in bytes of the return Data buffer. On output the size of data returned in Data.

Data
The buffer to return the contents of the variable. May be NULL with a zero *DataSize* in order to determine the size buffer needed.

Related Definitions

```
//*******************************************************
// Variable Attributes
//*******************************************************
#define EFI_VARIABLE_NON_VOLATILE                           0x00000001
#define EFI_VARIABLE_BOOTSERVICE_ACCESS                     0x00000002
#define EFI_VARIABLE_RUNTIME_ACCESS                         0x00000004
#define EFI_VARIABLE_HARDWARE_ERROR_RECORD                  0x00000008 \
//This attribute is identified by the mnemonic 'HR' elsewhere
//in this specification.
#define EFI_VARIABLE_AUTHENTICATED_WRITE_ACCESS             0x00000010
//NOTE: EFI_VARIABLE_AUTHENTICATED_WRITE_ACCESS is deprecated
//and should be considered reserved.
#define EFI_VARIABLE_TIME_BASED_AUTHENTICATED_WRITE_ACCESS \0x00000020
#define EFI_VARIABLE_APPEND_WRITE                           0x00000040
#define EFI_VARIABLE_ENHANCED_AUTHENTICATED_ACCESS          0x00000080
//This attribute indicates that the variable payload begins
//with an EFI_VARIABLE_AUTHENTICATION_3 structure, and
//potentially more structures as indicated by fields of this
//structure. See definition below and in SetVariable().
```

Description

Each vendor may create and manage its own variables without the risk of name conflicts by using a unique VendorGuid. When a variable is set its Attributes are supplied to indicate how the data variable should be stored and maintained by the system. The attributes affect when the variable may be accessed and volatility of the data. If EFI_BOOT_SERVICES.ExitBootServices() has already been executed, data variables without the EFI_VARIABLE_RUNTIME_ACCESS attribute set will not be visible to GetVariable() and will return an EFI_NOT_FOUND error.

If the *Data* buffer is too small to hold the contents of the variable, the error *EFI_BUFFER_TOO_SMALL* is returned and DataSize is set to the required buffer size to obtain the data.

The EFI_VARIABLE_TIME_BASED_AUTHENTICATED_WRITE_ACCESS and the EFI_VARIABLE_ AUTHENTICATED_WRITE_ACCESS attributes may both be set in the returned *Attributes* bitmask parameter of a GetVariable() call, though it should be noted that the EFI_VARIABLE_AUTHENTICATED_WRITE_ACCESS attribute is deprecated and should no longer be used. The EFI_VARIABLE_APPEND_WRITE attribute will never be set in the returned *Attributes* bitmask parameter.

Variables stored with the EFI_VARIABLE_ENHANCED_AUTHENTICATED_ACCESS attribute set will return metadata in addition to variable data when GetVariable() is called. If a GetVariable() call indicates that this attribute is set, the GetVariable() payload must be interpreted according to the metadata headers. In addition to the headers described in SetVariable(), the following header is used to indicate what certificate may be currently associated with a variable.

```
//
// EFI_VARIABLE_AUTHENTICATION_3_CERT_ID descriptor
//
// An extensible structure to identify a unique x509 cert
// associated with a given variable
//
#define EFI_VARIABLE_AUTHENTICATION_3_CERT_ID_SHA256 1

typedef struct {
   UINT8          Type;
```

(continues on next page)

(continued from previous page)

```
   UINT32         IdSize;
   // UINT8       Id[IdSize];
}   EFI_VARIABLE_AUTHENTICATION_3_CERT_ID;
```

Type
Identifies the type of ID that is returned and how the ID should be interpreted.

IdSize
Indicates the size of the Id buffer that follows this field in the structure.

Id (Not a formal structure member)
This is a unique identifier for the associated certificate as defined by the Type field. For CERT_ID_SHA256, the buffer will be a SHA-256 digest of the tbsCertificate (To Be Signed Certificate data defined in x509) data for the cert.

When the attribute EFI_VARIABLE_ENHANCED_AUTHENTICATED_ACCESS is set, the Data buffer shall be interpreted as follows:

// NOTE: "||" indicates concatenation.

// Example: EFI_VARIABLE_AUTHENTICATION_3_TIMESTAMP_TYPE

EFI_VARIABLE_AUTHENTICATION_3 || EFI_TIME || EFI_VARIABLE_AUTHENTICATION_3_CERT_ID || Data

// Example: *EFI_VARIABLE_AUTHENTICATION_3_NONCE_TYPE*

EFI_VARIABLE_AUTHENTICATION_3 || EFI_VARIABLE_AUTHENTICATION_3_NONCE || EFI_VARIABLE_AUTHENTICATION_3_CERT_ID || Data

NOTE: *The MetadataSize field of the EFI_VARIABLE_AUTHENTICATION_3 structure in each of these examples does not include any WIN_CERTIFICATE_UEFI_GUID structures. These structures are used in the SetVariable() interface, not GetVariable(), as described in the above examples.*

Status Codes Returned

EFI_SUCCESS	The function completed successfully.
EFI_NOT_FOUND	The variable was not found.
EFI_BUFFER_TOO_SMALL	The *DataSize* is too small for the result. *DataSize* has been updated with the size needed to complete the request. If *Attributes* is not NULL, then the attributes bitmask for the variable has been stored to the memory location pointed-to by *Attributes*.
EFI_INVALID_PARAMETER	*VariableName* is NULL.
EFI_INVALID_PARAMETER	*VendorGuid* is NULL.
EFI_INVALID_PARAMETER	*DataSize* is NULL.
EFI_INVALID_PARAMETER	The *DataSize* is not too small and *Data* is NULL.
EFI_DEVICE_ERROR	The variable could not be retrieved due to a hardware error.
EFI_SECURITY_VIOLATION	The variable could not be retrieved due to an authentication failure.
EFI_UNSUPPORTED	After *ExitBootServices()* has been called, this return code may be returned if no variable storage is supported. The platform should describe this runtime service as unsupported at runtime via an *EFI_RT_PROPERTIES_TABLE* configuration table.

8.2.2 GetNextVariableName()

Summary

Enumerates the current variable names.

Prototype

```
typedef
EFI_STATUS
GetNextVariableName (
  IN OUT UINTN           *VariableNameSize,
  IN OUT CHAR16          *VariableName,
  IN OUT EFI_GUID        *VendorGuid
 );
```

Parameters

VariableNameSize
The size of the *VariableName* buffer. The size must be large enough to fit input string supplied in VariableName buffer.

VariableName
On input, supplies the last *VariableName* that was returned by * GetNextVariableName(). On output, returns the Null-terminated string of the current variable.

VendorGuid
On input, supplies the last *VendorGuid* that was returned by GetNextVariableName(). On output, returns the *VendorGuid* of the current variable. Type EFI_GUID is defined in the *EFI_BOOT_SERVICES.InstallProtocolInterface()* function description.

Description

GetNextVariableName() is called multiple times to retrieve the VariableName and VendorGuid of all variables currently available in the system. On each call to GetNextVariableName() the previous results are passed into the interface, and on output the interface returns the next variable name data. When the entire variable list has been returned, the error EFI_NOT_FOUND is returned.

Note that if EFI_BUFFER_TOO_SMALL is returned, the VariableName buffer was too small for the next variable. When such an error occurs, the VariableNameSize is updated to reflect the size of buffer needed. In all cases when calling GetNextVariableName() the VariableNameSize must not exceed the actual buffer size that was allocated for VariableName. The VariableNameSize must not be smaller the size of the variable name string passed to GetNextVariableName() on input in the *VariableName* buffer.

To start the search, a Null-terminated string is passed in VariableName; that is, *VariableName* is a pointer to a Null character. This is always done on the initial call to GetNextVariableName(). When *VariableName* is a pointer to a Null character, *VendorGuid* is ignored. GetNextVariableName() cannot be used as a filter to return variable names with a specific GUID. Instead, the entire list of variables must be retrieved, and the caller may act as a filter if it chooses. Calls to *SetVariable()* between calls to GetNextVariableName() may produce unpredictable results. If a *VariableName* buffer on input is not a Null-terminated string, EFI_INVALID_PARAMETER is returned. If input values of *VariableName* and *VendorGuid* are not a name and GUID of an existing variable, EFI_INVALID_PARAMETER is returned.

Once *EFI_BOOT_SERVICES.ExitBootServices()* is performed, variables that are only visible during boot services will no longer be returned. To obtain the data contents or attribute for a variable returned by GetNextVariableName(), the *GetVariable()* interface is used.

Status Codes Returned

EFI_SUCCESS	The function completed successfully.
EFI_NOT_FOUND	The next variable was not found.
EFI_BUFFER_TOO_SMALL	The *VariableNameSize* is too small for the result. *VariableNameSize* has been updated with the size needed to complete the request.
EFI_INVALID_PARAMETER	*VariableNameSize* is NULL.
EFI_INVALID_PARAMETER	*VariableName* is NULL.
EFI_INVALID_PARAMETER	*VendorGuid* is NULL.
EFI_INVALID_PARAMETER	The input values of *VariableName* and *VendorGuid* are not a name and GUID of an existing variable.
EFI_INVALID_PARAMETER	Null-terminator is not found in the first *VariableNameSize* bytes of the input *VariableName* buffer.
EFI_DEVICE_ERROR	The variable name could not be retrieved due to a hardware error.
EFI_UNSUPPORTED	After ExitBootServices() has been called, this return code may be returned if no variable storage is supported. The platform should describe this runtime service as unsupported at runtime via an EFI_RT_PROPERTIES_TABLE configuration table.

8.2.3 SetVariable()

Summary

Sets the value of a variable. This service can be used to create a new variable, modify the value of an existing variable, or to delete an existing variable.

Prototype

```
typedef
EFI_STATUS
SetVariable (
  IN CHAR16           *VariableName,
  IN EFI_GUID         *VendorGuid,
  IN UINT32           Attributes,
  IN UINTN            DataSize,
  IN VOID             *Data
);
```

Parameters

VariableName

A Null-terminated string that is the name of the vendor's variable. Each *VariableName* is unique for each *VendorGuid*. *VariableName* must contain 1 or more characters. If *VariableName* is an empty string, then EFI_INVALID_PARAMETER is returned.

VendorGuid

A unique identifier for the vendor. Type EFI_GUID is defined in the *EFI_BOOT_SERVICES.InstallProtocolInterface()* function description.

Attributes

Attributes bitmask to set for the variable. Refer to the *GetVariable()* function description.

DataSize

The size in bytes of the *Data* buffer. Unless the EFI_VARIABLE_APPEND_WRITE, EFI_VARIABLE_AUTHENTICATED_WRITE_ACCESS, EFI_VARIABLE_ENHANCED_AUTHENTICATED_ACCESS, or EFI_VARIABLE_TIME_BASED_AUTHENTICATED_WRITE_ACCESS attribute is set, a size of zero causes the variable to be deleted. When the EFI_VARIABLE_APPEND_WRITE attribute is set, then a

SetVariable() call with a *DataSize* of zero will not cause any change to the variable value (the timestamp associated with the variable may be updated however, even if no new data value is provided;see the description of the EFI_VARIABLE_AUTHENTICATION_2 descriptor below). In this case the DataSize will not be zero since the EFI_VARIABLE_AUTHENTICATION_2 descriptor will be populated).

Data

The contents for the variable.

Related Definitions

```
//*******************************************************
// Variable Attributes
//*******************************************************

// NOTE: This interface is deprecated and should no longer be
used!
//
// EFI_VARIABLE_AUTHENTICATION descriptor
//
// A counter-based authentication method descriptor template
//
typedef struct {
  UINT64                      MonotonicCount;
  WIN_CERTIFICATE_UEFI_GUID   AuthInfo;
} EFI_VARIABLE_AUTHENTICATION;
```

MonotonicCount

Included in the signature of AuthInfo. Used to ensure freshness/no replay. Incremented during each “Write” access.

AuthInfo

Provides the authorization for the variable access. It is a signature across the variable data and the Monotonic Count value. Caller uses Private key that is associated with a public key that has been provisioned via the key exchange.

```
//
// EFI_VARIABLE_AUTHENTICATION_2 descriptor
//
// A time-based authentication method descriptor template
//
typedef struct {
  EFI_TIME                     TimeStamp;
  WIN_CERTIFICATE_UEFI_GUID    AuthInfo;
} EFI_VARIABLE_AUTHENTICATION_2;
```

TimeStamp

Time associated with the authentication descriptor. For the *TimeStamp* value, components *Pad1*, *Nanosecond*, *TimeZone*, *Daylight* and *Pad2* shall be set to 0. This means that the time shall always be expressed in GMT.

AuthInfo

Provides the authorization for the variable access. Only a *CertType* of EFI_CERT_TYPE_PKCS7_GUID is accepted.

```
//
// EFI_VARIABLE_AUTHENTICATION_3 descriptor
//
```

(continues on next page)

(continued from previous page)

```
// An extensible implementation of the Variable Authentication
// structure.
//
#define EFI_VARIABLE_AUTHENTICATION_3_TIMESTAMP_TYPE 1
#define EFI_VARIABLE_AUTHENTICATION_3_NONCE_TYPE 2

typedef struct {
  UINT8 Version;
  UINT8 Type;
  UINT32 MetadataSize;
  UINT32 Flags;
} EFI_VARIABLE_AUTHENTICATION_3;
```

Version

This field is used in case the EFI_VARIABLE_AUTHENTICATION_3 structure itself ever requires updating. For now, it is hardcoded to “0x1”.

Type

Declares what structure immediately follows this structure in the Variable Data payload. For EFI_VARIABLE_AUTHENTICATION_3_TIMESTAMP_TYPE, it will be an instance of EFI_TIME (for the TimeStamp). For EFI_VARIABLE_AUTHENTICATION_3_NONCE_TYPE the structure will be an instance of EFI_VARIABLE_AUTHENTICATION_3_NONCE. This structure is defined below. Note that none of these structures contains a WIN_CERTIFICATE_UEFI_GUID structure. See *Using the EFI_VARIABLE_AUTHENTICATION_3 descriptor* for an explanation of structure sequencing.

MetadataSize

Declares the size of all variable authentication metadata (data related to the authentication of the variable that is not variable data itself), including this header structure, and type-specific structures (eg. EFI_VARIABLE_AUTHENTICATION_3_NONCE), and any WIN_CERTIFICATE_UEFI_GUID structures.

Flags

Bitfield indicating any optional configuration for this call. Currently, the only defined value is: #define EFI_VARIABLE_ENHANCED_AUTH_FLAG_UPDATE_CERT 0x00000001 The presence of this flag on SetVariable() indicates that there are two instances of the WIN_CERTIFICATE_UEFI_GUID structure following the type-specific structures. The first instance describes the new cert to be set as the authority for the variable. The second is the signed data to authorize the current updated.

NOTE: All other bits are currently Reserved on SetVariable().

NOTE: All flags are reserved on GetVariable().

```
//
// EFI_VARIABLE_AUTHENTICATION_3_NONCE descriptor
//
// A nonce-based authentication method descriptor template. This
// structure will always be followed by a
// WIN_CERTIFICATE_UEFI_GUID structure.
```

(continues on next page)

(continued from previous page)

```
//
typedef struct {
  UINT32 NonceSize;
  // UINT8 Nonce[NonceSize];
}  EFI_VARIABLE_AUTHENTICATION_3_NONCE;
```

NonceSize
Indicates the size of the Nonce buffer that follows this field in the structure. Must not be 0.

Nonce (Not a formal structure member)
Unique, random value that guarantees a signed payload cannot be shared between multiple machines or machine families. On SetVariable(), if the Nonce field is all 0's, the host machine will try to use an internally generated random number. Will return *EFI_UNSUPPORTED* if not possible. Also, on SetVariable() if the variable already exists and the nonce is identical to the current nonce, will return EFI_INVALID_PARAMETER.

Description

Variables are stored by the firmware and may maintain their values across power cycles. Each vendor may create and manage its own variables without the risk of name conflicts by using a unique *VendorGuid*.

Each variable has Attributes that define how the firmware stores and maintains the data value. If the EFI_VARIABLE_NON_VOLATILE attribute is not set, the firmware stores the variable in normal memory and it is not maintained across a power cycle. Such variables are used to pass information from one component to another. An example of this is the firmware's language code support variable. It is created at firmware initialization time for access by EFI components that may need the information, but does not need to be backed up to nonvolatile storage.

EFI_VARIABLE_NON_VOLATILE variables are stored in fixed hardware that has a limited storage capacity; sometimes a severely limited capacity. Software should only use a nonvolatile variable when absolutely necessary. In addition, if software uses a nonvolatile variable it should use a variable that is only accessible at boot services time if possible.

A variable must contain one or more bytes of Data. Unless the EFI_VARIABLE_APPEND_WRITE, EFI_VARIABLE_TIME_BASED_AUTHENTICATED_WRITE_ACCESS, or EFI_VARIABLE_ENHANCED_AUTHENTICATED_A attribute is set (see below), using SetVariable() with a DataSize of zero will cause the entire variable to be deleted. The space consumed by the deleted variable may not be available until the next power cycle.

If a variable with matching name, GUID, and attributes already exists, its value is updated.

The Attributes have the following usage rules:

- If a preexisting variable is rewritten with different attributes, SetVariable() shall not modify the variable and shall return EFI_INVALID_PARAMETER. The only exception to this is when the only attribute differing is EFI_VARIABLE_APPEND_WRITE. In such cases the call's successful outcome or not is determined by the actual value being written. There are two exceptions to this rule:
  - If a preexisting variable is rewritten with no access attributes specified, the variable will be deleted.
  - EFI_VARIABLE_APPEND_WRITE attribute presents a special case. It is acceptable to rewrite the variable with or without EFI_VARIABLE_APPEND_WRITE attribute.
- Setting a data variable with no access attributes causes it to be deleted.
- EFI_VARIABLE_AUTHENTICATED_WRITE_ACCESS is deprecated and should not be used. Platforms should return EFI_UNSUPPORTED if a caller to SetVariable() specifies this attribute.
- Unless the EFI_VARIABLE_APPEND_WRITE, EFI_VARIABLE_TIME_BASED_AUTHENTICATED_WRITE_ACCESS, or EFI_VARIABLE_ENHANCED_AUTHENTICATED_WRITE_ACCESS attribute is set, setting a data variable with zero *DataSize* specified, causes it to be deleted.

- Runtime access to a data variable implies boot service access. Attributes that have EFI_VARIABLE_RUNTIME_ACCESS set must also have EFI_VARIABLE_BOOTSERVICE_ACCESS set. The caller is responsible for following this rule.
- Once *EFI_BOOT_SERVICES.ExitBootServices()* is performed, data variables that did not have EFI_VARIABLE_RUNTIME_ACCESS set are no longer visible to *GetVariable()*.
- Once ExitBootServices() is performed, only variables that have EFI_VARIABLE_RUNTIME_ACCESS and EFI_VARIABLE_NON_VOLATILE set can be set with SetVariable(). Variables that have runtime access but that are not nonvolatile are read-only data variables once ExitBootServices() is performed. When the EFI_VARIABLE_ENHANCED_AUTHENTICATED_ACCESS attribute is set in a SetVariable() call, the authentication shall use the EFI_VARIABLE_AUTHENTICATION_3 descriptor, which will be followed by any descriptors indicated in the Type and Flags fields.
- When the EFI_VARIABLE_TIME_BASED_AUTHENTICATED_WRITE_ACCESS attribute is set in a SetVariable() call, the authentication shall use the EFI_VARIABLE_AUTHENTICATION_2 descriptor.
- If both the EFI_VARIABLE_TIME_BASED_AUTHENTICATED_WRITE_ACCESS and the EFI_VARIABLE_ENHANCED_AUTHENTICATED_ACCESS attribute are set in a SetVariable() call, then the firmware must return EFI_INVALID_PARAMETER.
- If the EFI_VARIABLE_APPEND_WRITE attribute is set in a SetVariable() call, then any existing variable value shall be appended with the value of the *Data* parameter. If the firmware does not support the append operation, then the SetVariable() call shall return EFI_INVALID_PARAMETER.
- If the EFI_VARIABLE_TIME_BASED_AUTHENTICATED_WRITE_ACCESS attribute is set in a SetVariable() call, and firmware does not support signature type of the certificate included in the EFI_VARIABLE_AUTHENTICATION_2 descriptor, then the SetVariable() call shall return EFI_INVALID_PARAMETER. The list of signature types supported by the firmware is defined by the SignatureSupport variable. Signature type of the certificate is defined by its digest and encryption algorithms.
- If the EFI_VARIABLE_HARDWARE_ERROR_RECORD attribute is set, *VariableName* and *VendorGuid* must comply with the rules stated in *Hardware Error Record Variables* and *Appendix P — Hardware Error Record Persistence Usage*. Otherwise, the SetVariable() call shall return EFI_INVALID_PARAMETER.
- *Globally Defined Variables* must be created with the attributes defined in the Table *Global Variables* . If a globally defined variable is created with the wrong attributes, the result is indeterminate and may vary between implementations.
- If using the EFI_VARIABLE_ENHANCED_AUTHETICATED_ACCESS interface to update the cert authority for a given variable, it is valid for the *Data* region of the payload to be empty. This would update the cert without modifying the data itself. If the *Data* region is empty AND no NewCert is specified, the variable will be deleted (assuming all authorizations are verified).
- Secure Boot Policy Variable must be created with the EFI_VARIABLE_TIME_BASED_AUTHENTICATED_WRITE_ACCESS attribute set, and the authentication shall use the EFI_VARIABLE_AUTHENTICATION_2 descriptor. If the appropriate attribute bit is not set, then the firmware shall return EFI_INVALID_PARAMETER.

The only rules the firmware must implement when saving a nonvolatile variable is that it has actually been saved to nonvolatile storage before returning EFI_SUCCESS, and that a partial save is not performed. If power fails during a call to SetVariable() the variable may contain its previous value, or its new value. In addition there is no read, write, or delete security protection.

To delete a variable created with the EFI_VARIABLE_TIME_BASED_AUTHENTICATED_WRITE_ACCESS attribute, *SetVariable* must be used with attributes matching the existing variable and the *DataSize* set to the size of the *AuthInfo* descriptor. The *Data* buffer must contain an instance of the *AuthInfo* descriptor which will be validated according to the steps in the appropriate section above referring to updates of Authenticated variables. An attempt to delete a variable created with the EFI_VARIABLE_TIME_BASED_AUTHENTICATED_WRITE_ACCESS attribute for which the prescribed *AuthInfo* validation fails or when called using *DataSize* of zero will fail with an EFI_SECURITY_VIOLATION status.

To delete a variable created with the EFI_VARIABLE_ENHANCED_AUTHENTICATED_ACCESS attribute, *SetVariable* must be used with attributes matching the existing variable and the *DataSize* set to the size of the entire payload including all descriptors and certificates. The *Data* buffer must contain an instance of the EFI_VARIABLE_AUTHENTICATION_3 descriptor which will indicate how to validate the payload according to the description in *Using the EFI_VARIABLE_AUTHENTICATION_3 descriptor*. An attempt to delete a variable created with the EFI_VARIABLE_ENHANCED_AUTHENTICATED_ACCESS attribute for which the prescribed validation fails or when called using *DataSize* of zero will fail with an EFI_SECURITY_VIOLATION status.

Status Codes Returned

EFI_SUCCESS	The firmware has successfully stored the variable and its data as defined by the Attributes.
EFI_INVALID_PARAMETER	An invalid combination of attribute bits, name, and GUID was supplied, or the *DataSize* exceeds the maximum allowed.
EFI_INVALID_PARAMETER	*VariableName* is an empty string.
EFI_OUT_OF_RESOURCES	Not enough storage is available to hold the variable and its data.
EFI_DEVICE_ERROR	The variable could not be saved due to a hardware failure.
EFI_WRITE_PROTECTED	The variable in question is read-only.
EFI_WRITE_PROTECTED	The variable in question cannot be deleted.
EFI_SECURITY_VIOLATION	The variable could not be written due to EFI_VARIABLE_ENHANCED_AUTHENTICATED_ACCESS or EFI_VARI ABLE_TIME_BASED_AUTHENTICATED_WRITE_ACESS being set, but the payload does NOT pass the validation check carried out by the firmware.
EFI_NOT_FOUND	The variable trying to be updated or deleted was not found.
EFI_UNSUPPORTED	This call is not supported by this platform at the time the call is made. The platform should describe this runtime service as unsupported at runtime via an EFI_RT_PROPERTIES_TABLE configuration table.

8.2.4 QueryVariableInfo()

Summary

Returns information about the EFI variables.

Prototype

```
typedef
EFI_STATUS
QueryVariableInfo (
   IN UINT32             Attributes,
   OUT UINT64            *MaximumVariableStorageSize,
   OUT UINT64            *RemainingVariableStorageSize,
   OUT UINT64            *MaximumVariableSize
  );
```

Attributes

Attributes bitmask to specify the type of variables on which to return information. Refer to the *GetVariable()* function description. The EFI_VARIABLE_APPEND_WRITE attribute, if set in the attributes bitmask, will be ignored.

MaximumVariableStorageSize
On output the maximum size of the storage space available for the EFI variables associated with the attributes specified.

RemainingVariableStorageSize
Returns the remaining size of the storage space available for EFI variables associated with the attributes specified.

MaximumVariableSize
Returns the maximum size of an individual EFI variable associated with the attributes specified.

Description

The QueryVariableInfo() function allows a caller to obtain the information about the maximum size of the storage space available for the EFI variables, the remaining size of the storage space available for the EFI variables and the maximum size of each individual EFI variable, associated with the attributes specified.

The *MaximumVariableSize* value will reflect the overhead associated with the saving of a single EFI variable with the exception of the overhead associated with the length of the string name of the EFI variable.

The returned *MaximumVariableStorageSize*, *RemainingVariableStorageSize*, *MaximumVariableSize* information may change immediately after the call based on other runtime activities including asynchronous error events. Also, these values associated with different attributes are not additive in nature.

After the system has transitioned into runtime (after ExitBootServices() is called), an implementation may not be able to accurately return information about the Boot Services variable store. In such cases, EFI_INVALID_PARAMETER should be returned.

Status Codes Returned

EFI_SUCCESS	Valid answer returned.
EFI_INVALID_PARAMETER	An invalid combination of attribute bits was supplied
EFI_UNSUPPORTED	The attribute is not supported on this platform, and the *MaximumVariableStorageSize*, *RemainingVariableStorageSize*, *MaximumVariableSize* are undefined.

8.2.5 Using the EFI_VARIABLE_AUTHENTICATION_3 descriptor

When the attribute EFI_VARIABLE_ENHANCED_AUTHENTICATED_ACCESS is set, the payload buffer (passed into SetVariable() as "Data") shall be constructed as follows:

// NOTE: "||" indicates concatenation.
// NOTE: "[ ]" indicates an optional element.

// Example: EFI_VARIABLE_AUTHENTICATION_3_TIMESTAMP_TYPE
EFI_VARIABLE_AUTHENTICATION_3 || EFI_TIME || [NewCert] || SigningCert || Data

// Example: EFI_VARIABLE_AUTHENTICATION_3_NONCE_TYPE FI_VARIABLE_AUTHENTICATION_3 ||
EFI_VARIABLE_AUTHENTICATION_3_NONCE || [NewCert] || SigningCert || Data

In this example, NewCert and SigningCert are both instances of WIN_CERTIFICATE_UEFI_GUID. The presence of NewCert is indicated by the EFI_VARIABLE_AUTHENTICATION_3.Flags field (see Definition in SetVariable()). If provided – and assuming the payload passes all integrity and security verifications — this cert will be set as the new authority for the underlying variable, even if the variable is being newly created.

The NewCert element must have a CertType of EFI_CERT_TYPE_PKCS7_GUID, and the CertData must be a DER-encoded SignedData structure per PKCS#7 version 1.5 (RFC 2315), which shall be supported both with and without a DER-encoded ContentInfo structure per PKCS#7 version 1.5. When creating the SignedData structure, the following steps shall be followed:

1. Create a WIN_CERTIFICATE_UEFI_GUID structure where CertType is set to EFI_CERT_TYPE_PKCS7_GUID.
2. Use the x509 cert being added as the new authority to sign its own tbsCertificate data.
3. Construct a DER-encoded PKCS #7 version 1.5 SignedData (see [RFC2315]) with the signed content as follows:

   a - SignedData.version shall be set to 1.

   b - SignedData.digestAlgorithms shall contain the digest algorithm used when preparing the signature. Only a digest algorithm of SHA-256 is accepted.

   c - SignedData.contentInfo.contentType shall be set to id-data.

   d - SignedData.contentInfo.content shall be the tbsCertificate data that was signed for the new x509 cert.

   e - SignedData.certificates shall contain, at a minimum, the signer's DER-encoded X.509 certificate.

   f - SignedData.crls is optional.

   g - SignedData.signerInfos shall be constructed as:

   - SignerInfo.version shall be set to 1.
   - SignerInfo.issuerAndSerial shall be present and as in the signer's certificate.
   - SignerInfo.authenticatedAttributes shall not be present.
   - SignerInfo.digestEncryptionAlgorithm shall be set to the algorithm used to sign the data. Only a digest encryption algorithm of RSA with PKCS #1 v1.5 padding (RSASSA_PKCS1v1_5). is accepted.
   - SignerInfo.encryptedDigest shall be present.
   - SignerInfo.unauthenticatedAttributes shall not be present.

4. Set the CertData field to the DER-encoded PKCS#7 SignedData value.

A caller to SetVariable() attempting to create, update, or delete a variable with the EFI_VARIABLE_ENHANCED_AUTHENTICATED_ACCESS set shall perform the following steps to create the SignedData structure for SigningCert:

1. Create an EFI_VARIABLE_AUTHENTICATION_3 Primary Descriptor with the following values:

   a - Version shall be set appropriate to theversion of metadata headers being used (currently 1).

   b - Type should be set based on caller specifications (see EFI_VARIABLE_AUTHENTICATION_3 *descriptor* under SetVariable()).

   c - MetadataSize can be ignored for now, and will be updated when constructing the final payload.

   d - Flags shall be set based on caller specifications.

2. A Secondary Descriptor may need to be created based on the Type.

   a - For EFI_VARIABLE_AUTHENTICATION_3_TIMESTAMP_TYPE type,this will be an instance of EFI_TIME set to thecurrent time.

b - For EFI_VARIABLE_AUTHENTICATION_3_NONCE_TYPE type, this will be an instance of EFI_VARIABLE_AUTHENTICATION_3_NONCE updated with NonceSize set based on caller specifications (must not be zero), and Nonce (informal structure member) set to:

- All zeros to request that the platform create a random nonce.
- Caller specified value for a pre-generated nonce.

3. Hash a serialization of the payload. Serialization shall contain the following elements in this order:

   a - VariableName, VendorGuid, Attributes, and theSecondary Descriptor if it exists for this Type.

   b - Variable's new value (ie. the Data parameter's new variable content).

   c - If this is an update to or deletion of a variable with type EFI_VARIABLE_AUTHENTICATION_3_NONCE, serialize the current nonce. The current nonce is the one currently associated with this variable, not the one in the Secondary Descriptor. Serialize only the nonce buffer contents, not the size or any additional data. If this is an attempt to create a new variable (ie. there is no current nonce), skip this step.

   d - If the authority cert for this variable is being updated and the EFI_VARIABLE_AUTHENTICATION_3.Flags field indicates the presence of a NewCert structure, serialize the entire NewCert structure (described at the beginning of this section).

4. Sign the resulting digest.
5. Create a WIN_CERTIFICATE_UEFI_GUID structure where CertType is set to EFI_CERT_TYPE_PKCS7_GUID.
6. Construct a DER-encoded PKCS #7 version 1.5 SignedData (see [RFC2315]) following the steps described for NewCert (step 3), above, with the following exception:

   a - SignedData.contentInfo.content shall beabsent (the content is provided in the Data parameterto the SetVariable() call)

7. Construct the final payload for SetVariable() according to the descriptions for "payload buffer" at the beginning of this section.
8. Update the EFI_VARIABLE_AUTHENTICATION_3.MetadataSize field to include all parts of the final payload except "Data".

Firmware that implements the SetVariable() services and supports the EFI_VARIABLE_ENHANCED_AUTHENTICATED_ACCESS attribute shall do the following in response to being called:

1. Read the EFI_VARIABLE_AUTHENTICATION_3 descriptor to determine what type of authentication isbeing performed and how to parse the rest of the payload.
2. Verify that SigningCert.CertType EFI_CERT_TYPE_PKCS7_GUID.

   a - If EFI_VARIABLE_AUTHENTICATION_3.Flags field indicates presence of a NewCert, verify thatNewCert.CertType is EFI_CERT_TYPE_PKCS7_GUID.

   b - If either fails, return EFI_INVALID_PARAMETER.

3. If the variable already exists, verify that the incoming type matches the existing type.
4. Verify that any *EFI_TIME* structures have Pad1, Nanosecond, TimeZone, Daylight, and Pad2 fields set to zero.
5. If EFI_VARIABLE_AUTHENTICATION_3_NONCE_TYPE:

   a - Verify that NonceSize is greater than zero.If zero, return EFI_INVALID_PARAMETER.

   b - If incoming nonce is all zeros, confirm that platform supports generating random nonce. If unsupported, return EFI_UNSUPPORTED.

   c - If nonce is specified and variable already exists, verify that incoming nonce does not match existing nonce. If identical, return EFI_INVALID_PARAMETER.

6. If EFI_VARIABLE_AUTHENTICATION_3_TIMESTAMP_TYPE and variable already exists, verify that new timestamp is chronologically greater than current timestamp.
7. Verify the payload signature by:

   a - Parsing entire payload according to descriptors.

   b - Using descriptor contents (and, if necessary, metadata from existing variable) to construct the serialization described previously in this section (step 3 of the SetVariable() instructions).

   c - Compute the digest and compare with the result of applying the SigningCert's public key to the signature.
8. If the variable already exists, verify that the SigningCert authority is the same as the authority already associated with the variable.
9. If NewCert is provided, verify the NewCert signature by:

   a - Parsing entire payload according todescriptors.

   b - Compute a digest of the tbsCertificate of x509 certificate in NewCert and compare with the result of applying NewCert's public key to the signature.

   c - If this fails, return EFI_SECURITY_VIOLATION.

8.2.6 Using the EFI_VARIABLE_AUTHENTICATION_2 descriptor

When the attribute EFI_VARIABLE_TIME_BASED_AUTHENTICATED_WRITE_ACCESS is set, then the Data buffer shall begin with an instance of a complete (and serialized).

EFI_VARIABLE_AUTHENTICATION_2 descriptor. The descriptor shall be followed by the new variable value and DataSize shall reflect the combined size of the descriptor and the new variable value. The authentication descriptor is not part of the variable data and is not returned by subsequent calls to GetVariable().

A caller that invokes the SetVariable() service with the EFI_VARIABLE_TIME_BASED_AUTHENTICATED_WRITE_ACCESS attribute set shall do the following prior to invoking the service:

1. Create a descriptor

   Create an EFI_VARIABLE_AUTHENTICATION_2 descriptor where:

   • TimeStamp is set to the current time.

   NOTE: *In certain environments a reliable time source may not be available. In this case, an implementation may still add values to an authenticated variable since the EFI_VARIABLE_APPEND_WRITE attribute, when set, disables timestamp verification (see below). In these instances, the special time value where every component of the EFI_TIME struct including the Day and Month is set to 0 shall be used.*

   • AuthInfo.CertType is set to EFI_CERT_TYPE_PKCS7_GUID.

2. Hash the serialization of the values of the VariableName, VendorGuid and Attributes parameters of the SetVariable() call and the TimeStamp component of the EFI_VARIABLE_AUTHENTICATION_2 descriptor followed by the variable's new value (i.e. the Data parameter's new variable content). That is, digest = hash (VariableName, VendorGuid, Attributes, TimeStamp, DataNew_variable_content). The NULL character terminating the VariableName value shall not be included in the hash computation.
3. Sign the resulting digest using a selected signature scheme (e.g. PKCS #1 v1.5)

4. Construct a DER-encoded SignedData structure per PKCS#7 version 1.5 (RFC 2315), which shall be supported both with and without a DER-encoded ContentInfo structure per PKCS#7 version 1.5, with the signed content as follows:

   a - SignedData.version shall be set to 1

   b - SignedData.digestAlgorithms shall contain the digest algorithm used when preparing the signature. Only a digest algorithm of SHA-256 is accepted.

   c - SignedData.contentInfo.contentType shall be set to id-data

   d - SignedData.contentInfo.content shall be absent (the content is provided in the Data parameter to the SetVariable() call)

   e - SignedData.certificates shall contain, at a minimum, the signer's DER-encoded X.509 certificate.

   f - SignedData.crls is optional.

   g - SignedData.signerInfos shall be constructed as:

   - SignerInfo.version shall be set to 1
   - SignerInfo.issuerAndSerial shall be present and as in the signer's certificate — SignerInfo.authenticatedAttributes shall not be present.
   - SignerInfo.digestEncryptionAlgorithm shall be set to the algorithm used to sign the data. Only a digest encryption algorithm of RSA with PKCS #1 v1.5 padding (RSASSA_PKCS1v1_5). is accepted.
   - SiginerInfo.encryptedDigest shall be present
   - SignerInfo.unauthenticatedAttributes shall not be present.

5. Set AuthInfo.CertData to the DER-encoded PKCS #7 SignedData value.

6. Construct Data parameter: Construct the SetVariable()'s Data parameter by concatenating the complete, serialized EFI_VARIABLE_AUTHENTICATION_2 descriptor with the new value of the variable (DataNew_variable_content).

Firmware that implements the SetVariable() service and supports the EFI_VARIABLE_TIME_BASED_AUTHENTICATED_WRITE_A
attribute shall do the following in response to being called:

1. Verify that the correct AuthInfo.CertType (EFI_CERT_TYPE_PKCS7_GUID) has been used and that theAuthInfo.CertData value parses correctly as a PKCS #7SignedData value

2. Verify that Pad1, Nanosecond, TimeZone, Daylight and Pad2 components of the TimeStamp value are set to zero. Unless the EFI_VARIABLE_APPEND_WRITE attribute is set, verify that the TimeStamp value is later than the current timestamp value associated with the variable.

3. If the variable SetupMode==1, and the variable is a secure boot policy variable, then the firmware implementation shall consider the checks in the following steps 4 and 5 to have passed, and proceed with updating the variable value as outlined below.

4. Verify the signature by:

   - extracting the EFI_VARIABLE_AUTHENTICATION_2 descriptor from the Data buffer;
   - using the descriptor contents and other parameters to (a) construct the input to the digest algorithm; (b) computing the digest; and (c) comparing the digest with the result of applying the signer's public key to the signature.

5. If the variable is the global PK variable or the global KEK variable, verify that the signature has been made with the current Platform Key.

- If the variable is the “db”, “dbt”, “dbr”, or “dbx” variable mentioned in step 3, verify that the signer’s certificate chains to a certificate in the Key Exchange Key database (or that the signature was made with the current Platform Key).
- If the variable is the “OsRecoveryOrder” or “OsRecovery####” variable mentioned in step 3, verify that the signer’s certificate chains to a certificate in the “dbr” database or the Key Exchange Key database, or that the signature was made with the current Platform Key.
- Otherwise, if the variable is none of the above, it shall be designated a Private Authenticated Variable. If the Private Authenticated Variable does not exist, then the CN of the signing certificate’s Subject and the hash of the tbsCertificate of the top-level issuer certificate (or the signing certificate itself if no other certificates are present or the certificate chain is of length 1) in SignedData.certificates is registered for use in subsequent verifications of this variable. Implementations may store just a single hash of these two elements to reduce storage requirements. If the Private Authenticated variable previously existed, that the signer’s certificate chains to the information previously associated with the variable. Observe that because no revocation list exists for them, if any member of the certificate chain is compromised, the only method to revoke trust in a certificate for a Private Authenticated Variable is to delete the variable, re-issue all certificate authorities in the chain, and re-create the variable using the new certificate chain. As such, the remaining benefits may be strong identification of the originator, or compliance with some certificate authority policy. Further note that the PKCS7 bundle for the authenticated variable update must contain the signing certificate chain, through and including the full certificate of the desired trust anchor. The trust anchor might be a mid-level certificate or root, though many roots may be unsuitable trust anchors due to the number of CAs they issue for different purposes. Some tools require non-default parameters to include the trust anchor certificate.

The driver shall update the value of the variable only if all of these checks pass. If any of the checks fails, firmware must return EFI_SECURITY_VIOLATION.

The firmware shall perform an append to an existing variable value only if the EFI_VARIABLE_APPEND_WRITE attribute is set.

For variables with the GUID EFI_IMAGE_SECURITY_DATABASE_GUID (i.e. where the data buffer is formatted as EFI_SIGNATURE_LIST), the driver shall not perform an append of EFI_SIGNATURE_DATA values that are already part of the existing variable value.

NOTE: *This situation is not considered an error, and shall in itself not cause a status code other than EFI_SUCCESS to be returned or the timestamp associated with the variable not to be updated.*

The firmware shall associate the new timestamp with the updated value (in the case when the EFI_VARIABLE_APPEND_WRITE attribute is set, this only applies if the new TimeStamp value is later than the current timestamp associated with the variable).

If the variable did not previously exist, and is not one of the variables listed in step 3 above, then firmware shall associate the signer’s public key with the variable for future verification purposes.

8.2.7 Using the EFI_VARIABLE_AUTHENTICATION descriptor

NOTE: *This interface is deprecated and should no longer be used! It will be removed from future versions of the spec.*

When the attribute EFI_VARIABLE_AUTHENTICATED_WRITE_ACCESS is set, but the EFI_VARIABLE_TIME_BASED_AUTHENTICATED_WRITE_ACCESS is not set (i.e. when the EFI_VARIABLE_AUTHENTICATION descriptor s used), then the* *Data* buffer shall begin with an instance of the authentication descriptor *AuthInfo* prior to the data payload and *DataSize* should reflect the data and descriptor size. The authentication descriptor is not part of the variable data and is not returned by the subsequent calls to *GetVariable*. The caller shall digest the Monotonic Count value and the associated data for the variable update using the SHA-256 1-way hash algorithm. The ensuing the 32-byte digest will be signed using the private key associated w/ the public 2048-bit RSA key *PublicKey* described in the EFI_CERT_BLOCK_RSA_2048_SHA256 structure.

The WIN_CERTIFICATE shall be used to describe the signature of the variable *Data. In addition, the signature will also include the MonotonicCount value to guard against replay attacks. The MonotonicCount value must be increased by the caller prior to an update of the *Data* when the EFI_VARIABLE_AUTHENTICATED_WRITE_ACCESS is set.

From the EFI_CERT_BLOCK_RSA_2048_SHA256, the *HashType* will be EFI_SHA256_HASH* and the ANY-SIZE_ARRAY of *Signature* will be 256.The WIN_CERTIFICATE_PKCS1_15 could have been used but was not for the following reason: There are possibly various different principals to create authenticated variables, so the public key corresponding to a given principal is added to the *EFI_CERT_BLOCK_RSA_2048_SHA256* within the WIN_CERTIFICATE. This does not lend cryptographic value so much as it provides something akin to a handle for the platform firmware to use during its verification operation.

The *MonotonicCount* value must be strictly greater for each successive variable update operation. This allows for ensuring freshness of the update operation and defense against replay attacks (i.e., if someone had the value of a former *AuthInfo*, such as a Man-in-the-Middle they could not re-invoke that same update session). For maintenance, the party who initially provisioned the variable (i.e., caller of SetVariable) and set the monotonic count will have to pass the credential (key-pair and monotonic count) to any party who is delegated to make successive updates to the variable with the EFI_VARIABLE_AUTHENTICATED_WRITE_ACCESS set. This 3-tuple of {public key, private key, monotonic count} becomes part of the management metadata for these access-controlled items.

The responsibility of the caller that invokes the SetVariable() service with the EFI_VARIABLE_AUTHENTICATED_WRITE_ACCESS attribute will do the following prior to invoking the service:

- Update the Monotonic Count value.
- Hash the variable contents (Data, Size, Monotonic count) using the *HashType* in the *AuthInfo* structure.
- Sign the resultant hash of above step using a caller private key and create the digital signature *Signature*. Ensure that the public key associated with signing private key is in the *AuthInfo* structure.
- Invoke SetVariables with *EFI_VARIABLE_AUTHENTICATED_WRITE_ACCESS* attribute set.

The responsibility of the firmware that implements the SetVariable() service and supports the EFI_VARIABLE_AUTHENTICATED_WRITE_ACCESS attribute will do the following in response to being called:

- The first time it uses SetVariable with the EFI_VARIABLE_AUTHENTICATED_WRITE_ACCESS attribute set. Use the public key in the *AuthInfo* structure for subsequent verification.
- Hash the variable contents (Data, Size, Monotonic count) using the *HashType* in the *AuthInfo* structure.
- Compare the public key in the *AuthInfo* structure with the public key passed in on the first invocation.
- Verify the digital signature *Signature* of the signed hash using the stored public key associated with the variable.
- Compare the verification of the signature with the instance generated by the caller
- If comparison fails, return EFI_SECURITY_VIOLATION.
- Compare the new monotonic count and ensure that it is greater than the last SetVariable operation with the EFI_VARIABLE_AUTHENTICATED_WRITE_ACCESS attribute set.
- If new monotonic count is not strictly greater, then return EFI_SECURITY_VIOLATION.

NOTE: *Special processing by SetVariable() for Secure Boot variables and the Platform Key is defined in Firmware/OS Key Exchange: Creating Trust Relationships*.

8.2.8 Hardware Error Record Persistence

This section defines how Hardware Error Record Persistence is to be implemented. By implementing support for Hardware Error Record Persistence, the platform enables the OS to utilize the EFI Variable Services to save hardware error records so they are persistent and remain available across OS sessions until they are explicitly cleared or overwritten by their creator.

8.2.8.1 Hardware Error Record Non-Volatile Store

A platform which implements support hardware error record persistence is required to guarantee some amount of NVR is available to the OS for saving hardware error records. The platform communicates the amount of space allocated for error records via the QueryVariableInfo routine as described in Appendix P.

8.2.8.2 Hardware Error Record Variables

This section defines a set of Hardware Error Record variables that have architecturally defined meanings. In addition to the defined data content, each such variable has an architecturally defined attribute that indicates when the data variable may be accessed. The variables with an attribute of HR are stored in the portion of NVR allocated for error records. NV, BS and RT have the meanings defined in section 3.2. All hardware error record variables use the EFI_HARDWARE_ERROR_VARIABLE VendorGuid:

```
#define EFI_HARDWARE_ERROR_VARIABLE\
{0x414E6BDD,0xE47B,0x47cc,{0xB2,0x44,0xBB,0x61,0x02,0x0C,0xF5,0x16}}
```

Table 8.8: Hardware Error Record Persistence Variables

Variable Name	Attribute	Description
HwErrRec####	NV, BS, RT, HR	A hardware error record. #### is a printed hex value. No 0x or h is included in the hex value

The HwErrRec#### variable contains a hardware error record. Each HwErrRec#### variable is the name "HwErrRec" appended with a unique 4-digit hexadecimal number. For example, HwErrRec0001, HwErrRec0002, HwErrRecF31A, etc. The HR attribute indicates that this variable is to be stored in the portion of NVR allocated for error records.

8.2.8.3 Common Platform Error Record Format

Error record variables persisted using this interface are encoded in the Common Platform Error Record format, which is described in appendix N of the *UEFI Specification*. Because error records persisted using this interface conform to this standardized format, the error information may be used by entities other than the OS.

8.3 Time Services

This section contains function definitions for time-related functions that are typically needed by operating systems at runtime to access underlying hardware that manages time information and services. The purpose of these interfaces is to provide operating system writers with an abstraction for hardware time devices, thereby relieving the need to access legacy hardware devices directly. There is also a stalling function for use in the preboot environment. *Time Services Functions* lists the time services functions described in this section:

Table 8.9: Time Services Functions

Name	Type	Description
GetTime	Runtime	Returns the current time and date, and the time-keeping capabilities of the platform.
SetTime	Runtime	Sets the current local time and date information.
GetWakeupTime	Runtime	Returns the current wakeup alarm clock setting.
SetWakeupTime	Runtime	Sets the system wakeup alarm clock time

8.3.1 GetTime()

Summary

Returns the current time and date information, and the time-keeping capabilities of the hardware platform.

Prototype

```
typedef
EFI_STATUS
GetTime (
   OUT EFI_TIME                  *Time,
   OUT EFI_TIME_CAPABILITIES     *Capabilities OPTIONAL
  );
```

Parameters

Time
A pointer to storage to receive a snapshot of the current time. Type EFI_TIME is defined in “Related Definitions.”

Capabilities
An optional pointer to a buffer to receive the real time clock device’s capabilities. Type EFI_TIME_CAPABILITIES is defined in “Related Definitions.”

Related Definitions

```
//*************************************************
//EFI_TIME
//*************************************************
// This represents the current time information
typedef struct {
   UINT16    Year;              // 1900 - 9999
   UINT8     Month;             // 1 - 12
   UINT8     Day;               // 1 - 31
   UINT8     Hour;              // 0 - 23
   UINT8     Minute;            // 0 - 59
   UINT8     Second;            // 0 - 59
   UINT8     Pad1;
   UINT32    Nanosecond;        // 0 - 999,999,999
   INT16     TimeZone;          // -1440 to 1440 or 2047
   UINT8     Daylight;
   UINT8     Pad2;
 }   EFI_TIME;

//***************************************************
// Bit Definitions for EFI_TIME.Daylight. See below.
```

(continues on next page)

(continued from previous page)

```
//*******************************************************
#define EFI_TIME_ADJUST_DAYLIGHT   0x01
#define EFI_TIME_IN_DAYLIGHT       0x02

//*******************************************************
// Value Definition for EFI_TIME.TimeZone. See below.
//*******************************************************
#define EFI_UNSPECIFIED_TIMEZONE   0x07FF
```

Year, Month, Day

The current local date.

Hour, Minute, Second, Nanosecond

The current local time. Nanoseconds report the current fraction of a second in the device. The format of the time is *hh:mm:ss.nnnnnnnnn*. A battery backed real time clock device maintains the date and time.

TimeZone

The time's offset in minutes from UTC. If the value is EFI_UNSPECIFIED_TIMEZONE, then the time is interpreted as a local time. The *TimeZone* is the number of minutes that the local time is relative to UTC. To calculate the *TimeZone* value, follow this equation: Localtime = UTC - *TimeZone*.

To further illustrate this, an example is given below:

PST (Pacific Standard Time is 12PM) = UTC (8PM) - 8 hours (480 minutes)

In this case, the value for *Timezone* would be 480 if referencing PST.

Daylight

A bitmask containing the daylight savings time information for the time.

The EFI_TIME_ADJUST_DAYLIGHT bit indicates if the time is affected by daylight savings time or not. This value does not indicate that the time has been adjusted for daylight savings time. It indicates only that it should be adjusted when the EFI_TIME enters daylight savings time.

If EFI_TIME_IN_DAYLIGHT is set, the time has been adjusted for daylight savings time.

All other bits must be zero.

When entering daylight saving time, if the time is affected, but hasn't been adjusted (DST = 1), use the new calculation:

1. The date/time should be increased by the appropriate amount.
2. The *TimeZone* should be decreased by the appropriate amount (EX: +480 changes to +420 when moving from PST to PDT).
3. The *Daylight* value changes to 3.

When exiting daylight saving time, if the time is affected and has been adjusted (DST = 3), use the new calculation:

1. The date/time should be decreased by the appropriate amount.
2. The *TimeZone* should be increased by the appropriate amount.
3. The *Daylight* value changes to 1.

```
//*******************************************************
// EFI_TIME_CAPABILITIES
//*******************************************************
// This provides the capabilities of the
// real time clock device as exposed through the EFI
```

(continues on next page)

(continued from previous page)

```
interfaces.
typedef struct {
   UINT32                  Resolution;
   UINT32                  Accuracy;
   BOOLEAN                 SetsToZero;
}   EFI_TIME_CAPABILITIES;
```

Resolution
Provides the reporting resolution of the real-time clock device in counts per second. For a normal PC-AT CMOS RTC device, this value would be 1 Hz, or 1, to indicate that the device only reports the time to the resolution of 1 second.

Accuracy
Provides the timekeeping accuracy of the real-time clock in an error rate of 1E-6 parts per million. For a clock with an accuracy of 50 parts per million, the value in this field would be 50,000,000.

SetsToZero
A **TRUE** indicates that a time set operation clears the device's time below the Resolution reporting level. A **FALSE** indicates that the state below the Resolution level of the device is not cleared when the time is set. Normal PC-AT CMOS RTC devices set this value to **FALSE**.

Description

The GetTime() function returns a time that was valid sometime during the call to the function. While the returned EFI_TIME structure contains TimeZone and Daylight savings time information, the actual clock does not maintain these values. The current time zone and daylight saving time information returned by GetTime() are the values that were last set via *SetTime()*.

The GetTime() function should take approximately the same amount of time to read the time each time it is called. All reported device capabilities are to be rounded up.

During runtime, if a PC-AT CMOS device is present in the platform the caller must synchronize access to the device before calling GetTime().

Status Codes Returned

EFI_SUCCESS	The operation completed successfully.
EFI_INVALID_PARAMETER	*Time* is NULL.
EFI_DEVICE_ERROR	The time could not be retrieved due to a hardware error.
EFI_UNSUPPORTED	This call is not supported by this platform at the time the call is made. The platform should describe this runtime service as unsupported at runtime via an *EFI_RT_PROPERTIES_TABLE* configuration table.

8.3.2 SetTime()

Summary

Sets the current local time and date information.

Prototype

```
typedef
EFI_STATUS
SetTime (
```

(continues on next page)

(continued from previous page)

```
  IN EFI_TIME       *Time
 );
```

Parameters

Time

A pointer to the current time. Type EFI_TIME is defined in the *GetTime()* function description. Full error checking is performed on the different fields of the EFI_TIME structure (refer to the EFI_TIME definition in the GetTime() function description for full details), and EFI_INVALID_PARAMETER is returned if any field is out of range.

Description

The SetTime() function sets the real time clock device to the supplied time, and records the current time zone and daylight savings time information. The SetTime() function is not allowed to loop based on the current time. For example, if the device does not support a hardware reset for the sub-resolution time, the code is not to implement the feature by waiting for the time to wrap.

During runtime, if a PC-AT CMOS device is present in the platform the caller must synchronize access to the device before calling SetTime().

Status Codes Returned

EFI_SUCCESS	The operation completed successfully.
EFI_INVALID_PARAMETER	A time field is out of range.
EFI_DEVICE_ERROR	The time could not be set due to a hardware error.
EFI_UNSUPPORTED	This call is not supported by this platform at the time the call is made. The platform should describe this runtime service as unsupported at runtime via an *EFI_RT_PROPERTIES_TABLE* configuration table.

8.3.3 GetWakeupTime()

Summary

Returns the current wakeup alarm clock setting.

Prototype

```
typedef
EFI_STATUS
GetWakeupTime (
   OUT BOOLEAN            *Enabled,
   OUT BOOLEAN            *Pending,
   OUT EFI_TIME           *Time
  );
```

Parameters

Enabled

Indicates if the alarm is currently enabled or disabled.

Pending

Indicates if the alarm signal is pending and requires acknowledgement.

Time

The current alarm setting. Type *EFI_TIME* is defined in the *GetTime()* function description.

Description

The alarm clock time may be rounded from the set alarm clock time to be within the resolution of the alarm clock device. The resolution of the alarm clock device is defined to be one second.

During runtime, if a PC-AT CMOS device is present in the platform the caller must synchronize access to the device before calling GetWakeupTime().

Status Codes Returned

EFI_SUCCESS	The alarm settings were returned.
EFI_INVALID_PARAMETER	*Enabled* is NULL.
EFI_INVALID_PARAMETER	*Pending* is NULL.
EFI_INVALID_PARAMETER	*Time* is NULL.
EFI_DEVICE_ERROR	The wakeup time could not be retrieved due to a hardware error.
EFI_UNSUPPORTED	This call is not supported by this platform at the time the call is made. The platform should describe this runtime service as unsupported at runtime via an *EFI_RT_PROPERTIES_TABLE* configuration table.

8.3.4 SetWakeupTime()

Summary

Sets the system wakeup alarm clock time.

Prototype

```
typedef
EFI_STATUS
SetWakeupTime (
   IN BOOLEAN         Enable,
   IN EFI_TIME        *Time OPTIONAL
  );
```

Parameters

Enable

Enable or disable the wakeup alarm.

Time

If Enable is **TRUE**, the time to set the wakeup alarm for. Type EFI_TIME is defined in the *GetTime()* function description. If Enable is **FALSE**, then this parameter is optional, and may be NULL.

Description

Setting a system wakeup alarm causes the system to wake up or power on at the set time. When the alarm fires, the alarm signal is latched until it is acknowledged by calling SetWakeupTime() to disable the alarm. If the alarm fires before the system is put into a sleeping or off state, since the alarm signal is latched the system will immediately wake up. If the alarm fires while the system is off and there is insufficient power to power on the system, the system is powered on when power is restored.

For an ACPI-aware operating system, this function only handles programming the wakeup alarm for the desired wakeup time. The operating system still controls the wakeup event as it normally would through the ACPI Power Management register set.

The resolution for the wakeup alarm is defined to be 1 second.

During runtime, if a PC-AT CMOS device is present in the platform the caller must synchronize access to the device before calling SetWakeupTime().

Status Codes Returned

EFI_SUCCESS	If *Enable* is **TRUE**, then the wakeup alarm was enabled. If *Enable* is **FALSE**, then the wakeup alarm was disabled.
EFI_INVALID_PARAMETER	A time field is out of range.
EFI_DEVICE_ERROR	The wakeup time could not be set due to a hardware error.
EFI_UNSUPPORTED	This call is not supported by this platform at the time the call is made. The platform should describe this runtime service as unsupported at runtime via an *EFI_RT_PROPERTIES_TABLE* configuration table.

8.4 Virtual Memory Services

This section contains function definitions for the virtual memory support that may be optionally used by an operating system at runtime. If an operating system chooses to make EFI runtime service calls in a virtual addressing mode instead of the flat physical mode, then the operating system must use the services in this section to switch the EFI runtime services from flat physical addressing to virtual addressing. *Virtual Memory Functions* lists the virtual memory service functions described in this section. The system firmware must follow the processor-specific rules outlined in *IA-32 Platforms* through *AArch64 Platforms* in the layout of the EFI memory map to enable the OS to make the required virtual mappings.

Table 8.14: Virtual Memory Functions

Name	**Type**	**Description**
SetVirtualAddressMap	Runtime	Used by an OS loader to convert from physical addressing to virtual addressing.
ConvertPointer	Runtime	Used by EFI components to convert internal pointers when switching to virtual addressing.

8.4.1 SetVirtualAddressMap()

Summary

Changes the runtime addressing mode of EFI firmware from physical to virtual.

Prototype

```
typedef
EFI_STATUS
SetVirtualAddressMap (
   IN UINTN                 MemoryMapSize,
   IN UINTN                 DescriptorSize,
   IN UINT32                DescriptorVersion,
   IN EFI_MEMORY_DESCRIPTOR *VirtualMap
  );
```

Parameters

MemoryMapSize
The size in bytes of *VirtualMap*.

DescriptorSize
The size in bytes of an entry in the VirtualMap.

DescriptorVersion
The version of the structure entries in VirtualMap.

VirtualMap
An array of memory descriptors which contain new virtual address mapping information for all runtime ranges. Type EFI_MEMORY_DESCRIPTOR is defined in the *EFI_BOOT_SERVICES.GetMemoryMap()* function description.

Description

The SetVirtualAddressMap() function is used by the OS loader. The function can only be called at runtime, and is called by the owner of the system's memory map: i.e., the component which called *EFI_BOOT_SERVICES.ExitBootServices()*. All events of type EVT_SIGNAL_VIRTUAL_ADDRESS_CHANGE must be signaled before SetVirtualAddressMap() returns.

This call changes the addresses of the runtime components of the EFI firmware to the new virtual addresses supplied in the VirtualMap. The supplied VirtualMap must provide a new virtual address for every entry in the memory map at ExitBootServices() that is marked as being needed for runtime usage. All of the virtual address fields in the VirtualMap must be aligned on 4 KiB boundaries.

The call to SetVirtualAddressMap() must be done with the physical mappings. On successful return from this function, the system must then make any future calls with the newly assigned virtual mappings. All address space mappings must be done in accordance to the cacheability flags as specified in the original address map.

When this function is called, all events that were registered to be signaled on an address map change are notified. Each component that is notified must update any internal pointers for their new addresses. This can be done with the *ConvertPointer()* function. Once all events have been notified, the EFI firmware reapplies image "fix-up" information to virtually relocate all runtime images to their new addresses. In addition, all of the fields of the EFI Runtime Services Table except SetVirtualAddressMap and ConvertPointer must be converted from physical pointers to virtual pointers using the ConvertPointer() service. The SetVirtualAddressMap() and ConvertPointer() services are only callable in physical mode, so they do not need to be converted from physical pointers to virtual pointers. Several fields of the EFI System Table must be converted from physical pointers to virtual pointers using the ConvertPointer() service. These fields include FirmwareVendor, RuntimeServices, and ConfigurationTable. Because contents of both the EFI Runtime Services Table and the EFI System Table are modified by this service, the 32-bit CRC for the EFI Runtime Services Table and the EFI System Table must be recomputed.

A virtual address map may only be applied one time. Once the runtime system is in virtual mode, calls to this function return EFI_UNSUPPORTED.

Status Codes Returned

EFI_SUCCESS	The virtual address map has been applied.
EFI_UNSUPPORTED	EFI firmware is not at runtime, or the EFI firmware is already in virtual address mapped mode.
EFI_INVALID_PARAMETER	*DescriptorSize* or *DescriptorVersion* is invalid.
EFI_NO_MAPPING	A virtual address was not supplied for a range in the memory map that requires a mapping.
EFI_NOT_FOUND	A virtual address was supplied for an address that is not found in the memory map.
EFI_UNSUPPORTED	This call is not supported by this platform at the time the call is made. The platform should describe this runtime service as unsupported at runtime via an *EFI_RT_PROPERTIES_TABLE* configuration table.

8.4.2 ConvertPointer()

Summary

Determines the new virtual address that is to be used on subsequent memory accesses.

Prototype

```
typedef
EFI_STATUS
ConvertPointer (
   IN UINTN             DebugDisposition,
   IN VOID              **Address
  );
```

Parameters

DebugDisposition
Supplies type information for the pointer being converted. See "Related Definitions."

Address
A pointer to a pointer that is to be fixed to be the value needed for the new virtual address mappings being applied.

Related Definitions

```
//*******************************************************
// EFI_OPTIONAL_PTR
//*******************************************************
#define EFI_OPTIONAL_PTR          0x00000001
```

Description

The ConvertPointer() function is used by an EFI component during the *SetVirtualAddressMap()* operation. ConvertPointer() must be called using physical address pointers during the execution of SetVirtualAddressMap().

The ConvertPointer() function updates the current pointer pointed to by Address to be the proper value for the new address map. Only runtime components need to perform this operation. The *EFI_BOOT_SERVICES.CreateEvent()* function is used to create an event that is to be notified when the address map is changing. All pointers the component has allocated or assigned must be updated.

If the EFI_OPTIONAL_PTR flag is specified, the pointer being converted is allowed to be NULL.

Once all components have been notified of the address map change, firmware fixes any compiled in pointers that are embedded in any runtime image.

Status Codes Returned

EFI_SUCCESS	The pointer pointed to by *Address* was modified.
EFI_NOT_FOUND	The pointer pointed to by *Address* was not found to be part of the current memory map. This is normally fatal.
EFI_INVALID_PARAMETER	*Address* is NULL.
EFI_INVALID_PARAMETER	**Address* is NULL and *DebugDisposition* does not have the *EFI_OPTIONAL_PTR* bit set.

continues on next page

Table 8.16 – continued from previous page

EFI_UNSUPPORTED	This call is not supported by this platform at the time the call is made. The platform should describe this runtime service as unsupported at runtime via an *EFI_RT_PROPERTIES_TABLE* configuration table.

8.5 Miscellaneous Runtime Services

This section contains the remaining function definitions for runtime services not defined elsewhere but which are required to complete the definition of the EFI environment. The Table, below, lists the *Miscellaneous Runtime Services* .

Miscellaneous Runtime Services

Table 8.17: Miscellaneous Runtime Services

Name	Type	Description
GetNextHigh-Monotonic-Count	Runtime	Returns the next high 32 bits of the platform's monotonic counter.
ResetSystem	Runtime	Resets the entire platform.
UpdateCapsule	Runtime	Pass capsules to the firmware. The firmware may process the capsules immediately or return a value to be passed into *Reset System* that will cause the capsule to be processed by the firmware as part of the reset process.
QueryCapsule-Capabilities	Runtime	Returns if the capsule can be supported via UpdateCapsule()

8.5.1 Reset System

This section describes the reset system runtime service and its associated data structures.

8.5.1.1 ResetSystem()

Summary

Resets the entire platform. If the platform supports See *ref:EFI_RESET_NOTIFICATION_PROTOCOL*, then prior to completing the reset of the platform, all of the pending notifications must be called.

Prototype

```
typedef
VOID
(EFIAPI \*EFI_RESET_SYSTEM) (
   IN EFI_RESET_TYPE           ResetType,
   IN EFI_STATUS               ResetStatus,
   IN UINTN                    DataSize,
   IN VOID                     *ResetData OPTIONAL
 );
```

Parameters

ResetType

The type of reset to perform. Type EFI_RESET_TYPE is defined in "Related Definitions" below.

ResetStatus

The status code for the reset. If the system reset is part of a normal operation, the status code would be EFI_SUCCESS. If the system reset is due to some type of failure the most appropriate EFI Status code would be used.

DataSize

The size, in bytes, of *ResetData*.

ResetData

For a ResetType of EfiResetCold, EfiResetWarm, or EfiResetShutdown the data buffer starts with a Null-terminated string, optionally followed by additional binary data. The string is a description that the caller may use to further indicate the reason for the system reset. For a ResetType of EfiResetPlatformSpecific the data buffer also starts with a Null-terminated string that is followed by an EFI_GUID that describes the specific type of reset to perform.

Related Definitions

```
//*******************************************************
// EFI_RESET_TYPE
//*******************************************************
typedef enum {
   EfiResetCold,
   EfiResetWarm,
   EfiResetShutdown
   EfiResetPlatformSpecific
}   EFI_RESET_TYPE;
```

Description

The ResetSystem() function resets the entire platform, including all processors and devices, and reboots the system.

Calling this interface with *ResetType* of EfiResetCold causes a system-wide reset. This sets all circuitry within the system to its initial state. This type of reset is asynchronous to system operation and operates without regard to cycle boundaries. EfiResetCold is tantamount to a system power cycle.

Calling this interface with *ResetType* of EfiResetWarm causes a system-wide initialization. The processors are set to their initial state, and pending cycles are not corrupted. If the system does not support this reset type, then an EfiResetCold must be performed.

Calling this interface with *ResetType* of EfiResetShutdown causes the system to enter a power state equivalent to the ACPI G2/S5 or G3 states. If the system does not support this reset type, then when the system is rebooted, it should exhibit the EfiResetCold attributes.

Calling this interface with *ResetType* of EfiResetPlatformSpecific causes a system-wide reset. The exact type of the reset is defined by the EFI_GUID that follows the Null-terminated Unicode string passed into *ResetData*. If the platform does not recognize the EFI_GUID in *ResetData* the platform must pick a supported reset type to perform.The platform may optionally log the parameters from any non-normal reset that occurs.

The ResetSystem() function does not return.

8.5.2 Get Next High Monotonic Count

This section describes the GetNextHighMonotonicCount runtime service and its associated data structures.

8.5.2.1 GetNextHighMonotonicCount()

Summary

Returns the next high 32 bits of the platform's monotonic counter.

Prototype

```
typedef
EFI_STATUS
GetNextHighMonotonicCount (
  OUT UINT32               *HighCount
 );
```

Parameters

HighCount
Pointer to returned value.

Description

The GetNextHighMonotonicCount() function returns the next high 32 bits of the platform's monotonic counter.

The platform's monotonic counter is comprised of two 32-bit quantities: the high 32 bits and the low 32 bits. During boot service time the low 32-bit value is volatile: it is reset to zero on every system reset and is increased by 1 on every call to GetNextMonotonicCount(). The high 32-bit value is nonvolatile and is increased by 1 whenever the system resets, whenever GetNextHighMonotonicCount() is called, or whenever the low 32-bit count (returned by GetNextMonoticCount()) overflows.

The *EFI_BOOT_SERVICES.GetNextMonotonicCount()* function is only available at boot services time. If the operating system wishes to extend the platform monotonic counter to runtime, it may do so by utilizing GetNextHighMonotonicCount(). To do this, before calling *EFI_BOOT_SERVICES.ExitBootServices()* the operating system would call GetNextMonotonicCount() to obtain the current platform monotonic count. The operating system would then provide an interface that returns the next count by:

- Adding 1 to the last count.
- Before the lower 32 bits of the count overflows, call GetNextHighMonotonicCount(). This will increase the high 32 bits of the platform's nonvolatile portion of the monotonic count by 1.

This function may only be called at Runtime.

Status Codes Returned

EFI_SUCCESS	The next high monotonic count was returned.
EFI_DEVICE_ERROR	The device is not functioning properly.
EFI_INVALID_PARAMETER	*HighCount* is NULL.
EFI_UNSUPPORTED	This call is not supported by this platform at the time the call is made. The platform should describe this runtime service as unsupported at runtime via an *EFI_RT_PROPERTIES_TABLE* configuration table.

8.5.3 Update Capsule

This runtime function allows a caller to pass information to the firmware. Update Capsule is commonly used to update the firmware FLASH or for an operating system to have information persist across a system reset.

8.5.3.1 UpdateCapsule()

Summary

Passes capsules to the firmware with both virtual and physical mapping. Depending on the intended consumption, the firmware may process the capsule immediately. If the payload should persist across a system reset, the reset value returned from *EFI_QueryCapsuleCapabilities* must be passed into *Reset System* and will cause the capsule to be processed by the firmware as part of the reset process.

Prototype

```
typedef
EFI_STATUS
UpdateCapsule (
   IN EFI_CAPSULE_HEADER      **CapsuleHeaderArray,
   IN UINTN                   CapsuleCount,
   IN EFI_PHYSICAL_ADDRESS    ScatterGatherList OPTIONAL
  );
```

Parameters

CapsuleHeaderArray
Virtual pointer to an array of virtual pointers to the capsules being passed into update capsule. Each capsules is assumed to stored in contiguous virtual memory. The capsules in the *CapsuleHeaderArray* must be the same capsules as the *ScatterGatherList*. The *CapsuleHeaderArray* must have the capsules in the same order as the *ScatterGatherList*.

CapsuleCount
Number of pointers to EFI_CAPSULE_HEADER in *CapsuleHeaderArray*.

ScatterGatherList
Physical pointer to a set of EFI_CAPSULE_BLOCK_DESCRIPTOR that describes the location in physical memory of a set of capsules. See "Related Definitions" for an explanation of how more than one capsule is passed via this interface. The capsules in the *ScatterGatherList* must be in the same order as the *CapsuleHeaderArray*. This parameter is only referenced if the capsules are defined to persist across system reset.

Related Definitions

```
typedef struct {
UINT64                         Length;
union {
   EFI_PHYSICAL_ADDRESS          DataBlock;
   EFI_PHYSICAL_ADDRESS          ContinuationPointer;
 }Union;
} EFI_CAPSULE_BLOCK_DESCRIPTOR;
```

Length
Length in bytes of the data pointed to by *DataBlock/ContinuationPointer*.

DataBlock
Physical address of the data block. This member of the union is used if *Length* is not equal to zero.

ContinuationPointer
Physical address of another block of EFI_CAPSULE_BLOCK_DESCRIPTOR structures. This member of the union is used if Length is equal to zero. If ContinuationPointer is zero this entry represents the end of the list.

This data structure defines the *ScatterGatherList* list the OS passes to the firmware. *ScatterGatherList* represents an array of structures and is terminated with a structure member whose *Length* is 0 and *DataBlock* physical address is 0. If Length is 0 and *DataBlock* physical address is not 0, the specified physical address is known as a “continuation pointer” and it points to a further list of EFI_CAPSULE_BLOCK_DESCRIPTOR structures. A continuation pointer is used to allow the scatter gather list to be contained in physical memory that is not contiguous. It also is used to allow more than a single capsule to be passed at one time.

```
typedef struct {
   EFI_GUID             CapsuleGuid;
   UINT32               HeaderSize;
   UINT32               Flags;
   UINT32               CapsuleImageSize;
 } EFI_CAPSULE_HEADER;
```

CapsuleGuid
A GUID that defines the contents of a capsule.

HeaderSize
The size of the capsule header. This may be larger than the size of the EFI_CAPSULE_HEADER since *CapsuleGuid* may imply extended header entries.

Flags
The Flags[15:0] bits are defined by CapsuleGuid. Flags[31:16] are defined by this specification.

CapsuleImageSize
Size in bytes of the capsule (including capsule header).

```
#define CAPSULE_FLAGS_PERSIST_ACROSS_RESET 0x00010000
#define CAPSULE_FLAGS_POPULATE_SYSTEM_TABLE 0x00020000
#define CAPSULE_FLAGS_INITIATE_RESET 0x00040000
```

NOTE: *A capsule which has the* CAPSULE_FLAGS_INITIATE_RESET Flag *must have* CAPSULE_FLAGS_PERSIST_ACROSS_RESET *set in its header as well. Firmware that encounters a capsule which has the* CAPSULE_FLAGS_INITIATE_RESET Flag *set in its header will initiate a reset of the platform which is compatible with the passed-in capsule request and will not return back to the caller.*

```
typedef struct {
   UINT32                  CapsuleArrayNumber;
   VOID*                   CapsulePtr[1];
 } EFI_CAPSULE_TABLE;
```

CapsuleArrayNumber
The number of entries in the array of capsules.

CapsulePtr
A pointer to an array of capsules that contain the same CapsuleGuid value. Each CapsulePtr points to an instance of an EFI_CAPSULE_HEADER, with the capsule data concatenated on its end.

Description

The UpdateCapsule() function allows the operating system to pass information to firmware. The UpdateCapsule() function supports passing capsules in operating system virtual memory back to firmware. Each capsule is contained in a contiguous virtual memory range in the operating system, but both a virtual and physical mapping for the capsules are passed to the firmware.

If a capsule has the CAPSULE_FLAGS_PERSIST_ACROSS_RESET Flag set in its header, the firmware will process the capsules after system reset. The caller must ensure to reset the system using the required reset value obtained from QueryCapsuleCapabilities. If this flag is not set, the firmware will process the capsules immediately.

A capsule which has the CAPSULE_FLAGS_POPULATE_SYSTEM_TABLE *Flag* must have CAPSULE_FLAGS_PERSIST_ACROSS_RESET set in its header as well. Firmware that processes a capsule that has the CAPSULE_FLAGS_POPULATE_SYSTEM_TABLE Flag set in its header will coalesce the contents of the capsule from the ScatterGatherList into a contiguous buffer and must then place a pointer to this coalesced capsule in the EFI System Table after the system has been reset. Agents searching for this capsule will look in the EFI_CONFIGURATION_TABLE and search for the capsule's GUID and associated pointer to retrieve the data after the reset.

Flag Firmware Behavior

Table 8.19: Flag Firmware Behavior

Flags	Firmware Behavior
No Specification defined flags	Firmware attempts to immediately processes or launch the capsule. If capsule is not recognized, can expect an error.
CAPSULE_FLAGS_PERSIST_ACROSS_RESET	Firmware will attempt to process or launch the capsule across a reset. If capsule is not recognized, can expect an error. If the processing requires a reset which is unsupported by the platform, expect an error.
CAPSULE_FLAGS_PERSIST_ACROSS_RESET + CAPSULE_FLAGS_POPULATE_SYSTEM_TABLE	Firmware will coalesce the capsule from the ScatterGatherList into a contiguous buffer and place a pointer to the coalesced capsule in the EFI System Table. Platform recognition of the capsule type is not required. If the action requires a reset which is unsupported by the platform, expect an error.
CAPSULE_FLAGS_PERSIST_ACROSS_RESET + CAPSULE_FLAGS_INITIATE_RESET	Firmware will attempt to process or launch the capsule across a reset. The firmware will initiate a reset which is compatible with the passed-in capsule request and will not return back to the caller. If the capsule is not recognized, can expect an error. If the processing requires a reset which is unsupported by the platform, expect an error.
CAPSULE_FLAGS_PERSIST_ACROSS_RESET + CAPSULE_FLAGS_INITIATE_RESET + CAPSULE_FLAGS_POPULATE_SYSTEM_TABLE	The firmware will initiate a reset which is compatible with the passed-in capsule request and not return back to the caller. Upon resetting, the firmware will coalesce the capsule from the ScatterGatherList into a contiguous buffer and place a pointer to the coalesced capsule in the EFI System Table. Platform recognition of the capsule type is not required. If the action requires a reset which is unsupported by the platform, expect an error.

The EFI System Table entry must use the GUID from the CapsuleGuid field of the EFI_CAPSULE_HEADER. The EFI System Table entry must point to an array of capsules that contain the same CapsuleGuid value. The array must be prefixed by a UINT32 that represents the size of the array of capsules.

The set of capsules is pointed to by ScatterGatherList and CapsuleHeaderArray so the firmware will know both the physical and virtual addresses of the operating system allocated buffers. The scatter-gather list supports the situation where the virtual address range of a capsule is contiguous, but the physical addresses are not.

On architectures where the processor's view of main memory is incoherent with the caches when the memory management unit is disabled, callers to *UpdateCapsule()* must perform cache maintenance to main memory on each ScatterGatherList element before calling *UpdateCapsule()*. This requirement only applies after the OS has called *ExitBootServices()*.

If any of the capsules that are passed into this function encounter an error, the entire set of capsules will not be processed and the error encountered will be returned to the caller.

Status Codes Returned

EFI_SUCCESS	Valid capsule was passed. If CAPSULE_FLAGS_PERSIST_ACROSS_RESET is not set, the capsule has been successfully processed by the firmware.
EFI_INVALID_PARAMETER	*CapsuleSize*, or an incompatible set of flags were set in the capsule header.
EFI_INVALID_PARAMETER	*CapsuleCount* is 0
EFI_DEVICE_ERROR	The capsule update was started, but failed due to a device error.
EFI_UNSUPPORTED	The capsule type is not supported on this platform.
EFI_OUT_OF_RESOURCES	When ExitBootServices() has been previously called this error indicates the capsule is compatible with this platform but is not capable of being submitted or processed in runtime. The caller may resubmit the capsule prior to ExitBootServices().
EFI_OUT_OF_RESOURCES	When ExitBootServices() has not been previously called then this error indicates the capsule is compatible with this platform but there are insufficient resources to process.
EFI_UNSUPPORTED	This call is not supported by this platform at the time the call is made. The platform should describe this runtime service as unsupported at runtime via an EFI_RT_PROPERTIES_TABLE configuration table.

8.5.3.2 Capsule Definition

A capsule is simply a contiguous set of data that starts with an EFI_CAPSULE_HEADER. The *CapsuleGuid* field in the header defines the format of the capsule.

The capsule contents are designed to be communicated from an OS-present environment to the system firmware. To allow capsules to persist across system reset, a level of indirection is required for the description of a capsule, since the OS primarily uses virtual memory and the firmware at boot time uses physical memory. This level of abstraction is accomplished via the EFI_CAPSULE_BLOCK_DESCRIPTOR. The EFI_CAPSULE_BLOCK_DESCRIPTOR allows the OS to allocatecontiguous virtual address space and describe this address space to the firmware as a discontinuous set of physical address ranges. The firmware is passed both physical and virtual addresses and pointers to describe the capsule so the firmware can process the capsule immediately or defer processing of the capsule until after a system reset.

In most instruction sets and OS architecture, allocation of physical memory is possible only on a “page” granularity (which can range for 4 KiB to at least 1 MiB). The EFI_CAPSULE_BLOCK_DESCRIPTOR must have the following properties to ensure the safe and well defined transition of the data:

- Each new capsule must start on a new page of memory.
- All pages except for the last must be completely filled by the capsule.

  – It is legal to pad the header to make it consume an entire page of data to enable the passing of page aligned data structures via a capsule. The last page must have at least one byte of capsule in it.
- Pages must be naturally aligned
- Pages may not overlap on another
- Firmware may never make an assumption about the page sizes the operating system is using.

Multiple capsules can be concatenated together and passed via a single call to UpdateCapsule().The physical address description of capsules are concatenated by converting the terminating EFI_CAPSULE_BLOCK_DESCRIPTOR entry of the 1st capsule into a continuation pointer by making it point to the EFI_CAPSULE_BLOCK_DESCRIPTOR that represents the start of the 2nd capsule. There is only a single terminating EFI_CAPSULE_BLOCK_DESCRIPTOR entry and it is at the end of the last capsule in the chain.

The following algorithm must be used to find multiple capsules in a single scatter gather list:

- Look at the capsule header to determine the size of the capsule
  - The first Capsule header is always pointed to by the first EFI_CAPSULE_BLOCK_DESCRIPTOR entry
- Walk the EFI_CAPSULE_BLOCK_DESCRIPTOR list keeping a running count of the size each entry represents.
- If the EFI_CAPSULE_BLOCK_DESCRIPTOR entry is a continuation pointer and the running current capsule size count is greater than or equal to the size of the current capsule this is the start of the next capsule.
- Make the new capsules the current capsule and repeat the algorithm.

  Figure, below, shows a Scatter-Gather list of EFI_CAPSULE_BLOCK_DESCRIPTOR structures that describes two capsules. The left side of the figure shows OS view of the capsules as two separate contiguous virtual memory buffers. The center of the figure shows the layout of the data in system memory. The right hand side of the figure shows the ScatterGatherList list passed into the firmware. Since there are two capsules two independent EFI_CAPSULE_BLOCK_DESCRIPTOR lists exist that were joined together via a continuation pointer in the first list.

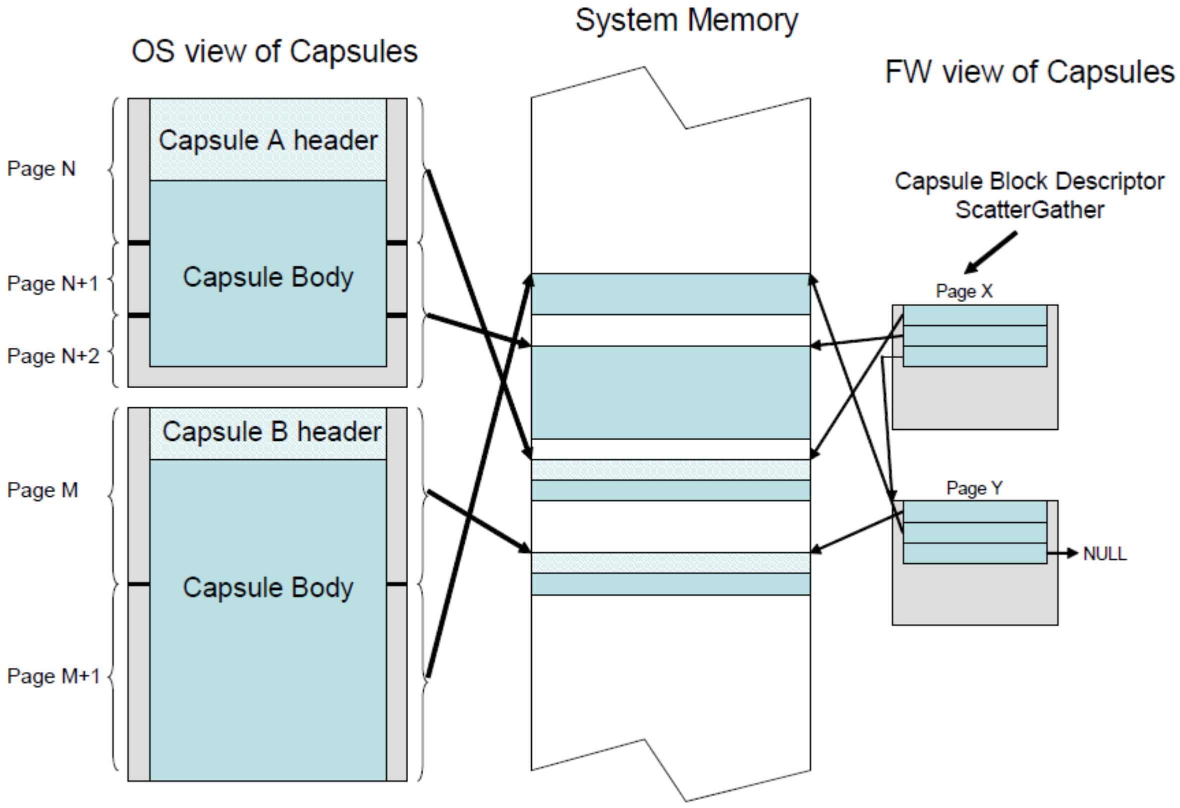

Fig. 8.1: Scatter-Gather List of EFI_CAPSULE_BLOCK_DESCRIPTOR Structures

8.5.3.3 EFI_MEMORY_RANGE_CAPSULE_GUID

This capsule structure definition provides a means by which a third-party component (e.g. OS) can describe to firmware regions in memory should be left untouched across the next reset.

Support for this capsule is optional. For platforms that support this capsule, they must advertise EFI_MEMORY_RANGE_CAPSULE in the EFI Configuration table using the EFI_MEMORY_RANGE_CAPSULE_GUID as the GUID in the GUID/pointer pair.

```
// {0DE9F0EC-88B6-428F-977A-258F1D0E5E72}
#define EFI_MEMORY_RANGE_CAPSULE_GUID \
   { 0xde9f0ec, 0x88b6, 0x428f, \
    { 0x97, 0x7a, 0x25, 0x8f, 0x1d, 0xe, 0x5e, 0x72 } }
```

A memory range descriptor.

```
typedef struct
   EFI_PHYSICAL_ADDRESS          Address;
   UINT64                        Length;
} EFI_MEMORY_RANGE;
```

Address

Physical address of memory location being described.

Length

Length in bytes.

The capsule descriptor that describes the memory ranges a platform firmware should leave untouched.

```
typedef struct {
   EFI_CAPSULE_HEADER            Header;
   UINT32                        OsRequestedMemoryType;
   UINT64                        NumberOfMemoryRanges;
   EFI_MEMORY_RANGE              MemoryRanges[];
 } EFI_MEMORY_RANGE_CAPSULE;
```

Header

Header.CapsuleGuid = EFI_MEMORY_RANGE_CAPSULE_GUID

Header.Flags = CAPSULE_FLAGS_PERSIST_ACROSS_RESET

OsRequestedMemoryType

Must be in the 0x80000000-0xFFFFFFFF range

When UEFI Firmware processes the capsule, contents described in MemoryRanges[] will show up as OsRequestedMemoryType values in the EFI Memory Map.

NumberofMemoryRanges

Number of MemoryRanges[] entries. Must be a value of 1 or greater.

MemoryRanges[]

An array of memory ranges. Equivalent to MemoryRanges[NumberOfMemoryRanges].

For a platform that intends to support the EFI_MEMORY_RANGE_CAPSULE, it must advertise EFI_MEMORY_RANGE_CAPSULE_RESULT in the EFI Configuration table using the EFI_MEMORY_RANGE_CAPSULE_GUID as the GUID in the GUID/pointer pair.

```
typedef struct {
   UINT64              FirmwareMemoryRequirement;
   UINT64              NumberOfMemoryRanges;
} EFI_MEMORY_RANGE_CAPSULE_RESULT
```

FirmwareMemoryRequirement
The maximum amount of memory in bytes that the UEFI firmware requires to initialize.

NumberofMemoryRanges
Will be 0 if no EFI_MEMORY_RANGE_CAPSULE has been processed. If a EFI_MEMORY_RANGE_CAPSULE was processed, this number will be identical to the EFI_MEMORY_RANGE_CAPSULE.NumberOfMemoryRanges value.

8.5.3.4 QueryCapsuleCapabilities()

Summary

Returns if the capsule can be supported via UpdateCapsule().

Prototype

```
typedef
EFI_STATUS
QueryCapsuleCapabilities (
   IN EFI_CAPSULE_HEADER         **CapsuleHeaderArray,
   IN UINTN                      CapsuleCount,
   OUT UINT64                    *MaximumCapsuleSize,
   OUT EFI_RESET_TYPE            *ResetType
  );
```

CapsuleHeaderArray
Virtual pointer to an array of virtual pointers to the capsules being passed into update capsule. The capsules are assumed to stored in contiguous virtual memory.

CapsuleCount*
Number of pointers to EFI_CAPSULE_HEADER in *CapsuleHeaderArray*.

MaximumCapsuleSize
On output the maximum size in bytes that UpdateCapsule() can support as an argument to UpdateCapsule() via *CapsuleHeaderArray* and ScatterGatherList. Undefined on input.

ResetType
Returns the type of reset required for the capsule update. Undefined on input.

Description

The QueryCapsuleCapabilities() function allows a caller to test to see if a capsule or capsules can be updated via UpdateCapsule(). The Flags values in the capsule header and size of the entire capsule is checked.

If the caller needs to query for generic capsule capability a fake EFI_CAPSULE_HEADER can be constructed where *CapsuleImageSize* is equal to *HeaderSize* that is equal to sizeof (EFI_CAPSULE_HEADER). To determine reset requirements, CAPSULE_FLAGS_PERSIST_ACROSS_RESET should be set in the Flags field of the EFI_CAPSULE_HEADER.

Status Codes Returned

EFI_SUCCESS	Valid answer returned.
EFI_INVALID_PARAMETER	MaximumCapsuleSize is NULL.
EFI_UNSUPPORTED	The capsule type is not supported on this platform, and MaximumCapsuleSize and ResetType are undefined.
EFI_OUT_OF_RESOURCES	When ExitBootServices() has been previously called this error indicates the capsule is compatible with this platform but is not capable of being submitted or processed in runtime. The caller may resubmit the capsule prior to ExitBootServices().
EFI_OUT_OF_RESOURCES	When ExitBootServices() has not been previously called then this error indicates the capsule is compatible with this platform but there are insufficient resources to process.
EFI_UNSUPPORTED	This call is not supported by this platform at the time the call is made. The platform should describe this runtime service as unsupported at runtime via an *EFI_RT_PROPERTIES_TABLE* configuration table.

8.5.4 Exchanging information between the OS and Firmware

The firmware and an Operating System may exchange information through the *OsIndicationsSupported* and the *OSIndications* variables as follows:

- The *OsIndications* variable returns a UINT64 bitmask owned by the OS and is used to indicate which features the OS wants firmware to enable or which actions the OS wants the firmware to take. The OS will supply this data with a SetVariable() call.
- The *OsIndicationsSupported* variable returns a UINT64 bitmask owned by the firmware and indicates which of the OS indication features and actions that the firmware supports. This variable is recreated by firmware every boot, and cannot be modified by the OS.

The EFI_OS_INDICATIONS_BOOT_TO_FW_UI bit can be set in the *OsIndicationsSupported* variable by the firmware, if the firmware supports OS requests to stop at a firmware user interface. The EFI_OS_INDICATIONS_BOOT_TO_FW_UI bit can be set by the OS in the *OsIndications* variable, if the OS desires for the firmware to stop at a firmware user interface on the next boot. Once the firmware consumes this bit in the *OsIndications* variable and stops at the firmware user interface, the firmware should clear the bit from the *OsIndications* variable in order to acknowledge to the OS that the information was consumed and, more importantly, to prevent the firmware user interface from showing again on subsequent boots.

The EFI_OS_INDICATIONS_TIMESTAMP_REVOCATION bit can be set in the *OSIndicationsSupported* variable by the firmware, if the firmware supports timestamp based revocation and the " *dbt* " uthorized timestamp database variable.

The EFI_OS_INDICATIONS_FMP_CAPSULE_SUPPORTED bit is set in *OsIndicationsSupported* variable if platform supports processing of Firmware Management Protocol update capsule as defined in *Dependency Expression Instruction Set*. If set in *OsIndications* variable, the EFI_OS_INDICATIONS_FMP_CAPSULE_SUPPORTED bit has no function and is cleared on the next reboot.

The EFI_OS_INDICATIONS_FILE_CAPSULE_DELIVERY_SUPPORTED bit in *OsIndicationsSupported* variable is set if platform supports processing of file capsules per *Delivery of Capsules via file on Mass Storage Device*.

When submitting capsule via the Mass Storage Device method of *Delivery of Capsules via file on Mass Storage Device*, the bit EFI_OS_INDICATIONS_FILE_CAPSULE_DELIVERY_SUPPORTED in *OsIndications* variable must be set by submitter to trigger processing of submitted capsule on next reboot. This bit will be cleared from *OsIndications* by system firmware in all cases during processing following reboot.

The EFI_OS_INDICATIONS_CAPSULE_RESULT_VAR_SUPPORTED bit is set in *OsIndicationsSupported* variable if platform supports reporting of deferred capsule processing by creation of result variable as defined in *UEFI* *variable reporting on the Success or any Errors encountered in processing of capsules after restart*. This bit has no function if set in *OsIndications*.

The EFI_OS_INDICATIONS_START_OS_RECOVERY bit is set in the *OsIndicationsSupported* variable if the platform supports both the ability for an OS to indicate that OS-defined recovery should commence upon reboot, as well as support for the short-form File Path Media Device Path (See *Load Option Processing*). If this bit is set in *OsIndications*, the platform firmware must bypass processing of the *BootOrder* variable during boot, and skip directly to OS-defined recovery (*OS-Defined Boot Option Recovery*) followed by Platform-defined recovery (*Platform-Defined Boot Option Recovery*). System firmware must clear this bit in *OsIndications* when it starts OS-defined recovery.

The EFI_OS_INDICATIONS_START_PLATFORM_RECOVERY bit is set in the *OsIndicationsSupported* variable if the platform supports both the ability for an OS to indicate that Platform-defined recovery should commence upon reboot, as well as support for the short-form File Path Media Device Path (*Load Option Processing*). If this bit is set in *OsIndications*, the platform firmware must bypass processing of the *BootOrder* variable during boot, and skip directly to *Platform-Defined Boot Option Recovery* . System firmware must clear this bit in *OsIndications* when it starts Platform-defined recovery.

In all cases, if either of EFI_OS_INDICATIONS_START_OS_RECOVERY or EFI_OS_INDICATIONS_START_PLATFORM_RECOVERY is set in *OsIndicationsSupported*, both must be set and supported.

The EFI_OS_INDICATIONS_JSON_CONFIG_DATA_REFRESH bit is set in the *OsIndications* variable by submitter to trigger collecting current configuration and reporting the refreshed data to EFI System Configuration Table on next boot. If not set, platform will not collect current configuration but report the cached configuration data to EFI System Configuration Table. The configuration data shall be installed to EFI System Configuration Table using the format of EFI_JSON_CAPSULE_CONFIG_DATA defined in *Defined JSON Capsule Data Structure*. This bit will be cleared from *OsIndications* by system firmware once the refreshed data is reported.

If set in the *OsIndicationsSupported* variable, the EFI_OS_INDICATIONS_JSON_CONFIG_DATA_REFRESH bit has no function and is cleared on the next reboot.

```

8.5.5 Delivery of Capsules via file on Mass Storage Device

As an alternative to the UpdateCapsule() runtime API, capsules of any type supported by platform may also be delivered to firmware via a file within the EFI system partition on the mass storage device targeted for boot. Capsules staged using this method are processed on the next system restart. This method is only available when booting from mass storage devices which are formatted with GPT and contain an EFI System Partition in the device image. System firmware will search for capsule when EFI_OS_INDICATIONS_FILE_CAPSULE_DELIVERY_SUPPORTED bit in *OsIndications* is set as described in *Exchanging information between the OS and Firmware*.

The directory EFIUpdateCapsule (letter case ignored) within the active EFI System Partition is defined for delivery of capsule to firmware. The binary structure of a capsule file on mass storage device is identical to the contents of capsule delivered via the EFI RunTime API except that fragmentation using EFI_CAPSULE_BLOCK_DESCRIPTOR is not supported and the single capsule must be stored in contiguous bytes within the file starting with EFI_CAPSULE_HEADER. The size of the file must equal EFI_CAPSULE_HEADER. *CapsuleImageSize* or error will be generated and the capsule ignored. Only a single capsule with a single EFI_CAPSULE_HEADER may be submitted within a file but more than one file each containing a capsule may be submitted during a single restart.

The file name of the capsule shall be chosen by submitter using 8-bit ASCII characters appropriate to the file system of the EFI system partition (*System Partition*). After examination and processing of a file placed in this directory the file will (if possible) be deleted by firmware. The deletion is performed in case of successful processing and also in the case of error but failure to successfully delete is not itself a reportable error.

More than one capsule file each containing a single capsule image may be stored in the specified directory. In case of multiple files, the system firmware shall process files in alphabetical order using sort based on CHAR16 numerical value of file name characters, compared left to right. Lower case letter characters will be converted to upper case before compare. When comparing file names of unequal length, the space character shall be used to pad shorter file names. In case of file name containing one or more period characters (.), the right-most period, and the text to the right of the right-most period in the file name, will be removed before compare. In case of any file names with identical text after excluding any text after the right-most period, the order of processing shall be determined by sorting of any text found to right of the right-most period in file name string.

If a capsule processing is terminated by error any remaining additional capsule files will be processed normally.

The directory EFIUpdateCapsule is checked for capsules only within the EFI system partition on the device specified in the active boot option determine by reference to BootNext variable or *BootOrder* variable processing. The active Boot Variable is the variable with highest priority *BootNext* or within *BootOrder* that refers to a device found to be present. Boot variables in *BootOrder* but referring to devices not present are ignored when determining active boot variable.

The device to be checked for EFIUpdateCapsule is identified by reference to *FilePathList* field within the selected active *Boot####* variable. The system firmware is not required to check mass storage devices that do not contain boot target that is highest priority for boot nor to check a second EFI system partition not the target of the active boot variable.

In all cases that a capsule is identified for processing the system is restarted after capsule processing is completed. In case where *BootNext* variable was set, this variable is cleared when capsule processing is performed without actual boot of the variable indicated.

8.5.6 UEFI variable reporting on the Success or any Errors encountered in processing of capsules after restart

In cases where the processing of capsules is (1) delivered by call to UpdateCapsule() API but deferred to next restart, or (2) when capsules are delivered via mass storage device, a UEFI variable is created by firmware to indicate to capsule provider the status of the capsule processing. In the case were multiple capsules are delivered in calls to UpdateCapsule(), or multiple files on disk as described in *Delivery of Capsules via file on Mass Storage Device*, or when a capsule contains multiple payloads as described in *Dependency Expression Instruction Set*, a separate result variable will be created for each capsule payload processed. The firmware will over-write result variables when calculated variable name already exists. However, to avoid unnecessarily consuming system variable store the result variable should be deleted by capsule provider after result status is examined.

UEFI variable reports will not be used when the entirety of capsule processing occurs within the call to UpdateCapsule() function.

The reporting variable attributes will be EFI_VARIABLE_NON_VOLATILE + EFI_VARIABLE_BOOTSERVICE_ACCESS + EFI_VARIABLE_RUNTIME_ACCESS.

The Vendor GUID of the reporting variable will be EFI_CAPSULE_REPORT_GUID. The name of the reporting variable will be *CapsuleNNNN* where *NNNN* is 4-digit hex number chosen by the firmware. The values of *NNNN* will be incremented by firmware starting at *Capsule0000* and continuing up to the platform-defined maximum.

The platform will publish the platform maximum in a read-only variable named EFI_CAPSULE_REPORT_GUID: *CapsuleMax*. The contents of *CapsuleMax* will be the string "CapsuleNNNN" where *NNNN* is the highest value used by platform before rolling over to *Capsule0000*.The platform will also publish the name of the last variable created in EFI_CAPSULE_REPORT_GUID: *CapsuleLast*.

When creating a new result variable, any previous variable with the same name will be overwritten. In case where variable storage is limited system firmware may optionally delete oldest report variables to create free space. If sufficient variable space cannot be freed the variable is not created.

Table 8.22: Variables Using EFI_CAPSULE_REPORT_GUID

Variable Name	**Attributes**	**Internal Format**
Capsule0000, Capsule0001, … up to max	NV, BS, RT	EFI_CAP SULE_RESULT_VARIABLE
CapsuleMax	BS, RT, Read-Only	CHAR16[11] (no zero terminator)
CapsuleLast	NV, BS, RT, Read-Only	CHAR16[11] (no zero terminator)

8.5.6.1 EFI_CAPSULE_REPORT_GUID

```
// {39B68C46-F7FB-441B-B6EC-16B0F69821F3}
#define EFI_CAPSULE_REPORT_GUID \
 { 0x39b68c46, 0xf7fb, 0x441b, \
  {0xb6, 0xec, 0x16, 0xb0, 0xf6, 0x98, 0x21, 0xf3 }};
```

8.5.6.1.1 Structure of the Capsule Processing ResultVariable

The Capsule Processing Result Variable contents always begin with the EFI_CAPSULE_RESULT_VARIABLE_HEADER structure. The value of *CapsuleGuid* determines any additional data that may follow within the instance of the Result Variable contents. For some values of *CapsuleGuid* no additional data may be defined.

As noted below, *VariableTotalSize* is the size of complete result variable including the entire header and any additional data required for particular *CapsuleGuid* types.

```
typedef struct {
   UINT32               VariableTotalSize;
   UINT32               Reserved; //for alignment
   EFI_GUID             CapsuleGuid;
   EFI_TIME             CapsuleProcessed;
   EFI_STATUS           CapsuleStatus;
}  EFI_CAPSULE_RESULT_VARIABLE_HEADER;
```

VariableTotalSize
Size in bytes of the variable including any data beyond header as specified by *CapsuleGuid*.

CapsuleGuid
Guid from EFI_CAPSULE_HEADER

CapsuleProcessed
Timestamp using system time when processing completed.

CapsuleStatus
Result of the capsule processing. Exact interpretation of any error code may depend upon type of capsule processed.

8.5.6.1.2 Additional Structure When CapsuleGuid is EFI_FIRMWARE_MANAGEMENT_CAPSULE_ID_GUID

The capsule Processing Result Variable contents always begin with EFI_CAPSULE_RESULT_VARIABLE_HEADER. When *CapsuleGuid* is EFI_FIRMWARE_MANAGEMENT_CAPSULE_ID_GUID, the header is followed by additional data as defined by EFI_CAPSULE_RESULT_VARIABLE_FMP.

```
typedef struct {
   UINT16              Version;
   UINT8               PayloadIndex;
   UINT8               UpdateImageIndex;

   EFI_GUID            UpdateImageTypeId;
   // CHAR16           CapsuleFileName [];
   // CHAR16           CapsuleTarget [];
}   EFI_CAPSULE_RESULT_VARIABLE_FMP;
```

Version
The version of this structure, currently 0x00000001.

PayloadIndex
The index, starting from zero, of the payload within the FMP capsule which was processed to generate this report.

UpdateImageIndex
The *UpdateImageIndex* from EFI_FIRMWARE_MANAGEMENT_CAPSULE_IMAGE_HEADER (after unsigned conversion from UINT8 to UINT16).

UpdateImageTypeId
The *UpdateImageTypeId* Guid from EFI_FIRMWARE_MANAGEMENT_CAPSULE_IMAGE_HEADER.

CapsuleFileName
In case of capsule loaded from disk, the zero-terminated array containing file name of capsule that was processed. In case of capsule submitted directly to UpdateCapsule() there is no file name, and this field is required to contain a single 16-bit zero character which is included in *VariableTotalSize*.

CapsuleTarget
This field will contain a zero-terminated CHAR16 string containing the text representation of the device path of device publishing Firmware Management Protocol (if present). In case where device path is not present and the target is not otherwise known to firmware, or when payload was blocked by policy, or skipped, this field is required to contain a single 16-bit zero character which is included in *VariableTotalSize*.

8.5.6.1.3 Additional Structure When CapsuleGuid is EFI_JSON_CAPSULE_ID_GUID

The Capsule Processing Result Variable contents always begin with EFI_CAPSULE_RESULT_VARIABLE_HEADER. When CapsuleGuid is EFI_JSON_CAPSULE_ID_GUID, the header is followed by additional data as defined by EFI_CAPSULE_RESULT_VARIABLE_JSON.

```
typedef struct {
   UINT32 Version;
   UINT32 CapsuleId;
   UINT32 RespLength;
   UINT8 Resp[];
 } EFI_CAPSULE_RESULT_VARIABLE_JSON;
```

Version
The version of this structure, currently 0x00000001.

CapsuleId

The unique identifier of the capsule whose processing result is recorded in this variable.

0x00000000 - 0xEFFFFFFF - Implementation Reserved

0xF0000000 - 0xFFFFFFFF - Specification Reserved

#define REDFISH_DEFINED_JSON_SCHEMA 0xF000000

The JSON payload shall conform to a Redfish-defined JSON schema, see DMTF-Redfish Specification.

RespLength
The length of *Resp* in bytes.

Resp
Variable length buffer containing the replied JSON payload to the caller who delivered JSON capsule to system. The definition of the JSON schema used in the replied payload is beyond the scope of this specification.

Table 8.23: Status Codes Returned in CapsuleStatus

EFI_SUCCESS	Valid capsule was passed and the capsule has been successfully processed by the firmware.
EFI_INVALID_PARAMETER	Invalid capsule size, or an incompatible set of flags were set in the capsule header. In the case of a capsule file, the file size was not valid or an error was detected in the internal structure of the file.
EFI_DEVICE_ERROR	The capsule update was started, but failed due to a device error.
EFI_ACCESS_DENIED	Image within capsule was not loaded because the platform policy prohibits the image from being loaded.
EFI_LOAD_ERROR	For capsule with included driver, no driver with correct format for the platform was found.
EFI_UNSUPPORTED	The capsule type is not supported on this platform. Or the capsule internal structures were not recognized as valid by the platform.
EFI_OUT_OF_RESOURCES	There were insufficient resources to process the capsule.
EFI_NOT_READY	Capsule payload blocked by platform policy.
EFI_ABORTED	Capsule payload was skipped.
EFI_UNSUPPORTED	This call is not supported by this platform at the time the call is made. The platform should describe this runtime service as unsupported at runtime via an EFI_RT_PROPERTIES_TABLE configuration table.

CHAPTER
NINE

PROTOCOLS - EFI LOADED IMAGE

This section defines EFI_LOADED_IMAGE_PROTOCOL and the EFI_LOADED_IMAGE_DEVICE_PATH_PROTOCOL. Respectively, these protocols describe an Image that has been loaded into memory and specifies the device path used when a PE/COFF image was loaded through the EFI Boot Service LoadImage(). These descriptions include the source from which the image was loaded, the current location of the image in memory, the type of memory allocated for the image, and the parameters passed to the image when it was invoked.

9.1 EFI Loaded Image Protocol

9.1.1 EFI_LOADED_IMAGE_PROTOCOL

Summary

Can be used on any image handle to obtain information about the loaded image.

GUID

```
#define EFI_LOADED_IMAGE_PROTOCOL_GUID \
  {0x5B1B31A1,0x9562,0x11d2,\
    {0x8E,0x3F,0x00,0xA0,0xC9,0x69,0x72,0x3B}}
```

Revision Number

```
#define EFI_LOADED_IMAGE_PROTOCOL_REVISION 0x1000
```

Protocol Interface Structure

```
typedef struct {
   UINT32                        Revision;
   EFI_HANDLE                    ParentHandle;
   EFI_System_Table              *SystemTable;

   // Source location of the image
   EFI_HANDLE                    DeviceHandle;
   EFI_DEVICE_PATH_PROTOCOL      *FilePath;
   VOID                          *Reserved;

   // Image's load options
   UINT32                        LoadOptionsSize;
   VOID                          *LoadOptions;

```

(continues on next page)

(continued from previous page)

```
   // Location where image was loaded
   VOID                          *ImageBase;
   UINT64                        ImageSize;
   EFI_MEMORY_TYPE               ImageCodeType;
   EFI_MEMORY_TYPE               ImageDataType;
   EFI_IMAGE_UNLOAD              Unload;
} EFI_LOADED_IMAGE_PROTOCOL;
```

Parameters

Revision
Defines the revision of the EFI_LOADED_IMAGE_PROTOCOL structure. All future revisions will be backward compatible to the current revision.

ParentHandle
Parent image's image handle. NULL if the image is loaded directly from the firmware's boot manager. Type EFI_HANDLE is defined in Services – Boot Services.

SystemTable
The image's EFI system table pointer. Type EFI_SYSTEM_TABLE defined in *EFI System Table*.

DeviceHandle
The device handle that the EFI Image was loaded from. Type EFI_HANDLE is defined in Services – Boot Services.

FilePath
A pointer to the file path portion specific to DeviceHandle that the EFI Image was loaded from. EFI_DEVICE_PATH_PROTOCOL is defined in *EFI Device Path Protocol* .

Reserved
Reserved. DO NOT USE.

LoadOptionsSize
The size in bytes of LoadOptions.

LoadOptions
A pointer to the image's binary load options. See the OptionalData parameter in the *Load Options* section of the Boot Manager chapter for information on the source of the LoadOptions data.

ImageBase
The base address at which the image was loaded.

ImageSize
The size in bytes of the loaded image.

ImageCodeType
The memory type that the code sections were loaded as. Type EFI_MEMORY_TYPE is defined in Services – Boot Services.

ImageDataType
The memory type that the data sections were loaded as. Type *EFI_MEMORY_TYPE* is defined in in Services – Boot Services.

Unload
Function that unloads the image - see Section 9.1.2.

Description

Each loaded image has an image handle that supports EFI_LOADED_IMAGE_PROTOCOL. When an image is started, it is passed the image handle for itself. The image can use the handle to obtain its relevant image data stored in the

EFI_LOADED_IMAGE_PROTOCOL structure, such as its load options.

9.1.2 EFI_LOADED_IMAGE_PROTOCOL.Unload()

Summary

Unloads an image from memory.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_IMAGE_UNLOAD) (
  IN EFI_HANDLE               ImageHandle,
  );
```

Parameters

ImageHandle
The handle to the image to unload. Type EFI_HANDLE *Driver Model Boot Services*

Description

The Unload() function is a callback that a driver registers to do cleanup when the UnloadImage boot service function is called.

Status Codes Returned

EFI_SUCCESS	The image was unloaded.
EFI_INVALID_PARAMETER	The *ImageHandle* was not valid.

9.2 EFI Loaded Image Device Path Protocol

9.2.1 EFI_LOADED_IMAGE_DEVICE_PATH_PROTOCOL

Summary

When installed, the Loaded Image Device Path Protocol specifies the device path that was used when a PE/COFF image was loaded through the EFI Boot Service LoadImage().

GUID

```
#define EFI_LOADED_IMAGE_DEVICE_PATH_PROTOCOL_GUID \
   {0xbc62157e,0x3e33,0x4fec,\
  {0x99,0x20,0x2d,0x3b,0x36,0xd7,0x50,0xdf}}
```

Description

The Loaded Image Device Path Protocol uses the same protocol interface structure as the Device Path Protocol defined in Chapter 9. The only difference between the Device Path Protocol and the Loaded Image Device Path Protocol is the protocol GUID value.

The Loaded Image Device Path Protocol must be installed onto the image handle of a PE/COFF image loaded through the EFI Boot Service LoadImage(). A copy of the device path specified by the *DevicePath* parameter to the EFI Boot Service LoadImage() is made before it is installed onto the image handle. It is legal to call LoadImage() for a buffer in memory with a NULL *DevicePath* parameter. In this case, the Loaded Image Device Path Protocol is installed with a NULL interface pointer.

CHAPTER

TEN

PROTOCOLS – DEVICE PATH PROTOCOL

This section contains the definition of the device path protocol and the information needed to construct and manage device paths in the UEFI environment. A device path is constructed and used by the firmware to convey the location of important devices, such as the boot device and console, consistent with the software-visible topology of the system.

10.1 Device Path Overview

A *Device Path* is used to define the programmatic path to a device. The primary purpose of a Device Path is to allow an application, such as an OS loader, to determine the physical device that the interfaces are abstracting.

A collection of device paths is usually referred to as a name space. ACPI, for example, is rooted around a name space that is written in ASL (ACPI Source Language). Given that EFI does not replace ACPI and defers to ACPI when ever possible, it would seem logical to utilize the ACPI name space in EFI. However, the ACPI name space was designed for usage at operating system runtime and does not fit well in platform firmware or OS loaders. Given this, EFI defines its own name space, called a *Device Path*.

A Device Path is designed to make maximum leverage of the ACPI name space. One of the key structures in the Device Path defines the linkage back to the ACPI name space. The Device Path also is used to fill in the gaps where ACPI defers to buses with standard enumeration algorithms. The Device Path is able to relate information about which device is being used on buses with standard enumeration mechanisms. The Device Path is also used to define the location on a medium where a file should be, or where it was loaded from. A special case of the Device Path can also be used to support the optional booting of legacy operating systems from legacy media.

The Device Path was designed so that the OS loader and the operating system could tell which devices the platform firmware was using as boot devices. This allows the operating system to maintain a view of the system that is consistent with the platform firmware. An example of this is a "headless" system that is using a network connection as the boot device and console. In such a case, the firmware will convey to the operating system the network adapter and network protocol information being used as the console and boot device in the device path for these devices.

10.2 EFI Device Path Protocol

This section provides a detailed description of EFI_DEVICE_PATH_PROTOCOL.

Summary

Can be used on any device handle to obtain generic path/location information concerning the physical device or logical device. If the handle does not logically map to a physical device, the handle may not necessarily support the device path protocol. The device path describes the location of the device the handle is for. The size of the Device Path can be determined from the structures that make up the Device Path.

GUID

```
#define EFI_DEVICE_PATH_PROTOCOL_GUID \
  {0x09576e91,0x6d3f,0x11d2,\
    {0x8e,0x39,0x00,0xa0,0xc9,0x69,0x72,0x3b}}
```

Protocol Interface Structure

```
//*******************************************************
// EFI_DEVICE_PATH_PROTOCOL
//*******************************************************
typedef struct _EFI_DEVICE_PATH_PROTOCOL {
  UINT8           Type;
  UINT8           SubType;
  UINT8           Length[2];
 } EFI_DEVICE_PATH_PROTOCOL;
```

Description

The executing UEFI Image may use the device path to match its own device drivers to the particular device. Note that the executing UEFI OS loader and UEFI application images must access all physical devices via Boot Services device handles until *EFI_BOOT_SERVICES.ExitBootServices()* is successfully called. A UEFI driver may access only a physical device for which it provides functionality.

10.3 Device Path Nodes

There are six major types of Device Path nodes:

- Hardware Device Path. This Device Path defines how a device is attached to the resource domain of a system, where resource domain is simply the shared memory, memory mapped I/O, and I/O space of the system.
- ACPI Device Path. This Device Path is used to describe devices whose enumeration is not described in an industry-standard fashion. These devices must be described using ACPI AML in the ACPI name space; this Device Path is a linkage to the ACPI name space.
- Messaging Device Path. This Device Path is used to describe the connection of devices outside the resource domain of the system. This Device Path can describe physical messaging information such as a SCSI ID, or abstract information such as networking protocol IP addresses.
- Media Device Path. This Device Path is used to describe the portion of a medium that is being abstracted by a boot service. For example, a Media Device Path could define which partition on a hard drive was being used.
- BIOS Boot Specification Device Path. This Device Path is used to point to boot legacy operating systems; it is based on the BIOS Boot Specification Version 1.01. Refer to Appendix Q — References` for details on obtaining this specification.
- End of Hardware Device Path. Depending on the Sub-Type, this Device Path node is used to indicate the end of the Device Path instance or Device Path structure.

10.3.1 Generic Device Path Structures

A Device Path is a variable-length binary structure that is made up of variable-length generic Device Path nodes. *Generic Device Path Node Structure* defines the structure of a variable-length generic Device Path node and the lengths of its components. The table (below) defines the type and sub-type values corresponding to the Device Paths described in *Device Path Nodes*; all other type and sub-type values are Reserved.

Table 10.1: Generic Device Path Node Structure

Mnemonic	**Byte Offset**	**Byte Length**	**Description**
Type	0	1	Type 0x01 - Hardware Device Path Type 0x02 - ACPI Device Path Type 0x03 - Messaging Device Path Type 0x04 - Media Device Path Type 0x05 - BIOS Boot Specification Device Path Type 0x7F - End of Hardware Device Path
Sub-Type	1	1	Sub-Type - Varies by Type. (See table below)
Length	2	2	Length of this structure in bytes. Length is 4 + *n* bytes.
Specific Device Path Data	4	n	Specific Device Path data. Type and Sub-Type define type of data. Size of data is included in Length.

A Device Path is a series of generic Device Path nodes. The first Device Path node starts at byte offset zero of the Device Path. The next Device Path node starts at the end of the previous Device Path node. Therefore all nodes are byte-packed data structures that may appear on any byte boundary. All code references to device path notes must assume all fields are unaligned. Since every Device Path node contains a length field in a known place, it is possible to traverse Device Path nodes that are of an unknown type. There is no limit to the number, type, or sequence of nodes in a Device Path.

A Device Path is terminated by an End of Hardware Device Path node. This type of node has two sub-types (*Device Path End Structures*):

- *End This Instance of a Device Path* (sub-type 0x01). This type of node terminates one Device Path instance and denotes the start of another. This is only required when an environment variable represents multiple devices. An example of this would be the *ConsoleOut* environment variable that consists of both a VGA console and serial output console. This variable would describe a console output stream that is sent to both VGA and serial concurrently and thus has a Device Path that contains two complete Device Paths.
- *End Entire Device Path* (sub-type 0xFF). This type of node terminates an entire Device Path. Software searches for this sub-type to find the end of a Device Path. All Device Paths must end with this sub-type.

Table 10.2: Device Path End Structures

Mnemonic	**Byte Offset**	**Byte Length**	**Description**
Type	0	1	Type 0x7F - End of Hardware Device Path
Sub-Type	1	1	Sub-Type 0xFF - End Entire Device Path, or Sub-Type 0x01 - End This Instance of a Device Path and start a new Device Path
Length	2	2	Length of this structure in bytes. Length is 4 bytes.

10.3.2 Hardware Device Path

This Device Path defines how a device is attached to the resource domain of a system, where resource domain is simply the shared memory, memory mapped I/O, and I/O space of the system. It is possible to have multiple levels of Hardware Device Path such as a PCCARD device that was attached to a PCCARD PCI controller.

10.3.2.1 PCI Device Path

The Device Path for PCI defines the path to the PCI configuration space address for a PCI device. There is one PCI Device Path entry for each device and function number that defines the path from the root PCI bus to the device. Because the PCI bus number of a device may potentially change, a flat encoding of single PCI Device Path entry cannot be used. An example of this is when a PCI device is behind a bridge, and one of the following events occurs:

- OS performs a Plug and Play configuration of the PCI bus.
- A hot plug of a PCI device is performed.
- The system configuration changes between reboots.

The PCI Device Path entry must be preceded by an ACPI Device Path entry that uniquely identifies the PCI root bus. The programming of root PCI bridges is not defined by any PCI specification and this is why an ACPI Device Path entry is required.

Table 10.3: PCI Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 1 - Hardware Device Path
Sub-Type	1	1	Sub-Type 1 - PCI
Length	2	2	Length of this structure is 6 bytes
Function	4	1	PCI Function Number
Device	5	1	PCI Device Number

10.3.2.2 PCCARD Device Path

Pccard Device Path

Table 10.4: PCCARD Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 1 - Hardware Device Path
Sub-Type	1	1	Sub-Type 2 - PCCARD
Length	2	2	Length of this structure in bytes. Length is 5 bytes.
Function Number	4	1	Function Number (0 = First Function)

10.3.2.3 Memory Mapped Device Path

Table 10.5: Memory Mapped Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 1 - Hardware Device Path.
Sub-Type	1	1	Sub-Type 3 - Memory Mapped.
Length	2	2	Length of this structure in bytes. Length is 24 bytes.
Memory Type	4	4	EFI_MEMORY_TYPE. Type EFI_MEMORY_TYPE is defined in the *EFI_BOOT_SERVICES.AllocatePages()* function description.
Start Address	8	8	Starting Memory Address.
End Address	16	8	Ending Memory Address.

10.3.2.4 Vendor Device Path

The Vendor Device Path allows the creation of vendor-defined Device Paths. A vendor must allocate a Vendor GUID for a Device Path. The Vendor GUID can then be used to define the contents on the n bytes that follow in the Vendor Device Path node.

Table 10.6: Vendor-Defined Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 1 - Hardware Device Path.
Sub-Type	1	1	Sub-Type 4 - Vendor.
Length	2	2	Length of this structure in bytes. Length is 20 + n bytes.
Vendor_GUID	4	16	Vendor-assigned GUID that defines the data that follows.
Vendor Defined Data	20	n	Vendor-defined variable size data.

10.3.2.5 Controller Device Path

Table 10.7: Controller Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 1 - Hardware Device Path.
Sub-Type	1	1	Sub-Type 5 - Controller.
Length	2	2	Length of this structure in bytes. Length is 8 bytes.
Controller Number	4	4	Controller number.

10.3.2.6 BMC Device Path

The Device Path for a Baseboard Management Controller (BMC) host interface.

Table 10.8: BMC Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 1 - Hardware Device Path.
Sub-Type	1	1	Sub Type 6 - BMC
Length	2	2	Length of this structure in bytes. Length is 13 bytes.
Interface Type	4	1	The Baseboard Management Controller (BMC) host interface type: 0x00: Unknown 0x01: KCS: Keyboard Controller Style 0x02: SMIC: Server Management Interface Chip 0x03: BT: Block Transfer
Base Address	5	8	Base address (either memory-mapped or I/O) of the BMC. If the le ast-significant bit of the field is a 1, the address is in I/O space; otherwise, the address is memory-mapped. Refer to the IPMI Interface Specification for usage details.

10.3.3 ACPI Device Path

This Device Path contains ACPI Device IDs that represent a device's Plug and Play Hardware ID and its corresponding unique persistent ID. The ACPI IDs are stored in the ACPI _HID, _CID, and _UID device identification objects that are associated with a device. The ACPI Device Path contains values that must match exactly the ACPI name space that is provided by the platform firmware to the operating system. Refer to the ACPI specification for a complete description of the _HID, _CID, and _UID device identification objects.

The _HID and _CID values are optional device identification objects that appear in the ACPI name space. If only _HID is present, the _HID must be used to describe any device that will be enumerated by the ACPI driver. The _CID, if present, contains information that is important for the OS to attach generic driver (e.g., PCI Bus Driver), while the _HID contains information important for the OS to attach device-specific driver. The ACPI bus driver only enumerates a device when no standard bus enumerator exists for a device.

The _UID object provides the OS with a serial number-style ID for a device that does not change across reboots. The object is optional, but is required when a system contains two devices that report the same _HID. The _UID only needs to be unique among all device objects with the same _HID value. If no _UID exists in the APCI name space for a _HID the value of zero must be stored in the _UID field of the ACPI Device Path.

The ACPI Device Path is only used to describe devices that are not defined by a Hardware Device Path. An _HID (along with _CID if present) is required to represent a PCI root bridge, since the PCI specification does not define the programming model for a PCI root bridge. There are two subtypes of the ACPI Device Path: a simple subtype that only includes the _HID and _UID fields, and an extended subtype that includes the _HID, _CID, and _UID fields.

The ACPI Device Path node only supports numeric 32-bit values for the _HID and _UID values. The Expanded ACPI Device Path node supports both numeric and string values for the _HID, _UID, and _CID values. As a result, the ACPI Device Path node is smaller and should be used if possible to reduce the size of device paths that may potentially be stored in nonvolatile storage. If a string value is required for the _HID field, or a string value is required for the _UID field, or a _CID field is required, then the Expanded ACPI Device Path node must be used. If a string field of the Expanded ACPI Device Path node is present, then the corresponding numeric field is ignored.

The _HID and _CID fields in the ACPI Device Path node and Expanded ACPI Device Path node are stored as a 32-bit compressed EISA-type IDs. The following macro can be used to compute these EISA-type IDs from a Plug and Play

Hardware ID. The Plug and Play Hardware IDs used to compute the _HID and _CID fields in the EFI device path nodes must match the Plug and Play Hardware IDs used to build the matching entries in the ACPI tables. The compressed EISA-type IDs produced by this macro differ from the compressed EISA-type IDs stored in ACPI tables. As a result, the compressed EISA-type IDs from the ACPI Device Path nodes cannot be directly compared to the compressed EISA-type IDs from the ACPI table.

```
#define EFI_PNP_ID(ID) (UINT32)(((ID) << 16) | 0x41D0)
#define EISA_PNP_ID(ID) EFI_PNP_ID(ID)
```

Table 10.9: ACPI Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 2 - ACPI Device Path.
Sub-Type	1	1	Sub-Type 1 ACPI Device Path.
Length	2	2	Length of this structure in bytes. Length is 12 bytes.
_HID	4	4	Device's PnP hardware ID stored in a numeric 32-bit compressed EISA-type ID. This value must match the corresponding _HID in the ACPI name space.
_UID	8	4	Unique ID that is required by ACPI if two devices have the same _HID. This value must also match the corresponding _UID/_HID pair in the ACPI name space. Only the 32-bit numeric value type of _UID is supported; thus strings must not be used for the _UID in the ACPI name space.

Table 10.10: Expanded ACPI Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 2 - ACPI Device Path.
Sub-Type	1	1	Sub-Type 2 Expanded ACPI Device Path.
Length	2	2	Length of this structure in bytes. Minimum length is 19 bytes. The actual size will depend on the size of the _HIDSTR, _UIDSTR, and _CIDSTR fields.
_HID	4	4	Device's PnP hardware ID stored in a numeric 32-bit compressed EISA-type ID. This value must match the corresponding _HID in the ACPI name space.
_UID	8	4	Unique ID that is required by ACPI if two devices have the same _HID. This value must also match the corresponding _UID/_HID pair in the ACPI name space.
_CID	12	4	Device's compatible PnP hardware ID stored in a numeric 32-bit compressed EISA-type ID. This value must match at least one of the compatible device IDs returned by the corresponding _CID in the ACPI name space.
_HIDSTR	16	>=1	Device's PnP hardware ID stored as a null-terminated ASCII string. This value must match the corresponding _HID in the ACPI name space. If the length of this string not including the null-terminator is 0, then the _HID field is used. If the length of this null-terminated string is greater than 0, then this field supersedes the _HID field.

continues on next page

Table 10.10 – continued from previous page

_UIDSTR	Varies	>=1	Unique ID that is required by ACPI if two devices have the same _HID. This value must also match the corresponding _UID/_HID pair in the ACPI name space. This value is stored as a null-terminated ASCII string. If the length of this string not including the null-terminator is 0, then the _UID field is used. If the length of this null-terminated string is greater than 0, then this field supersedes the _UID field. The Byte Offset of this field can be computed by adding 16 to the size of the _HIDSTR field.
_CIDSTR	Varies	>=1	Device's compatible PnP hardware ID stored as a null-terminated ASCII string. This value must match at least one of the compatible device IDs returned by the corresponding _CID in the ACPI name space. If the length of this string not including the null-terminator is 0, then the _CID field is used. If the length of this null-terminated string is greater than 0, then this field supersedes the _CID field. The Byte Offset of this field can be computed by adding 16 to the sum of the sizes of the _HIDSTR and _UIDSTR fields.

10.3.3.1 ACPI _ADR Device Path

The _ADR device path is used to contain video output device attributes to support the Graphics Output Protocol. The device path can contain multiple _ADR entries if multiple video output devices are displaying the same output.

Table 10.11: ACPI _ADR Device Path

Mnemonic	**Byte Offset**	**Byte Length**	**Description**
Type	0	1	Type 2 - ACPI Device Path
Sub-Type	1	1	Sub-Type3 _ADR Device Path
Length	2	2	Length of this structure in bytes. Minimum length is 8.
_ADR	4	4	_ADR value. For video output devices the value of this field comes from Table B-2 ACPI 3.0 specification. At least one _ADR value is required
Additional _ADR	8	N	This device path may optionally contain more than one _ADR entry.

10.3.3.2 NVDIMM Device Path

This device path describes an NVDIMM device using the ACPI 6.0 specification defined NFIT Device Handle as the identifier.

Table 10.12: NVDIMM Device Path

Mnemonic	**Byte Offset**	**Byte Length**	**Description**
Type	0	1	Type 2 - ACPI Device Path
Sub-Type	1	1	Sub-type 4 - NVDIMM Device
Length	2	2	8 - Single NFIT Device Handle is supported.
NFIT Device Handle	4	4	NFIT Device Handle - Unique physical identifier. See ACPI Defined Devices and Device Specific Objects section, NVDIMM Devices sub-chapter for the specific definition of the fields utilized for this handle.

10.3.4 Messaging Device Path

This Device Path is used to describe the connection of devices outside the resource domain of the system. This Device Path can describe physical messaging information like SCSI ID, or abstract information like networking protocol IP addresses.

10.3.4.1 ATAPI Device Path

Table 10.13: ATAPI Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 - Messaging Device Path
Sub-Type	1	1	Sub-Type 1 - ATAPI
Length	2	2	Length of this structure in bytes. Length is 8 bytes.
PrimarySecondary	4	1	Set to zero for primary or one for secondary
SlaveMaster	5	1	Set to zero for master or one for slave mode
Logical Unit Number	6	2	Logical Unit Number

10.3.4.2 SCSI Device Path

Table 10.14: SCSI Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 - Messaging Device Path
Sub-Type	1	1	Sub-Type 2 - SCSI
Length	2	2	Length of this structure in bytes. Length is 8 bytes.
Target ID	4	2	Target ID on the SCSI bus (PUN)
Logical Unit Number	6	2	Logical Unit Number (LUN)

10.3.4.3 Fibre Channel Device Path

Table 10.15: Fibre Channel Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 - Messaging Device Path
Sub-Type	1	1	Sub-Type 3 - Fibre Channel
Length	2	2	Length of this structure in bytes. Length is 24 bytes.
Reserved	4	4	Reserved
World Wide Name	8	8	Fibre Channel World Wide Name
Logical Unit Number	16	8	Fibre Channel Logical Unit Number

Table 10.16: Fibre Channel Ex Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 - Messaging Device Path
Sub-Type	1	1	Sub-Type 21 - Fibre Channel Ex
Length	2	2	Length of this structure in bytes. Length is 24 bytes.
Reserved	4	4	Reserved
World Wide Name	8	8	8 byte array containing Fibre Channel End Device Port Name (a.k.a., World Wide Name)
Logical Unit Number	16	8	8 byte array containing Fibre Channel Logical Unit Number

The Fibre Channel Ex device path clarifies the definition of the Logical Unit Number field to conform with the T-10 SCSI Architecture Model 4 specification. The 8 byte Logical Unit Number field in the device path must conform with a logical unit number returned by a SCSI REPORT LUNS command.

When the Fibre Channel Ex Device Path is used with the Extended SCSI Pass Thru Protocol the UINT64 LUN argument must be converted to the eight byte array Logical Unit Number field in the device path by treating the eight byte array as an EFI UINT64.For example a Logical Unit Number array of { 0,1,2,3,4,5,6,7 } becomes a UINT64 of 0x0706050403020100.

When an application client displays or otherwise makes a 64-bit LUN visible to a user, it should be done in conformance with SAM-4. SAM-4 requires a LUN to be displayed in hexadecimal format with byte 0 first (i.e., on the left) and byte 7 last (i.e., on the right) regardless of the internal representation of the LUN. UEFI defines all data structures a "little endian" and SCSI defines all data structures as "big endian".Fibre Channel Ex Device Path Example shows an example device path for a Fibre Channel controller on a typical UEFI platform. This Fibre Channel Controller is connected to the port 0 of the root hub, and its interface number is 0. The Fibre Channel Host Controller is a PCI device whose PCI device number 0x1F and PCI function 0x00. So, the whole device path for this Fibre Channel Controller consists an ACPI Device Path Node, a PCI Device Path Node, a Fibre Channel Device Path Node and a Device Path End Structure. The _HID and _UID must match the ACPI table description of the PCI Root Bridge. The Fibre Channel WWN and LUN were picked to show byte order and they are not typical real world values. The shorthand notation for this device path is:

PciRoot(0)/PCI(31,0)/FibreEx(0x0001020304050607, 0x0001020304050607)

Table 10.17: Fibre Channel Ex Device Path Example

Byte Offset	Byte Length	Data	Description
0	1	0x02	Generic Device Path Header - Type ACPI Device Path
1	1	0x01	Sub type - ACPI Device Path
2	2	0x0C	Length - 0x0C bytes
4	4	0x41D0, 0x0A03	_HID PNP0A03 - 0x41D0 represents the compressed string 'PNP' and is encoded in the low order bytes. The compression method is described in the ACPI Specification.
8	4	0x0000	_UID
12	1	0x01	Generic Device Path Header - Type Hardware Device Path
13	1	0x01	Sub type - PCI
14	2	0x06	Length - 0x06 bytes
16	1	0x0	PCI Function
17	1	0x1F	PCI Device
18	1	0x03	Generic Device Path Header - Type Message Device Path
19	1	0x15	Sub type - Fibre Channel Ex
20	2	0x14	Length - 20 bytes

continues on next page

Table 10.17 – continued from previous page

21	1	0x00	8 byte array containing Fibre Channel End Device Port Name (a.k.a., World Wide Name)
22	1	0x01	
23	1	0x02	
24	1	0x03	
25	1	0x04	
26	1	0x05	
27	1	0x06

32	1	0x03	
33	1	0x04	
34	1	0x05	
35	1	0x06	
36	1	0x07	
37	1	0x7F	Generic Device Path Header - Type End of Hardware Device Path
38	1	0xFF	Sub type - End of Entire Device Path
39	2	0x04	Length - 0x04 bytes

10.3.4.4 1394 Device Path

Table 10.18: 1394 Device Path

Mnemonic	**Byte Offset**	**Byte Length**	**Description**
Type	0	1	Type 3 - Messaging Device Path
Sub-Type	1	1	Sub-Type 4 - 1394
Length	2	2	Length of this structure in bytes. Length is 16 bytes.
Reserved	4	4	Reserved
GUID [1]	8	8	1394 Global Unique ID (GUID) [1]

Note: [1] *The usage of the term GUID is per the 1394 specification. This is not the same as the* EFI_GUID *type defined in the EFI Specification.*

10.3.4.5 USB Device Paths

Table 10.19: USB Device Paths

Mnemonic	**Byte Offset**	**Byte Length**	**Description**
Type	0	1	Type 3 - Messaging Device Path
Sub-Type	1	1	Sub-Type 5 - USB
Length	2	2	Length of this structure in bytes. Length is 6 bytes.
USB Parent Port Number	4	1	USB Parent Port Number
Interface	5	1	USB Interface Number

10.3.4.5.1 USB Device Path Example

USB Device Path Example shows an example device path for a USB controller on a desktop platform. This USB Controller is connected to the port 0 of the root hub, and its interface number is 0. The USB Host Controller is a PCI device whose PCI device number 0x1F and PCI function 0x02. So, the whole device path for this USB Controller consists an ACPI Device Path Node, a PCI Device Path Node, a USB Device Path Node and a Device Path End Structure. The _HID and _UID must match the ACPI table description of the PCI Root Bridge. The shorthand notation for this device path is:

PciRoot(0)/PCI(31,2)/USB(0,0).

Table 10.20: USB Device Path Examples

Byte Offset	Byte length	Data	Description
0x00	0x01	0x02	Generic Device Path Header - Type ACPI Device Path
0x01	0x01	0x01	Sub type - ACPI Device Path
0x02	0x02	0x0C	Length - 0x0C bytes
0x04	0x04	0x41D0, 0x0A03	_HID PNP0A03 - 0x41D0 represents the compressed string ‘PNP’ and is encoded in the low order bytes. The compression method is described in the ACPI Specification.
0x08	0x04	0x0000	_UID
0x0C	0x01	0x01	Generic Device Path Header - Type Hardware Device Path
0x0D	0x01	0x01	Sub type - PCI
0x0E	0x02	0x06	Length - 0x06 bytes
0x10	0x01	0x02	PCI Function
0x11	0x01	0x1F	PCI Device
0x12	0x01	0x03	Generic Device Path Header - Type Message Device Path
0x13	0x01	0x05	Sub type - USB
0x14	0x02	0x06	Length - 0x06 bytes
0x16	0x01	0x00	Parent Hub Port Number
0x17	0x01	0x00	Controller Interface Number
0x18	0x01	0x7F	Generic Device Path Header - Type End of Hardware Device Path
0x19	0x01	0xFF	Sub type - End of Entire Device Path
0x1A	0x02	0x04	Length - 0x04 bytes

Another example is a USB Controller (interface number 0) that is connected to port 3 of a USB Hub Controller (interface number 0), and this USB Hub Controller is connected to the port 1 of the root hub. The shorthand notation for this device path is:

```
PciRoot(0)/PCI(31,2)/USB(1,0)/USB(3,0).
```

See table (below) showing the device path for this USB Controller.

Table 10.21: Another USB Device Path Example

Byte Offset	Byte length	Data	Description
0x00	0x01	0x02	Generic Device Path Header - Type ACPI Device Path
0x01	0x01	0x01	Sub type - ACPI Device Path
0x02	0x02	0x0C	Length - 0x0C bytes

0x19	0x01	0x05	Sub type - USB
0x1A	0x02	0x06	Length - 0x06 bytes
0x1C	0x01	0x03	Parent Hub Port Number
0x1D	0x01	0x00	Controller Interface Number
0x1E	0x01	0x7F	Generic Device Path Header - Type End of Hardware Device Path
0x1F	0x01	0xFF	Sub type - End of Entire Device Path
0x20	0x02	0x04	Length - 0x04 bytes

10.3.4.6 SATA Device Path

Table 10.22: SATA Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 - Messaging Device Path
Sub-Type	1	1	Sub-Type 18 - SATA
Length	2	2	Length of this structure in bytes. Length is 10 bytes.
HBA Port Number	4	2	The HBA port number that facilitates the connection to the device or a port multiplier. The value 0xFFFF is reserved.
Port Multiplier Port Number	6	2	The Port multiplier port number that facilitates the connection to the device. Must be set to 0xFFFF if the device is directly connected to the HBA.
Logical Unit Number	8	2	Logical Unit Number.

10.3.4.7 USB Device Paths (WWID)

This device path describes a USB device using its serial number.

Specifications, such as the USB Mass Storage class, bulk-only transport subclass, require that some portion of the suffix of the device’s serial number be unique with respect to the vendor and product id for the device. So, in order to avoid confusion and overlap of WWID’s, the interface’s class, subclass, and protocol are included.

Table 10.23: USB WWID Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 - Messaging Device Path
Sub-Type	1	1	Sub-Type 16- USB WWID
Length	2	2	Length of this structure in bytes. Length is 10+
• Interface Number	4	2	USB interface number
• Device Vendor Id	6	2	USB vendor id of the device
• Device Product Id	8	2	USB product id of the device
• Serial Number	10	n	Last 64-or-fewer UTF-16 characters of the USB serial number. The length of the string is determined by the Length field less the offset of the Serial Number field (10)

Devices that do not have a serial number string must use the USB Device Path (type 5) as described in *USB Device Path Example*.

Including the interface as part of this node allows distinction for multi-interface devices, e.g., an HID interface and a Mass Storage interface on the same device, or two Mass Storage interfaces.

Load Option Processing defines special rules for processing the USB WWID Device Path. These special rules enable a device location to change and still have the system boot from the device.

10.3.4.8 Device Logical Unit

For some classes of devices, such as USB Mass Storage, it is necessary to specify the Logical Unit Number (LUN), since a single device may have multiple logical units. In order to boot from one of these logical units of the device, the Device Logical Unit device node is appended to the device path. The EFI path node subtype is defined, as in the Table below.

Table 10.24: Device Logical Unit

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 - Messaging Device Path
Sub-Type	1	1	Sub-Type 17 - Device Logical unit
Length	2	2	Length of this structure in bytes. Length is 5
LUN	4	1	Logical Unit Number for the interface

Load Option Processing defines special rules for processing the USB Class Device Path. These special rules enable a device location to change and still have the system recognize the device.

Globally Defined Variables defines how the *ConIn* , *ConOut* , and *ErrOut* variables are processed and contains special rules for processing the USB Class device path. These special rules allow all USB keyboards to be specified as valid input devices.

Table 10.25: USB Class Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 - Messaging Device Path.
Sub-Type	1	1	Sub-Type 15 - USB Class.
Length	2	2	Length of this structure in bytes. Length is 11 bytes.
Vendor ID	4	2	Vendor ID assigned by USB-IF. A value of 0xFFFF will match any Vendor ID.
Product ID	6	2	Product ID assigned by USB-IF. A value of 0xFFFF will match any Product ID.
Device Class	8	1	The class code assigned by the USB-IF. A value of 0xFF will match any class code.
Device Subclass	9	1	The subclass code assigned by the USB-IF. A value of 0xFF will match any subclass code.
Device Protocol	10	1	The protocol code assigned by the USB-IF. A value of 0xFF will match any protocol code.

10.3.4.9 I $_2$ O Device Path

Table 10.26: I $_2$ O Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 - Messaging Device Path
Sub-Type	1	1	Sub-Type 6 - I2O Random Block Storage Class
Length	2	2	Length of this structure in bytes. Length is 8 bytes.
TID	4	4	Target ID (TID) for a device

10.3.4.10 MAC Address Device Path

Table 10.27: MAC Address Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 - Messaging Device Path
Sub-Type	1	1	Sub-Type 11 - MAC Address for a network interface
Length	2	2	Length of this structure in bytes. Length is 37 bytes.
MAC Address	4	32	The MAC address for a network interface padded with 0s
IfType	36	1	Network interface type(i.e., 802.3, FDDI). See RFC 3232

10.3.4.11 IPv4 Device Path

Previous versions of the specification only defined a 19 byte IPv4 device path. To access fields at off-set 19 or greater, the size of the device path must be checked first.

Table 10.28: IPv4 Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 - Messaging Device Path

continues on next page

Table 10.28 – continued from previous page

Sub-Type	1	1	Sub-Type 12 - IPv4
Length	2	2	Length of this structure in bytes. Length is 27 bytes.
Local IP Address	4	4	The local IPv4 address
Remote IP Address	8	4	The remote IPv4 address
Local Port	12	2	The local port number
Remote Port	14	2	The remote port number
Protocol	16	2	The network protocol(i.e., UDP, TCP). See RFC 3232
StaticIPAddress	18	1	0x00 - The Source IP Address was assigned though DHCP 0x01 - The Source IP Address is statically bound
G atewayIPAddress	19	4	The Gateway IP Address
Subnet Mask	23	4	Subnet mask

10.3.4.12 IPv6 Device Path

Table 10.29: IPv6 Device Path

Mnemonic	**Byte Offset**	**Byte Length**	**Description**
Type	0	1	Type 3 - Messaging Device Path
Sub-Type	1	1	Sub-Type 13 - IPv6
Length	2	2	Length of this structure in bytes. Length is 60 bytes.
Local IP Address	4	16	The local IPv6 address
Remote IP Address	20	16	The remote IPv6 address
Local Port	36	2	The local port number
Remote Port	38	2	The remote port number
Protocol	40	2	The network protocol (i.e., UDP, TCP). See RFC 3232
IPAddressOrigin	42	1	0x00 - The Local IP Address was manually configured. 0x01 - The Local IP Address is assigned through IPv6 stateless auto -configuration. 0x02 - The Local IP Address is assigned through IPv6stateful configuration.
PrefixLength	43	1	The Prefix Length
GatewayIPAddress	44	16	The Gateway IP Address

10.3.4.13 2. VLAN device path node

Table 10.30: VLAN device path node

Mnemonic	**Byte Offset**	**Byte Length**	**Description**
Type	0	1	Type 3 - Messaging Device Path
Sub-Type	1	1	Sub-Type 20 - Vlan (802.1q)
Length	2	2	Length of this device node
Vlanid	4	2	VLAN identifier (0-4094)

10.3.4.14 InfiniBand Device Path

Table 10.31: InfiniBand Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 - Messaging Device Path
Sub-Type	1	1	Sub-Type 9 - InfiniBand
Length	2	2	Length of this structure in bytes. Length is 48 bytes.
Resource Flags	4	4	Flags to help identify/manage InfiniBand device path elements: • Bit 0: IOC/Service (0b = IOC, 1b = Service) • Bit 1: Extend Boot Environment • Bit 2: Console Protocol • Bit 3: Storage Protocol • Bit 4: Network Protocol All other bits are reserved.
PORT GID	8	16	128-bit Global Identifier for remote fabric port
IOC GUID/Service ID	24	8	64-bit unique identifier to remote IOC or server process. Interpretation of field specified by Resource Flags (bit 0)
Target Port ID	32	8	64-bit persistent ID of remote IOC port
Device ID	40	8	64-bit persistent ID of remote device

Note: *The usage of the terms GUID and GID is per the InfiniBand Specification. The term GUID is not the same as the* EFI_GUID *type defined in this EFI Specification.*

10.3.4.15 UART Device Path

Table 10.32: UART Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 – Messaging Device Path
Sub-Type	1	1	Sub-Type 14 – UART
Length	2	2	Length of this structure in bytes. Length is 19 bytes.
Reserved	4	4	Reserved
Baud Rate	8	8	The baud rate setting for the UART style device. A value of 0 means that the device's default baud rate will be used.
Data Bits	16	1	The number of data bits for the UART style device. A value of 0 means that the device's default number of data bits will be used.

continues on next page

Table 10.32 – continued from previous page

Parity	17	1	The parity setting for the UART style device. Parity 0x00 - Default Parity Parity 0x01 - No Parity Parity 0x02 - Even Parity Parity 0x03 - Odd Parity Parity 0x04 - Mark Parity Parity 0x05 - Space Parity
Stop Bits	18	1	The number of stop bits for the UART style device. Stop Bits 0x00 - Default Stop Bits Stop Bits 0x01 - 1 Stop Bit Stop Bits 0x02 - 1.5 Stop Bits Stop Bits 0x03 - 2 Stop Bits

10.3.4.16 Vendor-Defined Messaging Device Path

Table 10.33: Vendor-Defined Messaging Device Path

Mnemonic	**Byte Offset**	**Byte Length**	**Description**
Type	0	1	Type 3 - Messaging Device Path
Sub-Type	1	1	Sub-Type 10 - Vendor
Length	2	2	Length of this structure in bytes. Length is 20 + n bytes.
Vendor GUID	4	16	Vendor-assigned GUID that defines the data that follows
Vendor Defined Data	20	n	Vendor-defined variable size data

The following GUIDs are used with a Vendor-Defined Messaging Device Path to describe the transport protocol for use with PC-ANSI, VT-100, VT-100+, and VT-UTF8 terminals. Device paths can be constructed with this node as the last node in the device path. The rest of the device path describes the physical device that is being used to transmit and receive data. The PC-ANSI, VT-100, VT-100+, and VT-UTF8 GUIDs define the format of the data that is being sent though the physical device. Additional GUIDs can be generated to describe additional transport protocols.

```
#define EFI_PC_ANSI_GUID\
 {0xe0c14753,0xf9be,0x11d2,{0x9a,0x0c,0x00,0x90,0x27,0x3f,0xc1,0x4d}}

#define EFI_VT_100_GUID\
 {0xdfa66065,0xb419,0x11d3,{0x9a,0x2d,0x00,0x90,0x27,0x3f,0xc1,0x4d}}

#define EFI_VT_100_PLUS_GUID\
 {0x7baec70b,0x57e0,0x4c76,{0x8e,0x87,0x2f,0x9e,0x28,0x08,0x83,0x43}}

#define EFI_VT_UTF8_GUID\
 {0xad15a0d6,0x8bec,0x4acf,{0xa0,0x73,0xd0,0x1d,0xe7,0x7e,0x2d,0x88}}
```

10.3.4.17 UART Flow Control Messaging Path

The UART messaging device path defined in the EFI 1.02 specification does not contain a provision for flow control. Therefore, a new device path node is needed to declare flow control characteristics. It is a vendor-defined messaging node which may be appended to the UART node in a device path. It has the following definition:

```
#define DEVICE_PATH_MESSAGING_UART_FLOW_CONTROL \
{0x37499a9d,0x542f,0x4c89,{0xa0,0x26,0x35,0xda,0x14,0x20,0x94,0xe4}}
```

Table 10.34: UART Flow Control Messaging Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 - Messaging Device Path
Sub-Type	1	1	Sub-Type 10 - Vendor
Length	2	2	Length of this structure in bytes. Length is 24 bytes.
Vendor GUID	4	16	DEVICE_PATH_MESSAGING_UART_FLOW_CONTROL
Flow_Control_Map	20	4	Bitmap of supported flow control types. • Bit 0 set indicates hardware flow control. • Bit 1 set indicates Xon/Xoff flow control. • All other bits are reserved and are clear.

A debugport driver that implements Xon/Xoff flow control would produce a device path similar to the following:

```
PciRoot(0)/Pci(0x1f,0)/ACPI(PNP0501,0)/UART(115200,N,8,1)/UartFlowCtrl(2)/DebugPort()
```

Note: If no bits are set in the Flow_Control_Map, this indicates there is no flow control and is equivalent to leaving the flow control node out of the device path completely.

10.3.4.18 Serial Attached SCSI (SAS) Device Path

This section defines the device node for Serial Attached SCSI (SAS) devices.

Table 10.35: SAS Messaging Device Path Structure

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type -3 Messaging
Sub Type	1	1	10 (Vendor)
Length	2	2	Length of this Structure.
Vendor GUID	4	16	d487dd b4-008b-11d9-af dc-001083ffca4d
Reserved	20	4	Reserved for future use.
SAS Address	24	8	SAS Address for Serial Attached SCSI Target.
Logical Unit Number	32	8	SAS Logical Unit Number.
SAS/SATA device and Topology Info	40	2	More Information about the device and its interconnect
Relative Target Port	42	2	Relative Target Port (RTP)

Summary

The device node represented by the structure in the table above shall be appended after the Hardware Device Path node in the device path.

There are two cases for boot devices connected with SAS HBA's. Each of the cases is described below with an example of the expected Device Path for these.

- SAS Device anywhere in an SAS domain accessed through SSP Protocol.

```
PciRoot(0)/PCI(1,0)/Sas(0x31000004CF13F6BD, 0)
```

The first 64-bit number represents the SAS address of the target SAS device.

The second number is the boot LUN of the target SAS device.

The third number is the Relative Target Port (RTP)

- SATA Device connected directly to a HBA port.

```
PciRoot(0)/PCI(1,0)/Sas(0x31000004CF13F6BD)
```

The first number represents either a real SAS address reserved by the HBA for above connections, or a fake but unique SAS address generated by the HBA to represent the SATA device.

10.3.4.18.1 Device and Topology Information

First Byte (At offset 40 into the structure):

Bits 0:3:

Value 0x0 -> No Additional Information about device topology.

Value 0x1 -> More Information about device topology valid in this byte.

Value 0x2 -> More Information about device topology valid in this and next 1 byte.

Values 0x3 thru 0xF -> Reserved.

Bits 4:5: Device Type (Valid only if the More Information field above is non-zero)

Value 0x0 -> SAS Internal Device

Value 0x1 -> SATA Internal Device

Value 0x2 -> SAS External Device

Value 0x3 -> SATA External Device

Bits 6:7: Topology / Interconnect (Valid only if the More Information field above is non-zero)

Value 0x0 -> Direct Connect (Connected directly with the HBA Port/Phy)

Value 0x1 -> Expander Connect (Connected thru/via one or more Expanders)

Value 0x2 and 0x3 > Reserved

10.3.4.18.2 Device and Topology Information

Second Byte (At offset 41 into the structure). Valid only if bits 0-3 of More Information in Byte 40 have a value of 2:

Bits 0-7: Internal Drive/Bay Id (Only applicable if Internal Drive is indicated in Device Type)

Value 0x0 thru 0xFF -> Drive 1 thru Drive 256

10.3.4.18.3 Relative Target Port

At offset 42 into the structure:

This two-byte field shall contain the "Relative Target Port" of the target SAS port. Relative Target Port can be obtained by performing an INQUIRY command to VPD page 0x83 in the target. Implementation of RTP is mandatory for SAS targets as defined in Section 10.2.10 of sas1r07 specification (or later).

NOTE: *If a LUN is seen thru multiple RTPs in a given target, then the UEFI driver shall create separate device path instances for both paths. RTP in the device path shall distinguish these two device path instantiations.*

NOTE: *Changing the values of the SAS/SATA device topology information or the RTP fields of the device path will make UEFI think this is a different device.*

10.3.4.18.4 Examples Of Correct Device Path Display Format

Case 1: When Additional Information is not Valid or Not Present (Bits 0:3 of Byte 40 have a value of 0)

```
PciRoot(0)/PCI(1,0)/SAS(0x31000004CF13F6BD, 0)
```

Case 2: When Additional Information is Valid and present (Bits 0:3 of Byte 40 have a value of 1 or 2)

- If Bits 4-5 of Byte 40 (Device and Topology information) indicate an SAS device (Internal or External) i.e., has values 0x0 or 0x2, then the following format shall be used.

```
PciRoot(0)/PCI(1,0)/SAS(0x31000004CF13F6BD, 0, SAS)
```

- If Bits 4-5 of Byte 40 (Device and Topology information) indicate a SATA device (Internal or External) i.e., has a value of 0x1 or 0x3, then the following format shall be used.

```
ACPI(PnP)/PCI(1,0)/SAS(0x31000004CF13F6BD, SATA)
```

10.3.4.19 Serial Attached SCSI (SAS) Extended Device Path

This section defines the extended device node for Serial Attached SCSI (SAS) devices. In this device path the SAS Address and LUN are now defined as arrays to remove the need to endian swap the values.

Table 10.36: SAS Extended Messaging Device Path Structure

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type -3 Messaging
Sub Type	1	1	Sub-type 22 SAS Ex
Length	2	2	Length of this Structure. 32 bytes

continues on next page

Table 10.36 – continued from previous page

SAS Address	4	8	8-byte array of the SAS Address for Serial Attached SCSI Target Port.
Logical Unit Number	20	8	8-byte array of the SAS Logical Unit Number.
SAS/SATA device and Topology Info	28	2	More Information about the device and its interconnect
Relative Target Port	30	2	Relative Target Port (RTP)

The SAS Ex device path clarifies the definition of the Logical Unit Number field to conform with the T-10 SCSI Architecture Model 4 specification. The 8 byte Logical Unit Number field in the device path must conform with a logical unit number returned by a SCSI REPORT LUNS command.

When the SAS Device Path Ex is used with the Extended SCSI Pass Thru Protocol, the UINT64 LUN must be converted to the eight byte array Logical Unit Number field in the device path by treating the eight byte array as an EFI UINT64. For example, a Logical Unit Number array of { 0,1,2,3,4,5,6,7 } becomes a UINT64 of 0x0706050403020100.

When an application client displays or otherwise makes a 64-bit LUN (8 byte array) visible to a user, it should be done in conformance with SAM-4. SAM-4 requires a LUN to be displayed in hexadecimal format with byte 0 first (i.e., on the left) and byte 7 last (i.e., on the right) regardless of the internal representation of the LUN. UEFI defines all data structures a "little endian" and SCSI defines all data structures as "big endian".

10.3.4.20 iSCSI Device Path

Table 10.37: iSCSI Device Path Node (Base Information)

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 - Messaging Device Path
Sub-Type	1	1	Sub-Type 19 - (iSCSI)
Length	2	2	Length of this structure in bytes. Length is (18 + n) bytes
Protocol	4	2	Network Protocol (0 = TCP, 1+ = reserved)
Options	6	2	iSCSI Login Options
Logical Unit Number	8	8	8 byte array containing the iSCSI Logical Unit Number
Target Portal group tag	16	2	iSCSI Target Portal group tag the initiator intends to establish a session with.
iSCSI Target Name	18	n	iSCSI NodeTarget Name. The length of the name is determined by subtracting the offset of this field from Length.

10.3.4.20.1 iSCSI Login Options

The iSCSI Device Node Options describe the iSCSI login options for the key values:

Bits 0:1:

0 = No Header Digest

2 = Header Digest Using CRC32C

Bits 2-3:

0 = No Data Digest

2 = Data Digest Using CRC32C

Bits 4-9:

Reserved for future use

Bits 10-11:

0 = AuthMethod_CHAP

2 = AuthMethod_None

Bit 12:

0 = CHAP_BI

1 = CHAP_UNI

For each specific login key, none, some or all of the defined values may be configured. If none of the options are defined for a specific key, the iSCSI driver shall propose "None" as the value. If more than one option is configured for a specific key, all the configured values will be proposed (ordering of the values is implementation dependent).

- Portal Group Tag: defines the iSCSI portal group the initiator intends to establish Session with.
- Logical Unit Number: defines the 8 byte SCSI LUN. The Logical Unit Number field must conform to the T-10 SCSI Architecture Model 4 specification. The 8 byte Logical Unit Number field in the device path must conform with a logical unit number returned by a SCSI REPORT LUNS command.
- iSCSI Target Name: defines the iSCSI Target Name for the iSCSI Node. The size of the iSCSI Target Name can be up to a maximum of 223 bytes.

10.3.4.20.2 Device Path Examples

Some examples for the Device Path for the case the boot device connected to iSCSI bootable controller:

- With IPv4 configuration:

```
PciRoot(0)/Pci(19|0)/Mac( 001320F5FA77,0x01)/
IPv4(192.168.0.100,TCP,Static,192.168.0.1)/ iSCSI(iqn.1991-
05.com.microsoft:iscsitarget-iscsidisk-target,0x1,0x0,None,None,None,TCP)/
HD(1,GPT,15E39A00-1DD2-1000-8D7F-00A0C92408FC,0x22,0x2710000)
```

Table 10.38: IPv4 configuration

Byte Offset	Byte Length	Data	Description
0x00	1	0x02	Generic Device Path Header - Type ACPI Device Path
0x01	1	0x01	Sub type - ACPI Device Path
0x02	2	0x0C	Length - 0x0C bytes
0x04	4	0x41D0, 0x0A03	_HID PNP0A03 - 0x41D0 represents the compressed string 'PNP' and is encoded in the low order bytes. The compression method is described in the ACPI Specification.
0x08	4	0x0000	_UID
0x0C	1	0x01	Generic Device Path Header - Type Hardware Device Path
0x0D	1	0x01	Sub type - PCI
0x0E	2	0x06	Length - 0x06 bytes
0x10	1	0x0	PCI Function
0x11	1	0x19	PCI Device
0x12	1	0x03	Generic Device Path Header - Messaging Device Path

10.3.4.21 NVM Express namespace messaging device path node

Table 10.40: NVM Express Namespace Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 - Messaging Device Path
Sub-Type	1	1	Sub Type 23 - NVM Express Namespace
Length	2	2	Length of this structure in bytes. Length is 16 bytes.
Namespace Identifier	4	4	Namespace identifier (NSID). The values of 0 and 0xFFFFFFFF are invalid.
IEEE Extended Unique Identifier	8	8	This field contains the IEEE Extended Unique Identifier (EUI-64). Devices without an EUI-64 value must initialize this field with a value of 0.

Refer to the latest NVM Express specification for descriptions of Namespace Identifier (NSID) and IEEE Extended Unique Identifier (EUI-64):See “Links to UEFI-Related Documents” (http://www.nvmexpress.org/index) under the heading “NVMe Specification”.

Note: When an application client displays or otherwise makes the EUI-64 identifiers visible to a user, the values should be displayed in hexadecimal format with byte 7 first (i.e., on the left) and byte 0 last (i.e., on the right) regardless of the internal representation of the EUI-64.

10.3.4.22 Uniform Resource Identifiers (URI) Device Path

Refer to RFC 3986 for details on the URI contents.

Table 10.41: URI Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 - Messaging Device Path
Sub-Type	1	1	Sub Type 24 - Universal Resource Identifier (URI) Device Path
Length	2	2	Length of this structure in bytes. Length is 4 + n bytes.
…	4	n	Instance of the URI pursuant to RFC 3986. For an empty URI, Length is 4 bytes.

10.3.4.23 UFS (Universal Flash Storage) device messaging devicepath node

Table 10.42: UFS Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 - Messaging Device Path
Sub-Type	1	1	Sub-Type 25 - UFS
Length	2	2	Length of this structure in bytes. Length is 6 bytes.
Target ID	4	1	Target ID on the UFS interface (PUN).
LUN	5	1	Logical Unit Number (LUN).

Refer to the UFS 2.0 specification for additional LUN descriptions: See “Links to UEFI-Related Documents” (http://uefi.org/uefi) under the heading “UFS 2.0 Specification”.

- *PUN field* : According to current available UFS 2.0 spec, the topology is one device per UFS port. A topology to support multiple devices on a single interface is planned for future revision. So suggest to reserve/introduce this field to support multiple devices per UFS port. This value should be 0 for current UFS2.0 spec compliance.
- *LUN field* : This field is used to specify up to 8 normal LUNs(0-7) and 4 well-known LUNs(81h, D0h, B0h and C4h). For those well-known LUNs, the BIT7 is set. See Figure 10.2 of UFS 2.0 spec for details.

10.3.4.24 SD (Secure Digital) Device Path

Table 10.43: SD Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 - Messaging Device Path
Sub-Type	1	1	Sub-Type 26 - SD
Length	2	2	Length of this structure in bytes. Length is 5 bytes.
Slot Number	4	1	Slot Number

10.3.4.25 EFI Bluetooth Device Path

Table 10.44: EFI Bluetooth Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 - Messaging Device Path
Sub-Type	1	1	Sub-Type 27 - Bluetooth
Length	2	2	Length of this structure in bytes. Length is 10 bytes.
Bluetooth Device Address	4	6	48-bit Bluetooth device address.

10.3.4.26 Wireless Device Path

10.3.4.27 eMMC (Embedded Multi-Media Card) Device Path

Table 10.45: eMMC Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 - Messaging Device Path
Sub-Type	1	1	Sub-Type 29 - eMMC
Length	2	2	Length of this structure in bytes. Length is 5 bytes.
Slot Number	4	1	Slot Number

10.3.4.28 EFI BluetoothLE Device Path

Table 10.46: EFI BluetoothLE Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 - Messaging Device Path
Sub-Type	1	1	Sub-Type 30 - BluetoothLE
Length	2	2	Length of this structure in bytes. Length is 11 bytes.
Bluetooth Device Address	4	6	48-bit Bluetooth device address
Address Type	10	1	0x00 - Public Device Address | 0x01 - Random Device Address

10.3.4.29 DNS Device Path

Table 10.47: DNS Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 - Messaging Device Path
Sub-Type	1	1	Sub-Type 31 - DNS Device Path
Length	2	2	Length of this structure in bytes. Length is 5 + n bytes.
IsIPv6	4	1	0x00 - The DNS server address is IPv4 address. 0x01 - The DNS server address is IPv6 address.

continues on next page

Table 10.47 – continued from previous page

...	5	n	One or more instances of the DNS server address in EFI_IP_ADDRESS.

10.3.4.30 NVDIMM Namespace path

This device path describes a bootable NVDIMM namespace that is defined by a namespace label. The presence of this type of device path indicates that UEFI supports booting to the namespace including any address abstraction specified by the namespace label. Refer to the NVDIMM Label Protocol section to retrieve relevant details about the namespace.

Table 10.48: NVDIMM Namespace Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 - Messaging Device
Sub-Type	1	1	Sub-type 32 - NVDIMM Namespace
Length	2	2	20 - Single namespace UUID is supported.
Uuid	4	16	Namespace unique label identifier UUID. See the Uuid description in the NVDIMM Label Protocol - Label definitions section for details on this field.

10.3.4.31 REST Service Device Path

Table 10.49: REST Service Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 0x03 - Messaging Device Path
Sub-Type	1	1	Sub-Type 33- REST Service Device Path
Length	2	2	Length of this structure in bytes. Length is 6 bytes.
REST Service	4	1	0x01 = Redfish REST Service - 0x02 = OData REST Service
Access Mode	5	1	(0x01) In-Band REST Service, - (0x02) Out-of-band REST Service.

Device path example of Out-of-band Redfish REST Service through NIC:

```
PciRoot(0x2)/Pci(0x2,0x0)/Pci(0x0,0x0)/MAC(FD19FA100672,0x0)/
IPv4(0.0.0.0,0x0,DHCP,0.0.0.0,0.0.0.0,0.0.0.0)/RestService(1,2)
```

Table 10.50: Vendor-Specific REST Service Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 0x03 - Messaging Device Path
Sub-Type	1	1	Sub-Type 33- REST Service Device Path
Length	2	2	Length of this structure in bytes. Length is 21 + n bytes.
REST Service	4	1	0xFF = Vendor specific REST Service
Access Mode	5	1	(0x01) In-Band REST Service, (0x02) Out-of-band REST Service.
Vendor specific REST service GUID	6	16	GUID of vendor specific REST service.

continues on next page

Table 10.50 – continued from previous page

Vendor defined data	22	n	Vendor-defined data.

Device path example of In-band vendor-specific REST Service through BMC:

```
PciRoot(0x2)/Pci(0x2,0x0)/Pci(0x0,0x0)/BMC(0,0xf0000000)/RestService(0xff, 1,
00000000-0000-0000-0000000000000000,0,0)
```

10.3.5 Media Device Path

This Device Path is used to describe the portion of the medium that is being abstracted by a boot service. An example of Media Device Path would be defining which partition on a hard drive was being used.

10.3.5.1 Hard Drive

The Hard Drive Media Device Path is used to represent a partition on a hard drive. Each partition has at least Hard Drive Device Path node, each describing an entry in a partition table. EFI supports MBR and GPT partitioning formats. Partitions are numbered according to their entry in their respective partition table, starting with 1. Partitions are addressed in EFI starting at LBA zero. A partition number of zero can be used to represent the raw hard drive or a raw extended partition

The partition format is stored in the Device Path to allow new partition formats to be supported in the future. The Hard Drive Device Path also contains a Disk Signature and a Disk Signature Type. The disk signature is maintained by the OS and only used by EFI to partition Device Path nodes. The disk signature enables the OS to find disks even after they have been physically moved in a system.

Load Option Processing defines special rules for processing the Hard Drive Media Device Path. These special rules enable a disk's location to change and still have the system boot from the disk.

Table 10.51: Hard Drive Media Device Path

Mnemonic	**Byte Offset**	**Byte Length**	**Description**
Type	0	1	Type 4 — Media Device Path
Sub-Type	1	1	Sub-Type 1 — Hard Drive
Length	2	2	Length of this structure in bytes. Length is 42 bytes.
Partition Number	4	4	Describes the entry in a partition table, starting with entry 1. Partition number zero represents the entire device. Valid partition numbers for a MBR partition are [1, 4]. Valid partition numbers for a GPT partition are [1, NumberOfPar titionEntries].
Partition Start	8	8	Starting LBA of the partition on the hard drive
Partition Size	16	8	Size of the partition in units of Logical Blocks
Partition Signature	24	16	Signature unique to this partition: If SignatureType is 0, this field has to be initialized with 16 zeroes. If SignatureType is 1, the MBR signature is stored in the first 4 bytes of this field. The other 12 bytes are initialized with zeroes. If SignatureType is 2, this field contains a 16 byte signature.
Partition Format	40	1	Partition Format: (Unused values reserved) 0x01 - PC-AT compatible legacy MBR (*Legacy MBR*) . Partition Start and Partition Size come from *Parti tionStartingLBA* and *PartitionSizeInLBA* for the partition.0x02—GUID Partition Table

continues on next page

Table 10.51 – continued from previous page

Signature Type	41	1	Type of Disk Signature: (Unused values reserved) 0x00 - No Disk Signature. 0x01 - 32-bit signature from address 0x1b8 of the type 0x01 MBR. 0x02 - GUID signature.

10.3.5.2 CD-ROM Media Device Path

The CD-ROM Media Device Path is used to define a system partition that exists on a CD-ROM. The CD-ROM is assumed to contain an ISO-9660 file system and follow the CD-ROM “El Torito” format. The Boot Entry number from the Boot Catalog is how the “El Torito” specification defines the existence of bootable entities on a CD-ROM. In EFI the bootable entity is an EFI System Partition that is pointed to by the Boot Entry.

Table 10.52: CD-ROM Media Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 4 - Media Device Path.
Sub-Type	1	1	Sub-Type 2 - CD-ROM “El Torito” Format.
Length	2	2	Length of this structure in bytes. Length is 24 bytes.
Boot Entry	4	4	Boot Entry number from the Boot Catalog. The Initial/Default entry is defined as zero.
Partition Start	8	8	Starting RBA of the partition on the medium. CD-ROMs use Relative logical Block Addressing.
Partition Size	16	8	Size of the partition in units of Blocks, also called Sectors.

10.3.5.3 Vendor-Defined Media Device Path

Table 10.53: Vendor-Defined Media Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 4 - Media Device Path.
Sub-Type	1	1	Sub-Type 3 - Vendor.
Length	2	2	Length of this structure in bytes. Length is 20 + n bytes.
Vendor GUID	4	16	Vendor-assigned GUID that defines the data that follows.
Vendor Defined Data	20	n	Vendor-defined variable size data.

10.3.5.4 File Path Media Device Path

Table 10.54: File Path Media Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 4 - Media Device Path.
Sub-Type	1	1	Sub-Type 4 - File Path.
Length	2	2	Length of this structure in bytes. Length is 4 + *n* bytes.

continues on next page

Table 10.54 – continued from previous page

Path Name	4	*N*	A NULL-terminated Path string including directory and file names. The length of this string n can be determined by subtracting 4 from the Length entry. A device path may contain one or more of these nodes. Each node can optionally add a “" separator to the beginning and/or the end of the Path Name string. The complete path to a file can be found by logically concatenating all the Path Name strings in the File Path Media Device Path nodes. This is typically used to describe the directory path in one node, and the filename in another node.

Rules for Path Name conversion:

- When concatenating two Path Names, ensure that the resulting string does not contain a double-separator “\”. If it does, convert that double-separator to a single-separator.
- In the case where a Path Name which has no end separator is being concatenated to a Path Name with no beginning separator, a separator will need to be inserted between the Path Names.
- Single file path nodes with no directory path data are presumed to have their files located in the root directory of the device.

10.3.5.5 Media Protocol Device Path

The Media Protocol Device Path is used to denote the protocol that is being used in a device path at the location of the path specified. Many protocols are inherent to the style of device path.

Table 10.55: Media Protocol Media Device Path

Mnemonic	**Byte Offset**	**Byte Length**	**Description**
Type	0	1	Type 4 - Media Device Path.
Sub-Type	1	1	Sub-Type 5 - Media Protocol.
Length	2	2	Length of this structure in bytes. Length is 20 bytes.
Protocol GUID	4	16	The ID of the protocol.

10.3.5.6 PIWG Firmware File

This type is used by systems implementing the UEFI PI Specification to describe a firmware file. The exact format and usage are defined in that specification.

Table 10.56: PIWG Firmware File Device Path

Mnemonic	**Byte Offset**	**Byte Length**	**Description**
Type	0	1	Type 4 - Media Device Path.
Sub-Type	1	1	Sub-Type 6 - PIWG Firmware File.
Length	2	2	Length of this structure in bytes. Length is 4 + *n* bytes.
…	4	n	Contents are defined in the UEFI PI Specification.

10.3.5.7 PIWG Firmware Volume

This type is used by systems implementing the UEFI PI Specification to describe a firmware volume. The exact format and usage are defined in that specification.

Table 10.57: PIWG Firmware Volume Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 4 - Media Device Path.
Sub-Type	1	1	Sub-Type 7 - PIWG Firmware Volume.
Length	2	2	Length of this structure in bytes. Length is 4 + *n* bytes.
…	4	n	Contents are defined in the UEFI PI Specification.

10.3.5.8 Relative Offset Range

This device path node specifies a range of offsets relative to the first byte available on the device. The starting offset is the first byte of the range and the ending offset is the last byte of the range (not the last byte + 1).

Table 10.58: Relative Offset Range

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 4 - Media Device Path
Sub-Type	1	1	Sub-Type 8 - Relative Offset Range
Length	2	2	Length of this structure in bytes.
Reserved	4	4	Reserved for future use.
Starting Offset	8	8	Offset of the first byte, relative to the parent device node.
Ending Offset	16	8	Offset of the last byte, relative to the parent device node.

10.3.5.9 RAM Disk

Table 10.59: RAM Disk Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 4 - Media Device Path
Sub-Type	1	1	Sub Type 9 - RAM Disk Device Path
Length	2	2	Length of this structure in bytes. Length is 38 bytes.
Starting Address	4	8	Starting Memory Address.
Ending Address	12	8	Ending Memory Address.
Disk Type GUID	20	16	GUID that defines the type of the RAM Disk. The GUID can be any of the values defined below, or a vendor defined GUID.
Disk Instance	36	2	RAM Disk instance number, if supported. The default value is zero.

The following GUIDs are used with a RAM Disk Device Path to describe the RAM Disk Type. Additional GUIDs can be generated to describe additional RAM Disk Types. The Disk Type GUID values used in the RAM Disk device path must match the corresponding values in the Address Range Type GUID of the ACPI NFIT table. Refer to the ACPI specification for details.

This GUID defines a RAM Disk supporting a raw disk format in volatile memory:

```
#define EFI_VIRTUAL_DISK_GUID \
{ 0x77AB535A,0x45FC,0x624B,\
{0x55,0x60,0xF7,0xB2,0x81,0xD1,0xF9,0x6E }}
```

This GUID defines a RAM Disk supporting an ISO image in volatile memory:

```
#define EFI_VIRTUAL_CD_GUID \
{ 0x3D5ABD30,0x4175,0x87CE,\
{0x6D,0x64,0xD2,0xAD,0xE5,0x23,0xC4,0xBB }}
```

This GUID defines a RAM Disk supporting a raw disk format in persistent memory:

```
#define EFI_PERSISTENT_VIRTUAL_DISK_GUID \
{ 0x5CEA02C9,0x4D07,0x69D3,\
{0x26,0x9F,0x44,0x96,0xFB,0xE0,0x96,0xF9 }}
```

This GUID defines a RAM Disk supporting an ISO image in persistent memory:

```
#define EFI_PERSISTENT_VIRTUAL_CD_GUID \
{ 0x08018188,0x42CD,0xBB48,\
{0x10,0x0F,0x53,0x87,0xD5,0x3D,0xED,0x3D }}
```

10.3.6 BIOS Boot Specification Device Path

This Device Path is used to describe the booting of non-EFI-aware operating systems. This Device Path is based on the IPL and BCV table entry data structures defined in Appendix A of the *BIOS Boot Specification*. The BIOS Boot Specification Device Path defines a complete Device Path and is not used with other Device Path entries. This Device Path is only needed to enable platform firmware to select a legacy non-EFI OS as a boot option.

Table 10.60: BIOS Boot Specification Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 5 - BIOS Boot Specification Device Path.
Sub-Type	1	1	Sub-Type 1 - BIOS Boot Specification Version 1.01.
Length	2	2	Length of this structure in bytes. Length is 8 + n bytes.
Device Type	4	2	Device Type as defined by the BIOS Boot Specification.
Status Flag	6	2	Status Flags as defined by the BIOS Boot Specification
Description String	8	n	A null-terminated ASCII string that describes the boot device to a user. The size of this string *n* can be determined by subtracting 8 from the Length entry.

Example BIOS Boot Specification Device Types include:

- 00h = Reserved
- 01h = Floppy
- 02h = Hard Disk
- 03h = CD-ROM
- 04h = PCMCIA
- 05h = USB

- 06h = Embedded network
- 07h..7Fh = Reserved
- 80h = BEV device
- 81h..FEh = Reserved
- FFh = Unknown

NOTE: *When UEFI Secure Boot is enabled, attempts to boot non-UEFI OS shall fail*; *Firmware/OS Key Exchange: Passing Public Keys* .

10.4 Device Path Generation Rules

10.4.1 Housekeeping Rules

The Device Path is a set of Device Path nodes. The Device Path must be terminated by an End of Device Path node with a sub-type of End the Entire Device Path. A NULL Device Path consists of a single End Device Path Node. A Device Path that contains a NULL pointer and no Device Path structures is illegal.

All Device Path nodes start with the generic Device Path structure. Unknown Device Path types can be skipped when parsing the Device Path since the length field can be used to find the next Device Path structure in the stream. Any future additions to the Device Path structure types will always start with the current standard header. The size of a Device Path can be determined by traversing the generic Device Path structures in each header and adding up the total size of the Device Path. This size will include the four bytes of the End of Device Path structure.

Multiple hardware devices may be pointed to by a single Device Path. Each hardware device will contain a complete Device Path that is terminated by the Device Path End Structure. The Device Path End Structures that do not end the Device Path contain a sub-type of End This Instance of the Device Path. The last Device Path End Structure contains a sub-type of End Entire Device Path.

10.4.2 Rules with ACPI _HID and _UID

As described in the ACPI specification, ACPI supports several different kinds of device identification objects, including _HID, _CID and _UID. The _UID device identification objects are optional in ACPI and only required if more than one _HID exists with the same ID. The ACPI Device Path structure must contain a zero in the _UID field if the ACPI name space does not implement _UID. The _UID field is a unique serial number that persists across reboots.

If a device in the ACPI name space has a _HID and is described by a _CRS (Current Resource Setting) then it should be described by an ACPI Device Path structure. A _CRS implies that a device not mapped by any other standard. A _CRS is used by ACPI to make a nonstandard device into a Plug and Play device. The configuration methods in the ACPI name space allow the ACPI driver to configure the device in a standard fashion. The presence of a _CID determines whether the ACPI Device Path node or the Expanded ACPI Device Path node should be used.

See Table below.

Table 10.61: ACPI_CRS to EFI Device Path Mapping

ACPI _CRS Item	EFI Device Path
PCI Root Bus	ACPI Device Path: _HID PNP0A03, _UID
Floppy	ACPI Device Path: _HID PNP0604, _UID drive select encoding 0-3
Keyboard	ACPI Device Path: _HID PNP0301, _UID 0
Serial Port	ACPI Device Path: _HID PNP0501, _UID Serial Port COM number 0-3
Parallel Port	ACPI Device Path: _HID PNP0401, _UID LPT number 0-3

Support of root PCI bridges requires special rules in the EFI Device Path. A root PCI bridge is a PCI device usually contained in a chipset that consumes a proprietary bus and produces a PCI bus. In typical desktop and mobile systems there is only one root PCI bridge. On larger server systems there are typically multiple root PCI bridges. The operation of root PCI bridges is not defined in any current PCI specification. A root PCI bridge should not be confused with a PCI to PCI bridge that both consumes and produces a PCI bus. The operation and configuration of PCI to PCI bridges is fully specified in current PCI specifications.

Root PCI bridges will use the plug and play ID of PNP0A03, This will be stored in the ACPI Device Path _HID field, or in the Expanded ACPI Device Path _CID field to match the ACPI name space. The _UID in the ACPI Device Path structure must match the _UID in the ACPI name space.

10.4.3 Rules with ACPI _ADR

If a device in the ACPI name space can be completely described by a _ADR object then it will map to an EFI ACPI, Hardware, or Message Device Path structure. A _ADR method implies a bus with a standard enumeration algorithm. If the ACPI device has a _ADR and a _CRS method, then it should also have a _HID method and follow the rules for using _HID. See the table below as it relates the ACPI _ADR bus definition to the EFI Device Path:

Table 10.62: ACPI _ADR to EFI Device Path Mapping

ACPI _ADR Bus	EFI Device Path
EISA	Not supported
Floppy Bus	ACPI Device Path: _HID PNP0604, _UID drive select encoding 0-3
IDE Controller	ATAPI Message Device Path: Maser/Slave : LUN
IDE Channel	ATAPI Message Device Path: Maser/Slave : LUN
PCI	PCI Hardware Device Path
PCMCIA	Not Supported
PC CARD	PC CARD Hardware Device Path
SMBus	Not Supported
SATA bus	SATA Messaging Device Path

10.4.4 Hardware vs. Messaging Device Path Rules

Hardware Device Paths are used to define paths on buses that have a standard enumeration algorithm and that relate directly to the coherency domain of the system. The coherency domain is defined as a global set of resources that is visible to at least one processor in the system. In a typical system this would include the processor memory space, IO space, and PCI configuration space.

Messaging Device Paths are used to define paths on buses that have a standard enumeration algorithm, but are not part of the global coherency domain of the system. SCSI and Fibre Channel are examples of this kind of bus. The Messaging Device Path can also be used to describe virtual connections over network-style devices. An example would be the TCP/IP address of an internet connection.

Thus Hardware Device Path is used if the bus produces resources that show up in the coherency resource domain of the system. A Message Device Path is used if the bus consumes resources from the coherency domain and produces resources out side the coherency domain of the system.

10.4.5 Media Device Path Rules

The Media Device Path is used to define the location of information on a medium. Hard Drives are subdivided into partitions by the MBR and a Media Device Path is used to define which partition is being used. A CD-ROM has boot partitions that are defined by the "El Torito" specification, and the Media Device Path is used to point to these partitions.

A *EFI_BLOCK_IO_PROTOCOL* is produced for both raw devices and partitions on devices. This allows the *EFI_SIMPLE_FILE_SYSTEM_PROTOCOL* protocol to not have to understand media formats. The EFI_BLOCK_IO_PROTOCOL for a partition contains the same Device Path as the parent EFI_BLOCK_IO_PROTOCOL for the raw device with the addition of a Media Device Path that defines which partition is being abstracted.

The Media Device Path is also used to define the location of a file in a file system. This Device Path is used to load files and to represent what file an image was loaded from.

10.4.6 Other Rules

The BIOS Boot Specification Device Path is not a typical Device Path. A Device Path containing the BIOS Boot Specification Device Path should only contain the required End Device Path structure and no other Device Path structures. The BIOS Boot Specification Device Path is only used to allow the EFI boot menus to boot a legacy operating system from legacy media.

The EFI Device Path can be extended in a compatible fashion by assigning your own vendor GUID to a Hardware, Messaging, or Media Device Path. This extension is guaranteed to never conflict with future extensions of this specification.

The EFI specification reserves all undefined Device Path types and subtypes. Extension is only permitted using a Vendor GUID Device Path entry.

10.5 Device Path Utilities Protocol

This section describes the EFI_DEVICE_PATH_UTILITIES_PROTOCOL, which aids in creating and manipulating device paths.

10.5.1 EFI_DEVICE_PATH_UTILITIES_PROTOCOL

Summary

Creates and manipulates device paths and device nodes.

GUID

```
// {0379BE4E-D706-437d-B037-EDB82FB772A4}
#define EFI_DEVICE_PATH_UTILITIES_PROTOCOL_GUID \
  {0x379be4e,0xd706,0x437d,\
    {0xb0,0x37,0xed,0xb8,0x2f,0xb7,0x72,0xa4 }}
```

Protocol Interface Structure

```
typedef struct _EFI_DEVICE_PATH_UTILITIES_PROTOCOL {
  EFI_DEVICE_PATH_UTILS_GET_DEVICE_PATH_SIZE    GetDevicePathSize;
  EFI_DEVICE_PATH_UTILS_DUP_DEVICE_PATH         DuplicateDevicePath;
  EFI_DEVICE_PATH_UTILS_APPEND_PATH             AppendDevicePath;
```

(continues on next page)

(continued from previous page)

```
  EFI_DEVICE_PATH_UTILS_APPEND_NODE             AppendDeviceNode;
  EFI_DEVICE_PATH_UTILS_APPEND_INSTANCE         AppendDevicePathInstance;
  EFI_DEVICE_PATH_UTILS_GET_NEXT_INSTANCE       GetNextDevicePathInstance;
  EFI_DEVICE_PATH_UTILS_IS_MULTI_INSTANCE       IsDevicePathMultiInstance;
  EFI_DEVICE_PATH_UTILS_CREATE_NODE             CreateDeviceNode;
}   EFI_DEVICE_PATH_UTILITIES_PROTOCOL;
```

Parameters

GetDevicePathSize
Returns the size of the specified device path, in bytes.

DuplicateDevicePath
Duplicates a device path structure.

AppendDeviceNode
Appends the device node to the specified device path.

AppendDevicePath
Appends the device path to the specified device path.

AppendDevicePathInstance
Appends a device path instance to another device path.

GetNextDevicePathInstance
Retrieves the next device path instance from a device path data structure.

IsDevicePathMultiInstance
Returns **TRUE** if this is a multi-instance device path.

CreateDeviceNode
Allocates memory for a device node with the specified type and sub-type.

Description

The EFI_DEVICE_PATH_UTILITIES_PROTOCOL provides common utilities for creating a manipulating device paths and device nodes.

10.5.2 EFI_DEVICE_PATH_UTILITIES_PROTOCOL.GetDevicePathSize()

Summary

Returns the size of the device path, in bytes.

Prototype

```
typedef
UINTN
(EFIAPI *EFI_DEVICE_PATH_UTILS_GET_DEVICE_PATH_SIZE) (
  IN CONST EFI_DEVICE_PATH_PROTOCOL          *DevicePath
  );
```

Parameters

DevicePath
Points to the start of the EFI device path.

Description

This function returns the size of the specified device path, in bytes, including the end-of-path tag. If *DevicePath* is NULL then zero is returned.

Related Definitions

EFI_DEVICE_PATH_PROTOCOL is defined in *EFI Device Path Protocol*.

10.5.3 EFI_DEVICE_PATH_UTILITIES_PROTOCOL.DuplicateDevicePath()

Summary

Create a duplicate of the specified path.

Prototype

```
typedef
EFI_DEVICE_PATH_PROTOCOL*
(EFIAPI *EFI_DEVICE_PATH_UTILS_DUP_DEVICE_PATH) (
  IN CONST EFI_DEVICE_PATH_PROTOCOL           *DevicePath
  );
```

Parameters

DevicePath
Points to the source device path.

Description

This function creates a duplicate of the specified device path. The memory is allocated from EFI boot services memory. It is the responsibility of the caller to free the memory allocated. If *DevicePath* is NULL then NULL will be returned and no memory will be allocated.

Related Definitions

EFI_DEVICE_PATH_PROTOCOL is defined in *EFI Device Path Protocol*.

Returns

This function returns a pointer to the duplicate device path or NULL if there was insufficient memory.

10.5.4 EFI_DEVICE_PATH_UTILITIES_PROTOCOL.AppendDevicePath()

Summary

Create a new path by appending the second device path to the first.

Prototype

```
typedef
EFI_DEVICE_PATH_PROTOCOL*
(EFIAPI *EFI_DEVICE_PATH_UTILS_APPEND_PATH) (
  IN CONST EFI_DEVICE_PATH_PROTOCOL      *Src1 ,
  IN CONST EFI_DEVICE_PATH_PROTOCOL      *Src2
  );
```

Parameters

Src1
Points to the first device path.

Src2

Points to the second device path.

Description

This function creates a new device path by appending a copy of the second device path to a copy of the first device path in a newly allocated buffer. Only the end-of-device-path device node from the second device path is retained. If *Src1* is NULL and *Src2* is non-NULL , then a duplicate of *Src2* is returned. If *Src1* is non-NULL and *Src2* is NULL, then a duplicate of *Src1* is returned. If *Src1* and *Src2* are both NULL, then a copy of an end-of-device-path is returned.

The memory is allocated from EFI boot services memory. It is the responsibility of the caller to free the memory allocated.

Related Definitions

EFI_DEVICE_PATH_PROTOCOL is defined in *EFI Device Path Protocol*.

Returns

This function returns a pointer to the newly created device path or NULL if memory could not be allocate.

10.5.5 EFI_DEVICE_PATH_UTILITIES_PROTOCOL.AppendDeviceNode()

Summary

Creates a new path by appending the device node to the device path.

Prototype

```
typedef
EFI_DEVICE_PATH_PROTOCOL*
(EFIAPI *EFI_DEVICE_PATH_UTILS_APPEND_NODE) (
IN CONST EFI_DEVICE_PATH_PROTOCOL         *DevicePath,
IN CONST EFI_DEVICE_PATH_PROTOCOL         *DeviceNode
);
```

Parameters

DevicePath

Points to the device path.

DeviceNode

Points to the device node.

Description

This function creates a new device path by appending a copy of the specified device node to a copy of the specified device path in an allocated buffer. The end-of-device-path device node is moved after the end of the appended device node. If *DeviceNode* is NULL then a copy of *DevicePath* is returned. If *DevicePath* is NULL then a copy of *DeviceNode* , followed by an end-of-device path device node is returned. If both *DeviceNode* and *DevicePath* are NULL then a copy of an end-of-device-path device node is returned.

The memory is allocated from EFI boot services memory. It is the responsibility of the caller to free the memory allocated.

Related Definitions

EFI_DEVICE_PATH_PROTOCOL is defined in *EFI Device Path Protocol*.

Returns

This function returns a pointer to the allocated device path, or NULL if there was insufficient memory.

10.5.6 EFI_DEVICE_PATH_UTILITIES_PROTOCOL.AppendDevicePathInstance()

Summary

Creates a new path by appending the specified device path instance to the specified device path.

Prototype

```
typedef
EFI_DEVICE_PATH_PROTOCOL*
(EFIAPI *EFI_DEVICE_PATH_UTILS_APPEND_INSTANCE) (
  IN CONST EFI_DEVICE_PATH_PROTOCOL       *DevicePath,
  IN CONST EFI_DEVICE_PATH_PROTOCOL       *DevicePathInstance
  );
```

Parameters

DevicePath
Points to the device path. If NULL, then ignored.

DevicePathInstance
Points to the device path instance

Description

This function creates a new device path by appending a copy of the specified device path instance to a copy of the specified device path in an allocated buffer. The end-of-device-path device node is moved after the end of the appended device node and a new end-of-device-path-instance node is inserted between. If *DevicePath* is NULL, then a copy if *DevicePathInstance* is returned instead.

The memory is allocated from EFI boot services memory. It is the responsibility of the caller to free the memory allocated.

Related Definitions

EFI_DEVICE_PATH_PROTOCOL is defined in *EFI Device Path Protocol*.

Returns

This function returns a pointer to the newly created device path or NULL if *DevicePathInstance* is NULL or there was insufficient memory.

10.5.7 EFI_DEVICE_PATH_UTILITIES_PROTOCOL.GetNextDevicePathInstance()

Summary

Creates a copy of the current device path instance and returns pointer to the next device path instance.

Prototype

```
typedef
EFI_DEVICE_PATH_PROTOCOL*
(EFIAPI *EFI_DEVICE_PATH_UTILS_GET_NEXT_INSTANCE) (
  IN OUT EFI_DEVICE_PATH_PROTOCOL         **DevicePathInstance,
  OUT UINTN                               *DevicePathInstanceSize* OPTIONAL
  );
```

Parameters

DevicePathInstance
On input, this holds the pointer to the current device path instance. On output, this holds the pointer to the next device path instance or NULL if there are no more device path instances in the device path.

DevicePathInstanceSize
On output, this holds the size of the device path instance, in bytes or zero, if *DevicePathInstance* is NULL. If NULL, then the instance size is not output.

Description

This function creates a copy of the current device path instance. It also updates *DevicePathInstance* to point to the next device path instance in the device path (or NULL if no more) and updates *DevicePathInstanceSize* to hold the size of the device path instance copy.

The memory is allocated from EFI boot services memory. It is the responsibility of the caller to free the memory allocated.

Related Definitions

EFI_DEVICE_PATH_PROTOCOL is defined in *EFI Device Path Protocol*.

Returns

This function returns a pointer to the copy of the current device path instance or NULL if *DevicePathInstance* was NULL on entry or there was insufficient memory.

10.5.8 EFI_DEVICE_PATH_UTILITIES_PROTOCOL.CreateDeviceNode()

Summary

Creates a device node

Prototype

```
typedef
EFI_DEVICE_PATH_PROTOCOL*
(EFIAPI *EFI_DEVICE_PATH_UTILS_CREATE_NODE) (
 IN UINT8               NodeType,
 IN UINT8               NodeSubType,
 IN UINT16              NodeLength
 );
```

Parameters

NodeType
NodeType is the device node type (EFI_DEVICE_PATH_PROTOCOL.Type) for the new device node.

NodeSubType
NodeSubType is the device node sub-type (EFI_DEVICE_PATH_PROTOCOL.SubType) for the new device node.

NodeLength
NodeLength is the length of the device node (EFI_DEVICE_PATH_PROTOCOL.Length) for the new device node.

Description

This function creates a new device node in a newly allocated buffer.

The memory is allocated from EFI boot services memory. It is the responsibility of the caller to free the memory allocated.

Related Definitions

EFI_DEVICE_PATH_PROTOCOL is defined in *EFI Device Path Protocol*.

Returns

This function returns a pointer to the created device node or NULL if *NodeLength* is less than the size of the header or there was insufficient memory.

10.5.9 EFI_DEVICE_PATH_UTILITIES_PROTOCOL.IsDevicePathMultiInstance()

Summary

Returns whether a device path is multi-instance.

Prototype

```
typedef
BOOLEAN
(EFIAPI *EFI_DEVICE_PATH_UTILS_IS_MULTI_INSTANCE) (
 IN CONST EFI_DEVICE_PATH_PROTOCOL      *DevicePath
 );
```

Parameters

DevicePath
Points to the device path. If NULL, then ignored.

Description

This function returns whether the specified device path has multiple path instances.

Related Definitions

EFI_DEVICE_PATH_PROTOCOL* is defined in *EFI Device Path Protocol*.

Returns

This function returns **TRUE** if the device path has more than one instance or **FALSE** if it is empty or contains only a single instance.

10.6 EFI Device Path Display Format Overview

This section describes the recommended conversion between an EFI Device Path Protocol and text. It also describes standard protocols for implementing these. The goals are:

- Standardized display format. This allows documentation and test tools to understand output coming from drivers provided by multiple vendors.
- Increase Readability. Device paths need to be read by people, so the format should be in a form which can be deciphered, maintaining as much as possible the industry standard means of presenting data. In this case, there are two forms, a display-only form and a parse-able form.
- Round-trip conversion from text to binary form and back to text without loss, if desired.

- Ease of command-line parsing. Since device paths can appear on the command-lines of UEFI applications executed from a shell, the conversion format should not prohibit basic command-line processing, either by the application or by a shell.

10.6.1 Design Discussion

The following subsections describe the design considerations for conversion to and from the EFI Device Path Protocol binary format and its corresponding text form.

10.6.1.1 Standardized Display Format

Before the UEFI 2.0, there was no standardized format for the conversion from the EFI Device Path protocol and text. Some de-facto standards arose, either as part of the standard implementation or in descriptive text in the EFI Device Driver Writer's Guide, although they didn't agree. The standardized format attempts to maintain at least the spirit of these earlier ideas.

10.6.1.2 Readability

Since these are conversions to text and, in many cases, users have to read and understand the text form of the EFI Device Path, it makes sense to make them as readable as reasonably possible. Several strategies are used to accomplish this:

- Creating simplified forms for well-known device paths. For example, a PCI root Bridge can be represented as Acpi(PNP0A03,0), but makes more sense as PciRoot(0). When converting from text to binary form, either form is accepted, but when converting from binary form to text, the latter is preferred.
- Omitting the conversion of fields which have empty or default values. By doing this, the average display length is greatly shortened, which improves readability.

10.6.1.3 Round-Trip Conversion

The conversions specified here guarantee at least that conversion to and from the binary representation of the EFI Device Path will be semantically identical.

Text-to-Binary-Conversion

Text $_1$ ð Binary $_1$ ð Text $_2$ ð Binary $_2$

In the above conversion, the process described in this section is applied to Text1, converting it to Binary1. Subsequently, Binary1 is converted to Text2. Finally, the Text2 is converted to Binary2. In these cases, Binary1 and Binary2 will always be identical. Text1 and Text2 may or may not be identical. This is the result of the fact that the text representation has, in some cases, more than one way of representing the same EFI Device Path node.

Binary to Text Conversion

Binary $_1$ ð Text $_1$ ð Binary $_2$ ðText $_2$

In the above conversion, the process described in this section is applied to Binary1, converting it to Text1. Subsequently, Text1 is converted to Binary2. Finally, Binary2 is converted to Text2. In these cases, Binary1 and Binary2 will always be identical and Text1 and Text2 will always be identical.

Another consideration in round-trip conversion is potential ambiguity in parsing. This happens when the text representation could be converted into more than type of device node, thus requiring information beyond that contained in the text representation in order to determine the correct conversion to apply. In the case of EFI Device Paths, this causes problems primarily with literal strings in the device path, such as those found in file names, volumes or directories.

For example, the file name Acpi(PNP0A03,0) might be a legal FAT32 file name. However, in parsing this, it is not clear whether it refers to an Acpi device node or a file name. Thus, it is ambiguous. In order to prevent ambiguity, certain characters may only be used for device node keywords and may not be used in file names or directories.

10.6.1.4 Command-Line Parsing

Applications written to this specification need to accept the text representation of EFI device paths as command-line parameters, possibly in the context of a command-prompt or shell. In order to do this, the text representation must follow simple guidelines concerning its format.

Command-line parsing generally involves three separate concepts: substitution, redirection and division.

In substitution, the invoker of the application modifies the actual contents of the command-line before it is passed to the application. For example:

```
copy *.xyz
```

In redirection, the invoker of the application gleans from the command line parameters which it uses to, for example, redirect or pipe input or output. For example:

```
echo This text is copied to a file >abc

dir | more
```

Finally, in division, the invoker or the application startup code divides the command-line up into individual arguments. The following line, for example, has (at least) three arguments, divided by whitespace:

```
copy /b file1.info file2.info
```

10.6.1.5 Text Representation Basics

This section describes the basic rules for the text representation of device nodes and device paths. The formal grammar describing appears later.

The text representation of a device path (or text device path) consists of one or more text device nodes, each preceded by a ‘/”’ or “' character. The behavior of a device path where the first node is not preceded by one of these characters is undefined. Some implementations may treat it as a relative path from a current working directory.

Spaces are not allowed at any point within the device path, except when contained in double quotes (“). The ‘|” (bar), ‘<” (less than) and ‘>” (greater than) characters are likewise reserved for use by the shell.

Device Path Text Representation

```
device-path:=\device-node
/device-node
\device-path device-node
/device-path device-node
```

There are two types of text device nodes : file-name/directory or canonical. Canonical text device nodes are prefixed by an option name consisting of only alphanumerical characters, followed by a parenthesis, followed by option-specific parameters separated by a ‘,’ (comma). File names and directories have no prefixes.

Text Device Node Names

```
device-node :=standard-device-node | file-name/directory
standard-device-node :=option-name(option-parameters)
file-name/directory := any character except '/''\''|''>''<'
```

The canonical device node can have zero or more option parameters between the parentheses. Multiple option parameters are separated by a comma. The meaning of the option parameters depends primarily on the option name, then the parameter-identifier (if present) and then the order of appearance in the parameter list. The parameter identifier allows the text representation to only contain the non-default option parameter value, even if it would normally appear fourth in the list of option parameters. Missing parameters do not require the comma unless needed as a placeholder to correctly increment the parameter count for a subsequent parameter.

Consider:

```
AcpiEx(HWP0002, PNP0A03,0)
```

Which could also be written:

```
AcpiEx(HWP0002,CID=PNP0A03) or

AcpiEx(HWP0002,PNP0A03)
```

Since CID and UID are optional parameters. Or consider:

```
Acpi(HWP0002,0)
```

Which could also be written:

```
Acpi(HWP0002)
```

Since UID is an optional parameter.

Device Node Option Names

```
option-name :=alphanumerical characters string
option-parameters :=option-parameter
option-parameters,option-parameter
option-parameter :=parameter-value
parameter-identifier=parameter-value
```

10.6.1.6 Text Device Node Reference

In each of the following table rows, a specific device node type and sub-type are given, along with the most general form of the text representation. Any parameters for the device node are listed in italics. In each case, the type is listed and along with it what is required or optional, and any default value, if applicable. On subsequent lines, alternate representations are listed. In general, these alternate representations are simplified by the assumption that one or more of the parameters is set to a specific value.

Parameter Types

This section describes the various types of option parameter values.

Table 10.63: EFI Device Path Option Parameter Values

GUID	An EFI GUID in standard format xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx. (See Appendix A)
Keyword	In some cases, one of a series of keywords must be listed.
Integer	Unless otherwise specified, this indicates an unsigned integer in the range of 0 to 2^32-1. The value is decimal, unless preceded by "0x" or "0X", in which case it is hexadecimal.
EISAID	A seven character text identifier in the format used by the ACPI specification. The first three characters must be alphabetic, either upper or lower case. The second four characters are hexadecimal digits, either numeric, upper case or lower case. Optionally, it can be the number 0.
String	Series of alphabetic, numeric and punctuation characters not including a right parenthesis ')', bar '
HexDump	Series of bytes, represented by two hexadecimal characters per byte. Unless otherwise indicated, the size is only limited by the length of the device node.
IPv4 Address	Series of four integer values (each between 0-255), separated by a '.' Optionally, followed by a ':' and an integer value between 0-65555. If the ':' is not present, then the port value is zero.
IPv6 Address	IPv6 Address is expressed in the format [address]:port. The 'address' is expressed in the way defined in RFC4291 Section 2.2. The ':port' after the [address] is optional. If present, the 'port' is an integer value between 0-65535 to represent the port number, or else, port number is zero.

Table 10.64: Device Node Table

Device Node Type/SubType/Other	**Description**
(when type is not recognized)	*Path* (*type, subtype, data*) The type is an integer from 0-255. The sub-type is an integer from 0-255. The data is a hex dump.
Type: 1 (Hardware Device Path) (when subtype is not recognized)	*HardwarePath* (subtype, data) The subtype is an integer from 0-255. The data is a hex dump.
Type: 1 (Hardware Device Path) SubType: 1 (PCI)	Pci(Device, Function) The Device is an integer from 0-31 and is required. The Function is an integer from 0-7 and is required.
Type: 1 (Hardware Device Path) SubType: 2 (PcPcard)	*PcCard* (Function) The Function is an integer from 0-255 and is required.

continues on next page

Table 10.64 – continued from previous page

Type: 1 (Hardware Device Path) SubType: 3 (Memory Mapped)	**MemoryMapped** (*EfiMemoryType,StartingAddress, EndingAddress*) The EfiMemoryType is a 32-bit integer and is required. The StartingAddress and EndingAddress are both 64-bit integers and are both required.
Type: 1 (Hardware Device Path) SubType: 4 (Vendor)	VenHw(Guid, Data) The Guid is a GUID and is required. The Data is a Hex Dump and is optional. The default value is zero bytes.
Type: 1 (Hardware Device Path) SubType: 5 (Controller)	Ctrl(Controller) Controller is an integer and is required.
Type: 1 (Hardware Device Path) SubType: 6 (BMC)	*BMC* (Type,Address) The Type is an integer from 0-255, and is required. The Address is an unsigned 64-bit integer, and is required.
Type: 2 (ACPI Device Path) (when subtype is not recognized)	AcpiPath(subtype, data) The subtype is an integer from 0-255. The data is a hex dump.
Type: 2 (ACPI Device Path) SubType: 1 (ACPI Device Path)	Acpi(HID,UID) The HID parameter is an EISAID and is required. The UID parameter is an integer and is optional. The default value is zero.
Type: 2 (ACPI Device Path) SubType: 1 (ACPI Device Path) HID=PNP0A03	PciRoot(UID) | The UID parameter is an integer. It is optional but required for display. The default value is zero.
Type: 2 (ACPI Device Path) SubType: 1 (ACPI Device Path) HID=PNP0A08	PcieRoot(UID) The UID parameter is an integer. It is optional but required for display. The default value is zero.

Type: 2 (ACPI Device Path) SubType: 1 (ACPI Device Path) HID=PNP0604	Floppy(UID) The UID parameter is an integer. It is optional for input but required for display. The default value is zero.
Type: 2 (ACPI Device Path) SubType: 1 (ACPI Device Path) HID=PNP0301	Keyboard(UID) The UID parameter is an integer. It is optional for input but required for display. The default value is 0.
Type: 2 (ACPI Device Path) SubType: 1 (ACPI Device Path) HID=PNP0501	Serial(UID) The UID parameter is an integer. It is optional for input but required for display. The default value is 0.
Type: 2 (ACPI Device Path) SubType: 1 (ACPI Device Path) HID=PNP0401	ParallelPort(UID) The UID parameter is an integer. It is optional for input but required for display. The default value is 0.
Type: 2 (ACPI Device Path) SubType: 2 (ACPI Expanded Device Path)	AcpiEx(HID,CID,UID,HIDSTR,CIDSTR,UIDSTR) AcpiEx(HID ,(CID Only) The HID parameter is an EISAID. The default value is 0. Either HID or HIDSTR must be present. The CID parameter is an EISAID. The default value is 0. Either CID must be 0 or CIDSTR must be empty. The UID parameter is an integer. The default value is 0. Either UID must be 0 or UIDSTR must be empty. The HIDSTR is a string. The default value is the empty string. Either HID or HIDSTR must be present. The CIDSTR is a string. The default value is an empty string. Either CID must be 0 or CIDSTR must be empty. The UIDSTR is a string. The default value is an empty string. Either UID must be 0 or UIDSTR must be empty.

Type: 3 (Messaging Device Path) SubType: 10 (Serial Attached SCSI) Vendor GUID: d48 7ddb4-008b-11d9-afdc-001083ffca4d	**SAS** (*Address, LUN, RTP, SASSATA, Location, Connect, DriveBay, Reserved*) The Address is a 64-bit unsigned integer representing the SAS Address and is required. The LUN is a 64-bit unsigned integer representing the Logical Unit Number and is optional. The default value is 0. The RTP is a 16-bit unsigned integer representing the Relative Target Port and is optional. The default value is 0. The SASSATA is a keyword SAS or SATA or NoTopology or an unsigned 16-bit integer and is optional. The default is NoTopology. If NoTopology or an integer are specified, then Location, Connect and DriveBay are prohibited. If SAS or SATA is specified, then Location and Connect are required, but DriveBay is optional. If an integer is specified, then the topology information is filled with the integer value. The Location is an integer between 0 and 1 or else the keyword Internal (0) or External (1) and is optional. If SASSATA is an integer or NoToplogy, it is prohibited. The default value is 0. The Connect is an integer between 0 and 3 or else the keyword Direct (0) or Expanded (1) and is optional. If SASSATA is an integer or NoTopology, it is prohibited. The default value is 0. The DriveBay is an integer between 1 and 256 and is optional unless SASSATA is an integer or NoTopology, in which case it is prohibited. The Reserved field is an integer and is optional. The default value is 0.
Type: 3 (Messaging Device Path) SubType: 10 (Vendor) GUID=EFI_DEBUGPORT_PROTOCOL_GUID	DebugPort()
Type: 3 (Messaging Device Path) SubType: 11 (MAC Address)	MAC(MacAddr, IfType) The MacAddr is a Hex Dump and is required. If IfType is 0 or 1, then the MacAddr must be exactly six bytes. The IfType is an integer from 0-255 and is optional. The default is zero.

Type: 3 (Messaging Device Path) SubType: 12 (IPv4)	IPv4(RemoteIp, Protocol, Type, LocalIp, GatewayIPAddress, SubnetMask) IPv4(RemoteIp) (Display Only) The RemoteIp is an IP Address and is required. The Protocol is an integer between 0 and 255 or else the keyword UDP (17) or TCP (6). The default value is UDP. The Type is a keyword, either Static (1) or DHCP (0). It is optional. The default value is DHCP. The LocalIp is an IP Address and is optional. The default value is all zeroes. The GatewayIPAddress is an IP Address and is optional. The default value is all zeroes. The SubnetMask is an IP Address and is optional. The default value is all zeroes.
Type: 3 (Messaging Device Path) SubType: 13 (IPv6)	IPv6(RemoteIp, Protocol, IPAddressOrigin, LocalIp, GatewayIPAddress, SubnetMask) IPv6(RemoteIp) (Display Only) The RemoteIp is an IPv6 Address and is required. The Protocol is an integer between 0 and 255 or else the keyword UDP (17) or TCP (6). The default value is UDP. The IPAddressOrigin is a keyword, could be Static (0), StatelessAutoConfigure (1), or StatefulAutoConfigure (2). The LocalIp is the IPv6 Address and is optional. The default value is all zeroes. The GatewayIPAddress is an IP Address. The PrefixLength is the prefix length of the Local IPv6 Address. The GatewayIPAddress is the IPv6 Address of the Gateway.
Type: 3 (Messaging Device Path) SubType: 14 (UART)	Uart(Baud, DataBits, Parity, StopBits) The Baud is a 64-bit integer and is optional. The default value is 115200. The DataBits is an integer from 0 to 255 and is optional. The default value is 8. The Parity is either an integer from 0-255 or else a keyword and should be D (0), N (1), E (2), O (3), M (4) or S (5). It is optional. The default value is 0. The StopBits is a either an integer from 0-255 or else a keyword and should be D (0), 1 (1), 1.5 (2), 2 (3). It is optional. The default value is 0. *Parity* and *StopBits* can either be two integers or two keywords. Mixing formats is prohibited.

Table 10.64 – continued from previous page

Type: 3 (Messaging Device Path) SubType: 16 (USB WWID Class)	UsbWwi d(VID,PID,InterfaceNumber,"WWID") The VID is an integer between 0 and 65535 and is required. The PID is an integer between 0 and 65535 and is required. The InterfaceNumber is an integer between 0 and 255 and is required. The WWID is a string and is required.
Type: 3 (Messaging Device Path) SubType: 17 (Logical Unit Class)	Unit(LUN) The LUN is an integer and is required.
Type: 3 (Messaging Device Path) SubType: 18 (SATA)	Sata(HPN, PMPN, LUN) The HPN is an integer between 0 and 65534 and is required. The PMPN is an integer between 0 and 65535 and is optional. If not provided, the default is 0xFFFF, which implies no port multiplier. The LUN is a 16-bit integer. It is required. Note that LUN is applicable to ATAPI devices only, and most ATAPI devices assume LUN=0
Type: 3 (Messaging Device Path) SubType: 19 (iSCSI)	iSCSI(TargetName, PortalGroup, LUN, HeaderDigest, DataDigest, Authentication, Protocol) The TargetName is a string and is required. PortalGroup is an unsigned 16-bit integer and is required. The LUN is an 8 byte array that is displayed in hexadecimal format with byte 0 first (i.e., on the left) and byte 7 last (i.e, on the right), and is required. The HeaderDigest is a keyword None or CRC32C is optional. The default is None. The DataDigest is a keyword None or CRC32C is optional. The default is None. The Authentication is a keyword None or CHAP_BI or CHAP_UNI and optional. The default is None. The Protocol defines the network protocol used by iSCSI and is optional. The default is TCP.
Type: 3 (Messaging Device Path) SubType: 20 (VLAN)	*Vlan* (VlanId)

Table 10.64 – continued from previous page

Type: 3 (Messaging Device Path) SubType: 22 (Serial Attached SCSI Ex)	*SasEx (Address, LUN, RTP, SASSATA, Location, Connect, DriveBay)* The *Address* is an 8 byte array that is displayed in hexadecimal format with byte 0 first (i.e., on the left) and byte 7 last (i.e., on the right), and is required. The *LUN* is an 8 byte array that is displayed in hexadecimal format with byte 0 first (i.e., on the left) and byte 7 last (i.e., on the right), and is optional. The default value is 0. The *RTP* is a 16-bit unsigned integer representing the Relative Target Port and is optional. The default value is 0. The *SASSATA* is a keyword *SA* S or *SATA* or *NoTopology* or an unsigned 16-bit integer and is optional. The default is NoTopology. If NoTopology or an integer are specified, then *Location* , *Connect* and *DriveBay* are prohibited. If *SAS* or *SATA* is specified, then *Location* and Connect are required, but *DriveBay* is optional. If an integer is specified, then the topology information is filled with the integer value. The *Location* is an integer between 0 and 1 or else the keyword *Internal* (0) or *External* (1) and is optional. If *SASSATA* is an integer or *NoToplogy* , it is prohibited. The default value is 0. The *Connect* is an integer between 0 and 3 or else the keyword Direct (0) or Expanded (1) and is optional. If *SASSATA* is an integer or *NoTopology* , it is prohibited. The default value is 0. The *DriveBay* is an integer between 1 and 256 and is optional unless *SASSATA* is an integer or *NoTopology* , in which case it is prohibited.
Type: 3 (Messaging Device Path) SubType: 23 (NVM Express Namespace)	NVMe(NSID,EUI) The NSID is a namespace identifier that is displayed in hexadecimal format with an integer value between 0 and 0xFFFFFFFF. The EUI is the IEEE Extended Unique Identifier (EUI-64) that is displayed in hexadecimal format represented as a set of octets separated by dashes (hexadecimal notation), e.g., FF-FF-FF-FF-FF-FF-FF-FF.
Type: 3 (Messaging Device Path) SubType: 24 (URI)	Uri(*Uri*) The *Uri* is optional.
Type: 3 (Messaging Device Path) SubType: 25 (Universal Flash Storage)	*UFS* (*PUN,LUN*) The *PUN* is 0 for current UFS2.0 spec. For future UFS specs which support multiple devices on a UFS port, it would reflect the device ID on the UFS port. The *LUN* is 0-7 for common LUNs or 81h, D0h, B0h and C4h for well-known LUNs supported by UFS.
Type: 3 (Messaging Device Path) SubType: 26 (SD)	*SD* (*Slot Number*) *SlotNumber* is an integer. It is optional and has a default value of 0.

Table 10.64 – continued from previous page

Type: 4 (Media Device Path) SubType: 9 (RAM Disk) Disk Type GUID= EFI_PERSISTENT _VIRTUAL_CD_GUID	*PersistentVirtualCD* (*StartingAddress* , *EndingAddress* , *DiskInstance*) The *StartingAddress* and *EndingAddress* are both 64-bit integers and are both required. The *DiskInstance* is a 16-bit integer and is optional. The default value is 0.
Type: 5 (Media Device Path) (when subtype is not recognized)	BbsPath(subtype, data) The subtype is an integer from 0-255. The data is a hex dump.
Type: 5 (BIOS Boot Specification Device Path) SubType: 1 (BBS 1.01)	BBS(Type,Id,Flags) BBS(Type, Id) (Display Only) The Type is an integer from 0-65535 or else one of the following keywords: Floppy (1), HD (2), CDROM (3), PCMCIA (4), USB (5), Network (6). It is required. The Id is a string and is required. The Flags are an integer and are optional. The default value is 0.

10.6.2 Device Path to Text Protocol

10.6.2.1 EFI_DEVICE_PATH_TO_TEXT_PROTOCOL

Summary

Convert device nodes and paths to text.

GUID

```
#define EFI_DEVICE_PATH_TO_TEXT_PROTOCOL_GUID \
  {0x8b843e20,0x8132,0x4852,\
    {0x90,0xcc,0x55,0x1a,0x4e,0x4a,0x7f,0x1c}}
```

Protocol Interface Structure

```
typedef struct _EFI_DEVICE_PATH_TO_TEXT_PROTOCOL {
  EFI_DEVICE_PATH_TO_TEXT_NODE        ConvertDeviceNodeToText;
  EFI_DEVICE_PATH_TO_TEXT_PATH        ConvertDevicePathToText;
}  EFI_DEVICE_PATH_TO_TEXT_PROTOCOL;
```

Parameters

ConvertDeviceNodeToText
Converts a device node to text.

ConvertDevicePathToText
Converts a device path to text.

Description

The EFI_DEVICE_PATH_TO_TEXT_PROTOCOL provides common utility functions for converting device nodes and device paths to a text representation.

10.6.3 EFI_DEVICE_PATH_TO_TEXT_PROTOCOL.ConvertDeviceNodeToText()

Summary

Convert a device node to its text representation.

Prototype

```
typedef
CHAR16*
(EFIAPI *EFI_DEVICE_PATH_TO_TEXT_NODE) (
  IN CONST EFI_DEVICE_PATH_PROTOCOL*    DeviceNode,
  IN BOOLEAN                    DisplayOnly,
  IN BOOLEAN                    AllowShortcuts
  );
```

Parameters

DeviceNode
Points to the device node to be converted.

DisplayOnly
If *DisplayOnly* is **TRUE**, then the shorter text representation of the display node is used, where applicable. If *DisplayOnly* is **FALSE**, then the longer text representation of the display node is used.

AllowShortcuts
If *AllowShortcuts* is **TRUE**, then the shortcut forms of text representation for a device node can be used, where applicable.

Description

The ConvertDeviceNodeToText function converts a device node to its text representation and copies it into a newly allocated buffer.

The *DisplayOnly* parameter controls whether the longer (parseable) or shorter (display-only) form of the conversion is used.

The *AllowShortcuts* is **FALSE**, then the shortcut forms of text representation for a device node cannot be used. A shortcut form is one which uses information other than the type or subtype.

The memory is allocated from EFI boot services memory. It is the responsibility of the caller to free the memory allocated.

Related Definitions

EFI_DEVICE_PATH_PROTOCOL is defined in *EFI Device Path Protocol*

Returns

This function returns the pointer to the allocated text representation of the device node data or else NULL if *DeviceNode* was NULL or there was insufficient memory.

10.6.4 EFI_DEVICE_PATH_TO_TEXT_PROTOCOL.ConvertDevicePathToText()

Summary

Convert a device path to its text representation.

Prototype

```
typedef
CHAR16*
(EFIAPI *EFI_DEVICE_PATH_TO_TEXT_PATH) (
  IN CONST EFI_DEVICE_PATH_PROTOCOL       *DevicePath,
  IN BOOLEAN                              DisplayOnly,
  IN BOOLEAN                              AllowShortcuts
  );
```

Parameters

DeviceNode
Points to the device path to be converted.

DisplayOnly
If *DisplayOnly* is **TRUE**, then the shorter text representation of the display node is used, where applicable. If *DisplayOnly* is **FALSE**, then the longer text representation of the display node is used.

AllowShortcuts
The *AllowShortcuts* is **FALSE**, then the shortcut forms of text representation for a device node cannot be used.

Description

This function converts a device path into its text representation and copies it into an allocated buffer.

The *DisplayOnly* parameter controls whether the longer (parseable) or shorter (display-only) form of the conversion is used.

The *AllowShortcuts* is **FALSE**, then the shortcut forms of text representation for a device node cannot be used. A shortcut form is one which uses information other than the type or subtype.

The memory is allocated from EFI boot services memory. It is the responsibility of the caller to free the memory allocated.

Related Definitions

EFI_DEVICE_PATH_PROTOCOL* is defined in *EFI Device Path Protocol*.

Returns

This function returns a pointer to the allocated text representation of the device node or NULL if *DevicePath* was NULL or there was insufficient memory.

10.6.5 Device Path from Text Protocol

10.6.5.1 EFI_DEVICE_PATH_FROM_TEXT_PROTOCOL

Summary

Convert text to device paths and device nodes.

GUID

```
#define EFI_DEVICE_PATH_FROM_TEXT_PROTOCOL_GUID \
  {0x5c99a21,0xc70f,0x4ad2,\
    {0x8a,0x5f,0x35,0xdf,0x33,0x43,0xf5, 0x1e}}
```

Protocol Interface Structure

```
typedef struct _EFI_DEVICE_PATH_FROM_TEXT_PROTOCOL {
EFI_DEVICE_PATH_FROM_TEXT_NODE           ConvertTextToDevicNode;
EFI_DEVICE_PATH_FROM_TEXT_PATH           ConvertTextToDevicPath;
} EFI_DEVICE_PATH_FROM_TEXT_PROTOCOL;
```

Parameters

ConvertTextToDeviceNode
Converts text to a device node.

ConvertTextToDevicePath
Converts text to a device path.

Description

The *EFI_DEVICE_PATH_FROM_TEXT_PROTOCOL* provides common utilities for converting text to device paths and device nodes.

10.6.5.2 EFI_DEVICE_PATH_FROM_TEXT_PROTOCOL.ConvertTextToDeviceNode()

Summary

Convert text to the binary representation of a device node.

Prototype

```
typedef
EFI_DEVICE_PATH_PROTOCOL*
(EFIAPI *EFI_DEVICE_PATH_FROM_TEXT_NODE) (
  IN CONST CHAR16*          TextDeviceNode
  );
```

Parameters

TextDeviceNode
TextDeviceNode points to the text representation of a device node. Conversion starts with the first character and continues until the first non-device node character.

Description

This function converts text to its binary device node representation and copies it into an allocated buffer.

The memory is allocated from EFI boot services memory. It is the responsibility of the caller to free the memory allocated.

Related Definitions

EFI_DEVICE_PATH_PROTOCOL is defined in *EFI Device Path Protocol* .

Returns

This function returns a pointer to the EFI device node or NULL if *TextDeviceNode* is NULL or there was insufficient memory.

10.6.5.3 EFI_DEVICE_PATH_FROM_TEXT_PROTOCOL.ConvertTextToDevicePath(

Summary

Convert a text to its binary device path representation.

Prototype

```
typedef
EFI_DEVICE_PATH_PROTOCOL*
(EFIAPI *EFI_DEVICE_PATH_FROM_TEXT_PATH) (
  IN CONST CHAR16*                     TextDevicePath
  );
```

Parameters

TextDevicePath
TextDevicePath points to the text representation of a device path. Conversion starts with the first character and continues until the first non-device path character.

Description

This function converts text to its binary device path representation and copies it into an allocated buffer.

The memory is allocated from EFI boot services memory. It is the responsibility of the caller to free the memory allocated.

Related Definitions

EFI_DEVICE_PATH_PROTOCOL is defined in *EFI Device Path Protocol* .

Returns

This function returns a pointer to the allocated device path or NULL if *TextDevicePath* is NULL or there was insufficient memory.

CHAPTER

ELEVEN

PROTOCOLS — UEFI DRIVER MODEL

EFI drivers that follow the UEFI Driver Model are not allowed to search for controllers to manage. When a specific controller is needed, the EFI boot service *EFI_BOOT_SERVICES.ConnectController()* is used along with the *EFI Driver Binding Protocol* services to identify the best drivers for a controller. Once *ConnectController()* has identified the best drivers for a controller, the start service in the *EFI_DRIVER_BINDING_PROTOCOL* is used by *ConnectController()* to start each driver on the controller. Once a controller is no longer needed, it can be released with the EFI boot service *EFI_BOOT_SERVICES.DisconnectController()* . *DisconnectController()* calls the stop service in each *EFI_DRIVER_BINDING_PROTOCOL* to stop the controller.

The driver initialization routine of an UEFI driver is not allowed to touch any device hardware. Instead, it just installs an instance of the *EFI_DRIVER_BINDING_PROTOCOL* on the ImageHandle of the UEFI driver. The test to determine if a driver supports a given controller must be performed in as little time as possible without causing any side effects on any of the controllers it is testing. As a result, most of the controller initialization code is present in the start and stop services of the *EFI_DRIVER_BINDING_PROTOCOL*.

11.1 EFI Driver Binding Protocol

This section provides a detailed description of the *EFI_DRIVER_BINDING_PROTOCOL* . This protocol is produced by every driver that follows the UEFI Driver Model, and it is the central component that allows drivers and controllers to be managed. It provides a service to test if a specific controller is supported by a driver, a service to start managing a controller, and a service to stop managing a controller. These services apply equally to drivers for both bus controllers and device controllers.

11.1.1 EFI_DRIVER_BINDING_PROTOCOL

Summary

Provides the services required to determine if a driver supports a given controller. If a controller is supported, then it also provides routines to start and stop the controller.

GUID

```
#define EFI_DRIVER_BINDING_PROTOCOL_GUID \
 {0x18A031AB,0xB443,0x4D1A,\
  {0xA5,0xC0,0x0C,0x09,0x26,0x1E,0x9F,0x71}}
```

Protocol Interface Structure

```
typedef struct \_EFI_DRIVER_BINDING_PROTOCOL {
 EFI_DRIVER_BINDING_PROTOCOL_SUPPORTED        Supported;
 EFI_DRIVER_BINDING_PROTOCOL_START            Start;
```

(continues on next page)

(continued from previous page)

```
 EFI_DRIVER_BINDING_PROTOCOL_STOP             Stop;
 UINT32                                       Version;
 EFI__HANDLE                                  ImageHandle;
 EFI_HANDLE                                   DriverBindingHandle;
} EFI_DRIVER_BINDING_PROTOCOL;
```

Parameters

Supported

Tests to see if this driver supports a given controller. This service is called by the EFI boot service *EFI_BOOT_SERVICES.ConnectController()* . In order to make drivers as small as possible, there are a few calling restrictions for this service. ConnectController() must follow these calling restrictions. If any other agent wishes to call *EFI_DRIVER_BINDING_PROTOCOL.Supported()* it must also follow these calling restrictions. See the Supported() function description.

Start

Starts a controller using this driver. This service is called by the EFI boot service ConnectController(). In order to make drivers as small as possible, there are a few calling restrictions for this service. ConnectController() must follow these calling restrictions. If any other agent wishes to call *EFI_DRIVER_BINDING_PROTOCOL.Start()* it must also follow these calling restrictions. See the Start() function description.

Stop

Stops a controller using this driver. This service is called by the EFI boot service *EFI_BOOT_SERVICES.DisconnectController()* . In order to make drivers as small as possible, there are a few calling restrictions for this service. DisconnectController() must follow these calling restrictions. If any other agent wishes to call *EFI_DRIVER_BINDING_PROTOCOL.Stop()* it must also follow these calling restrictions. See the Stop() function description.

Version

The version number of the UEFI driver that produced the EFI_DRIVER_BINDING_PROTOCOL. This field is used by the EFI boot service ConnectController() to determine the order that driver's Supported() service will be used when a controller needs to be started. EFI Driver Binding Protocol instances with higher Version values will be used before ones with lower Version values. The Version values of 0x0-0x0f and 0xfffffff0-0xffffffff are reserved for platform/OEM specific drivers. The Version values of 0x10-0xffffffef are reserved for IHV-developed drivers.

ImageHandle

The image handle of the UEFI driver that produced this instance of the EFI_DRIVER_BINDING_PROTOCOL.

DriverBindingHandle

The handle on which this instance of the EFI_DRIVER_BINDING_PROTOCOL is installed. In most cases, this is the same handle as ImageHandle. However, for UEFI drivers that produce more than one instance of the EFI_DRIVER_BINDING_PROTOCOL, this value may not be the same as ImageHandle.

Description

The *EFI_DRIVER_BINDING_PROTOCOL* provides a service to determine if a driver supports a given controller. If a controller is supported, then it also provides services to start and stop the controller. All UEFI drivers are required to be reentrant so they can manage one or more controllers. This requires that drivers not use global variables to store device context. Instead, they must allocate a separate context structure per controller that the driver is managing. Bus drivers must support starting and stopping the same bus multiple times, and they must also support starting and stopping all of their children, or just a subset of their children.

11.1.2 EFI_DRIVER_BINDING_PROTOCOL.Supported()

Summary

Tests to see if this driver supports a given controller. If a child device is provided, it further tests to see if this driver supports creating a handle for the specified child device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_DRIVER_BINDING_PROTOCOL_SUPPORTED) (
 IN EFI_DRIVER_BINDING_PROTOCOL            *This,
 IN EFI_HANDLE                             ControllerHandle,
 IN EFI_DEVICE_PATH_PROTOCOL               *RemainingDevicePath OPTIONAL
 );
```

Parameters

This
A pointer to the *EFI Driver Binding Protocol* instance.

ControllerHandle
The handle of the controller to test. This handle must support a protocol interface that supplies an I/O abstraction to the driver. Sometimes just the presence of this I/O abstraction is enough for the driver to determine if it supports ControllerHandle. Sometimes, the driver may use the services of the I/O abstraction to determine if this driver supports ControllerHandle.

RemainingDevicePath
A pointer to the remaining portion of a device path. For bus drivers, if this parameter is not NULL, then the bus driver must determine if the bus controller specified by ControllerHandle and the child controller specified by RemainingDevicePath are both supported by this bus driver.

Description

This function checks to see if the driver specified by This supports the device specified by *ControllerHandle*. Drivers will typically use the device path attached to ControllerHandle and/or the services from the bus I/O abstraction attached to *ControllerHandle* to determine if the driver supports *ControllerHandle*. This function may be called many times during platform initialization. In order to reduce boot times, the tests performed by this function must be very small, and take as little time as possible to execute. This function must not change the state of any hardware devices, and this function must be aware that the device specified by *ControllerHandle* may already be managed by the same driver or a different driver. This function must match its calls to *EFI_BOOT_SERVICES.AllocatePages()* with *EFI_BOOT_SERVICES.FreePages()* , *EFI_BOOT_SERVICES.AllocatePool()* with *EFI_BOOT_SERVICES.FreePool()* , and *EFI_BOOT_SERVICES.OpenProtocol()* with *EFI_BOOT_SERVICES.CloseProtocol()* . Since ControllerHandle may have been previously started by the same driver, if a protocol is already in the opened state, then it must not be closed with *CloseProtocol()* . This is required to guarantee the state of ControllerHandle is not modified by this function.

If any of the protocol interfaces on the device specified by ControllerHandle that are required by the driver specified by This are already open for exclusive access by a different driver or application, then *EFI_ACCESS_DENIED* is returned.

If any of the protocol interfaces on the device specified by ControllerHandle that are required by the driver specified by This are already opened by the same driver, then *EFI_ALREADY_STARTED* is returned. However, if the driver specified by *This* is a bus driver, then it is not an error, and the bus driver should continue with its test of *ControllerHandle* and *RemainingDevicePath* . This allows a bus driver to create one child handle on the first call to *EFI_DRIVER_BINDING_PROTOCOL.Supported()* and *EFI_DRIVER_BINDING_PROTOCOL.Start()*, and create additional child handles on additional calls to *Supported()* and *Start()* .This also allows a bus driver to create no child handle on the first call to *Supported()* and *Start()* by specifying an End of Device Path Node *RemainingDevicePath* , and create additional child handles on additional calls to *Supported()* and *Start()* .

If ControllerHandle is not supported by This, then *EFI_UNSUPPORTED* is returned.

If This is a bus driver that creates child handles with an *EFI Device Path Protocol* , then ControllerHandle must support the *EFI_DEVICE_PATH_PROTOCOL* . If it does not, then *EFI_UNSUPPORTED* is returned.

If ControllerHandle is supported by This, and This is a device driver, then *EFI_SUCCESS* is returned.

If ControllerHandle is supported by This, and This is a bus driver, and RemainingDevicePath is *NULL* or the first Device Path Node is the End of Device Path Node, then *EFI_SUCCESS* is returned.

If ControllerHandle is supported by This, and This is a bus driver, and RemainingDevicePath is not *NULL* , then RemainingDevicePath must be analyzed. If the first node of *RemainingDevicePath* is the End of Device Path Node or an EFI Device Path node that the bus driver recognizes and supports, then *EFI_SUCCESS* is returned. Otherwise, *EFI_UNSUPPORTED* is returned.

The *Supported()* function is designed to be invoked from the EFI boot service *EFI_BOOT_SERVICES.ConnectController()* . As a result, much of the error checking on the parameters to *Supported()* has been moved into this common boot service. It is legal to call *Supported()* from other locations, but the following calling restrictions must be followed or the system behavior will not be deterministic.

ControllerHandle must be a valid *EFI_HANDLE* . If RemainingDevicePath is not *NULL* , then it must be a pointer to a naturally aligned *EFI_DEVICE_PATH_PROTOCOL* .

Status Codes Returned

EFI_SUCCESS	The device specified by ControllerHandle and RemainingDevicePath is supported by the driver specified by This.
EFI_ALREADY_STARTED	The device specified by ControllerHandle and RemainingDevicePath is already being managed by the driver specified by This.
EFI_ACCESS_DENIED	The device specified by ControllerHandle and RemainingDevicePath is already being managed by a different driver or an application that requires exclusive access.
EFI_UNSUPPORTED	The device specified by ControllerHandle and RemainingDevicePath is not supported by the driver specified by This.

Examples

```
extern EFI_GUID                gEfiDriverBindingProtocolGuid;
EFI_HANDLE                     DriverImageHandle;
EFI_HANDLE                     ControllerHandle;
EFI_DRIVER_BINDING_PROTOCOL    *DriverBinding;
EFI_DEVICE_PATH_PROTOCOL       *RemainingDevicePath;

//
// Use the DriverImageHandle to get the Driver Binding protocol instance
//
Status = gBS->OpenProtocol (
         DriverImageHandle,
         &gEfiDriverBindingProtocolGuid,
         &DriverBinding,
         DriverImageHandle,
         NULL,
         EFI_OPEN_PROTOCOL_GET_PROTOCOL
         );
```

(continues on next page)

(continued from previous page)

```
if (EFI_ERROR (Status)) {
  return Status;
}

//
// EXAMPLE #1
//
// Use the Driver Binding Protocol instance to test to see if the
// driver specified by DriverImageHandle supports the controller
// specified by ControllerHandle
//
Status = DriverBinding->Supported (
            DriverBinding,
            ControllerHandle,
            NULL
            );
return Status;

//
// EXAMPLE #2
//
// The RemainingDevicePath parameter can be used to initialize only
// the minimum devices required to boot. For example, maybe we only
// want to initialize 1 hard disk on a SCSI channel. If DriverImageHandle
// is a SCSI Bus Driver, and ControllerHandle is a SCSI    Controller, and
// we only want to create a child handle for PUN=3 and LUN=0, then the
// RemainingDevicePath would be SCSI(3,0)/END. The following  example
// would return EFI_SUCCESS if the SCSI driver supports creating the
// child handle for PUN=3, LUN=0. Otherwise it would return an error.
//
Status = DriverBinding->Supported (
               DriverBinding,
               ControllerHandle,
               RemainingDevicePath
               );
return Status;
```

Pseudo Code

Listed below are the algorithms for the *EFI_DRIVER_BINDING_PROTOCOL.Supported()* function for three different types of drivers. How the *EFI_DRIVER_BINDING_PROTOCOL.Start()* function of a driver is implemented can affect how the *Supported()* function is implemented. All of the services in the *EFI Driver Binding Protocol* need to work together to make sure that all resources opened or allocated in *Supported()* and *Start()* are released in *EFI_DRIVER_BINDING_PROTOCOL.Stop()*

The first algorithm is a simple device driver that does not create any additional handles. It only attaches one or more protocols to an existing handle. The second is a bus driver that always creates all of its child handles on the first call to *Start()* . The third is a more advanced bus driver that can either create one child handles at a time on successive calls to *Start()* , or it can create all of its child handles or all of the remaining child handles in a single call to *Start()* .

Device Driver:

1. Ignore the parameter *RemainingDevicePath*.
2. Open all required protocols with *EFI_BOOT_SERVICES.OpenProtocol()* . A standard driver should use an

Attribute of *EFI_OPEN_PROTOCOL_BY_DRIVER* . If this driver needs exclusive access to a protocol interface, and it requires any drivers that may be using the protocol interface to disconnect, then the driver should use an *Attribute* of *EFI_OPEN_PROTOCOL_BY_DRIVER | EFI_OPEN_PROTOCOL_EXCLUSIVE* .

3. If any of the calls to *OpenProtocol()* in (2) returned an error, then close all of the protocols opened in (2) with *EFI_BOOT_SERVICES.CloseProtocol()* , and return the status code from the call to *OpenProtocol()* that returned an error.
4. Use the protocol instances opened in (2) to test to see if this driver supports the controller. Sometimes, just the presence of the protocols is enough of a test. Other times, the services of the protocols opened in (2) are used to further check the identity of the controller. If any of these tests fails, then close all the protocols opened in (2) with *CloseProtocol()* and return *EFI_UNSUPPORTED* .
5. Close all protocols opened in (2) with *CloseProtocol()* .
6. Return *EFI_SUCCESS* .

Bus Driver that creates all of its child handles on the first call to Start():

1. Check the contents of the first Device Path Node of *RemainingDevicePath* to make sure it is the End of Device Path Node or a legal Device Path Node for this bus driver's children. If it is not, then return *EFI_UNSUPPORTED* .
2. Open all required protocols with *EFI_BOOT_SERVICES.OpenProtocol()* . A standard driver should use an *Attribute* of *EFI_OPEN_PROTOCOL_BY_DRIVER* . If this driver needs exclusive access to a protocol interface, and it requires any drivers that may be using the protocol interface to disconnect, then the driver should use an *Attribute* of *EFI_OPEN_PROTOCOL_BY_DRIVER | EFI_OPEN_PROTOCOL_EXCLUSIVE*.
3. If any of the calls to *OpenProtocol()* in (2) returned an error, then close all of the protocols opened in (2) with *EFI_BOOT_SERVICES.CloseProtocol()* , and return the status code from the call to *OpenProtocol()* that returned an error.
4. Use the protocol instances opened in (2) to test to see if this driver supports the controller. Sometimes, just the presence of the protocols is enough of a test. Other times, the services of the protocols opened in (2) are used to further check the identity of the controller. If any of these tests fails, then close all the protocols opened in (2) with *CloseProtocol()* and return *EFI_UNSUPPORTED* . #. Close all protocols opened in (2) with *CloseProtocol()* .
5. Return *EFI_SUCCESS* .

Bus Driver that is able to create all or one of its child handles on each call to Start():

1. Check the contents of the first Device Path Node of *RemainingDevicePath* to make sure it is the End of Device Path Node or a legal Device Path Node for this bus driver's children. If it is not, then return *EFI_UNSUPPORTED* .
2. Open all required protocols with *OpenProtocol()* . A standard driver should use an *Attribute* of *EFI_OPEN_PROTOCOL_BY_DRIVER* . If this driver needs exclusive access to a protocol interface, and it requires any drivers that may be using the protocol interface to disconnect, then the driver should use an *Attribute* of *EFI_OPEN_PROTOCOL_BY_DRIVER | EFI_OPEN_PROTOCOL_EXCLUSIVE* .
3. If any of the calls to *OpenProtocol()* in (2) failed with an error other than *EFI_ALREADY_STARTED* , then close all of the protocols opened in (2) that did not return *EFI_ALREADY_STARTED* with *CloseProtocol()* , and return the status code from the *OpenProtocol()* call that returned an error.
4. Use the protocol instances opened in (2) to test to see if this driver supports the controller. Sometimes, just the presence of the protocols is enough of a test. Other times, the services of the protocols opened in (2) are used to further check the identity of the controller. If any of these tests fails, then close all the protocols opened in (2) that did not return *EFI_ALREADY_STARTED* with *CloseProtocol()* and return *EFI_UNSUPPORTED* .
5. Close all protocols opened in (2) that did not return *EFI_ALREADY_STARTED* with *CloseProtocol()* .
6. Return *EFI_SUCCESS* .

Listed below is sample code of the *EFI_DRIVER_BINDING_PROTOCOL.Supported()* function of device driver for a device on the XYZ bus. The XYZ bus is abstracted with the *EFI_XYZ_IO_PROTOCOL* . Just the presence of the *EFI_XYZ_IO_PROTOCOL* on ControllerHandle is enough to determine if this driver supports ControllerHandle. The *gBS* variable is initialized in this driver's entry point.:ref:*efi-system-table* .

```
extern EFI_GUID                          gEfiXyzIoProtocol;
EFI_BOOT_SERVICES                        *gBS;

EFI_STATUS
AbcSupported (
 IN EFI_DRIVER_BINDING_PROTOCOL          *This,
 IN EFI_HANDLE                           ControllerHandle,
 IN EFI_DEVICE_PATH_PROTOCOL             *RemainingDevicePath OPTIONAL
 )

{
 EFI_STATUS                              Status;
 EFI_XYZ_IO_PROTOCOL                     *XyzIo;

Status = gBS->OpenProtocol (
         ControllerHandle,
         &gEfiXyzIoProtocol,
         &XyzIo,
         This->DriverBindingHandle,
         ControllerHandle,
         EFI_OPEN_PROTOCOL_BY_DRIVER
         );
if (EFI_ERROR (Status)) {
 return Status;
}

gBS->CloseProtocol (
     ControllerHandle,
     &gEfiXyzIoProtocol,
     This->DriverBindingHandle,
     ControllerHandle
     );

 return EFI_SUCCESS;
}
```

11.1.3 EFI_DRIVER_BINDING_PROTOCOL.Start()

Summary

Starts a device controller or a bus controller. The *Start()* and efi-driver-binding-protocol-stop-protocols-uefi-driver-model mirror each other.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_DRIVER_BINDING_PROTOCOL_START) (
```

(continues on next page)

(continued from previous page)

```
IN EFI_DRIVER_BINDING_PROTOCOL          *This,
IN EFI_HANDLE                           ControllerHandle,
IN EFI_DEVICE_PATH_PROTOCOL             *RemainingDevicePath OPTIONAL
);
```

Parameters

This

A pointer to the EFI_DRIVER_BINDING_PROTOCOL instance.

ControllerHandle

The handle of the controller to start. This handle must support a protocol interface that supplies an I/O abstraction to the driver.

RemainingDevicePath

A pointer to the remaining portion of a device path. For a bus driver, if this parameter is NULL, then handles for all the children of Controller are created by this driver.

If this parameter is not NULL and the first Device Path Node is not the End of Device Path Node, then only the handle for the child device specified by the first Device Path Node of RemainingDevicePath is created by this driver.

If the first Device Path Node of *RemainingDevicePath* is the End of Device Path Node, no child handle is created by this driver.

Description

This function starts the device specified by Controller with the driver specified by This. Whatever resources are allocated in *Start()* must be freed in *Stop()* . For example, every *EFI_BOOT_SERVICES.AllocatePool()* , *EFI_BOOT_SERVICES.AllocatePages()* , *EFI_BOOT_SERVICES.OpenProtocol()* , and *EFI_BOOT_SERVICES.InstallProtocolInterface()* in *Start()* must be matched with a *EFI_BOOT_SERVICES.FreePool()* , *EFI_BOOT_SERVICES.FreePages()* , *EFI_BOOT_SERVICES.CloseProtocol()* , and *EFI_BOOT_SERVICES.UninstallProtocolInterface()* in *Stop()* .

If Controller is started, then *EFI_SUCCESS* is returned.

If *Controller* could not be started, but can potentially be repaired with configuration or repair operations using the *EFI_DRIVER_HEALTH_PROTOCOL* and this driver produced an instance of the *EFI_DRIVER_HEALTH_PROTOCOL* for *Controller* , then return *EFI_SUCCESS* .

If *Controller* cannot be started due to a device error and the driver does not produce the *EFI_DRIVER_HEALTH_PROTOCOL* for *Controller* , then return *EFI_DEVICE_ERROR* .

If the driver does not support *Controller* then *EFI_DEVICE_ERROR* is returned. This condition will only be met if *Supported()* returns *EFI_SUCCESS* and a more extensive supported check in *Start()* fails.

If there are not enough resources to start the device or bus specified by *Controller* , then *EFI_OUT_OF_RESOURCES* is returned.

If the driver specified by This is a device driver, then RemainingDevicePath is ignored.

If the driver specified by *This* is a bus driver, and *RemainingDevicePath* is *NULL* , then all of the children of *Controller* are discovered and enumerated, and a device handle is created for each child.

If the driver specified by This is a bus driver, and *RemainingDevicePath* is not *NULL* and begins with the End of Device Path node, then the driver must not enumerate any of the children of *Controller* nor create any child device handle. Only the controller initialization should be performed. If the driver implements *EFI_DRIVER_DIAGNOSTICS2_PROTOCOL* , *EFI_COMPONENT_NAME2_PROTOCOL* , *EFI_SERVICE_BINDING_PROTOCOL* , *EFI_DRIVER_FAMILY_OVERRIDE_PROTOCOL* , or

EFI_DRIVER_HEALTH_PROTOCOL , the driver still should install the implemented protocols. If the driver supports *EFI_PLATFORM_TO_DRIVER_CONFIGURATION_PROTOCOL,* the driver still should retrieve and process the configuration information.

If the driver specified by This is a bus driver that is capable of creating one child handle at a time and RemainingDevicePath is not *NULL* and does not begin with the End of Device Path node, then an attempt is made to create the device handle for the child device specified by RemainingDevicePath. Depending on the bus type, all of the child devices may need to be discovered and enumerated, but at most only the device handle for the one child specified by RemainingDevicePath shall be created.

The *Start()* function is designed to be invoked from the EFI boot service *EFI_BOOT_SERVICES.ConnectController()* . As a result, much of the error checking on the parameters to *Start()* has been moved into this common boot service. It is legal to call *Start()* from other locations, but the following calling restrictions must be followed or the system behavior will not be deterministic:

- *ControllerHandle* must be a valid *EFI_HANDLE* .
- If *RemainingDevicePath* is not **NULL** , then it must be a pointer to a naturally aligned *EFI_DEVICE_PATH_PROTOCOL* .
- Prior to calling *Start()* , *EFI_DRIVER_BINDING_PROTOCOL.Supported()* function for the driver specified by *This* must have been called with the same calling parameters, and *Supported()* must have returned *EFI_SUCCESS* .

Status Codes Returned

EFI_SUCCESS	The device was started.
EFI_SUCCESS	The device could not be started because the device needs to be configured by the user or requires a repair operation, and the driver produced the Driver Health Protocol that will return the required configuration and repair operations for this device.
EFI_DEVICE_ERROR	The driver does not produce the Driver Health Protocol and the device could not be started due to a device error.
EFI_DEVICE_ERROR	The driver produces the Driver Health Protocol, and the driver does not support the device.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.

Examples

```
extern EFI_GUID                  gEfiDriverBindingProtocolGuid;
EFI_HANDLE                       DriverImageHandle;
EFI_HANDLE                       ControllerHandle;
EFI_DRIVER_BINDING_PROTOCOL      *DriverBinding;
EFI_DEVICE_PATH_PROTOCOL         *RemainingDevicePath;

//
// Use the DriverImageHandle to get the Driver Binding Protocol instance
//
Status = gBS->OpenProtocol (
         DriverImageHandle,
         &gEfiDriverBindingProtocolGuid,
         &DriverBinding,
         DriverImageHandle,
         NULL,
         EFI_OPEN_PROTOCOL_GET_PROTOCOL
         );
```

(continues on next page)

(continued from previous page)

```
if (EFI_ERROR (Status)) {
  return Status;
}

//
// EXAMPLE #1
//
// Use the Driver Binding Protocol instance to test to see if the
// driver specified by DriverImageHandle supports the controller
// specified by ControllerHandle
//
Status = DriverBinding->Supported (
            DriverBinding,
            ControllerHandle,
            NULL
            );
if (!EFI_ERROR (Status)) {
  Status =  DriverBinding->Start (
            DriverBinding,
            ControllerHandle,
            NULL
           );
}
return Status;

//
// EXAMPLE #2
//
// The RemainingDevicePath parameter can be used to initialize only
// the minimum devices required to boot. For example, maybe we only
// want to initialize 1 hard disk on a SCSI channel. If DriverImageHandle
// is a SCSI Bus Driver, and ControllerHandle is a SCSI Controller, and
// we only want to create a child handle for PUN=3 and LUN=0, then the
// RemainingDevicePath would be SCSI(3,0)/END. The following example
// would return EFI_SUCCESS if the SCSI driver supports creating the
// child handle for PUN=3, LUN=0. Otherwise it would return an error.
//
Status = DriverBinding->Supported (
            DriverBinding,
            ControllerHandle,
            RemainingDevicePath
            );
if (!EFI_ERROR (Status)) {
  Status = DriverBinding->Start (
            DriverBinding,
            ControllerHandle,
            RemainingDevicePath
            );
}

return Status;
```

Pseudo Code

Listed below are the algorithms for the *EFI_DRIVER_BINDING_PROTOCOL.Supported()* function for three different types of drivers. How the *EFI_DRIVER_BINDING_PROTOCOL.Start()* function of a driver is implemented can affect how the *EFI_DRIVER_BINDING_PROTOCOL.Supported()* function is implemented. All of the services in the *EFI Driver Binding Protocol* need to work together to make sure that all resources opened or allocated in *Supported()* and *Start()* are released in *EFI_DRIVER_BINDING_PROTOCOL.Stop()* .

The first algorithm is a simple device driver that does not create any additional handles. It only attaches one or more protocols to an existing handle. The second is a simple bus driver that always creates all of its child handles on the first call to *Start()* . It does not attach any additional protocols to the handle for the bus controller. The third is a more advanced bus driver that can either create one child handles at a time on successive calls to *Start()* , or it can create all of its child handles or all of the remaining child handles in a single call to *Start()*. Once again, it does not attach any additional protocols to the handle for the bus controller.

Device Driver:

1. Ignore the parameter *RemainingDevicePath* ..
2. Open all required protocols with *EFI_BOOT_SERVICES.OpenProtocol()* . A standard driver should use an *Attribute* of *EFI_OPEN_PROTOCOL_BY_DRIVER* . If this driver needs exclusive access to a protocol interface, and it requires any drivers that may be using the protocol interface to disconnect, then the driver should use an *Attribute* of *EFI_OPEN_PROTOCOL_BY_DRIVER* | *EFI_OPEN_PROTOCOL_EXCLUSIVE* . It must use the same *Attribute* value that was used in *Supported()* .
3. If any of the calls to *OpenProtocol()* in (2) returned an error, then close all of the protocols opened in (2) with *EFI_BOOT_SERVICES.CloseProtocol()* , and return the status code from the call to *OpenProtocol()* that returned an error.
4. Initialize the device specified by *ControllerHandle* . If the driver does not support the device specified by *ControllerHandle* , then close all of the protocols opened in (2) with *CloseProtocol()* , and return *EFI_DEVICE_ERROR* . If the driver does support the device specified by ControllerHandle and an error is detected, and that error can not be resolved with the *EFI_DRIVER_HEALTH_PROTOCOL* , then close all of the protocols opened in (2) with *CloseProtocol()* , and return *EFI_DEVICE_ERROR* . If the driver does support the device specified by ControllerHandle and an error is detected, and that error can be resolved with the *EFI_DRIVER_HEALTH_PROTOCOL* , then produce the *EFI_DRIVER_HEALTH_PROTOCOL* for *ControllerHandle* and make sure *EFI_SUCCESS* is returned from *Start()* . In this case, depending on the type of error detected, not all of the following steps may be completed
5. Allocate and initialize all of the data structures that thisdriver requires to manage the device specified by*ControllerHandle* . This would include space for publicprotocols and space for any additional private datastructures that are related to *ControllerHandle* . If anerror occurs allocating the resources, then close all of theprotocols opened in (2) with *CloseProtocol()* , and return *EFI_OUT_OF_RESOURCES* .
6. Install all the new protocol interfaces onto *ControllerHandle* using *EFI_BOOT_SERVICES.InstallMultipleProtocolInterfaces()* . If an error occurs, close all of the protocols opened in (1)with *CloseProtocol()* , and return the error from *InstallMultipleProtocolInterfaces()* .
7. Return *EFI_SUCCESS* .

Bus Driver that creates all of its child handles on the first call to Start():

1. Ignore the parameter *RemainingDevicePath* . with theexception that if the first Device Path Node is the End ofDevice Path Node, skip steps 5-8.
2. Open all required protocols with *EFI_BOOT_SERVICES.OpenProtocol()* .A standard driver should use an *Attribute* of *EFI_OPEN_PROTOCOL_BY_DRIVER* . If this driver needsexclusive access to a protocol interface, and it requiresany drivers that may be using the protocol interface todisconnect, then the driver should use an *Attribute* of*EFI_OPEN_PROTOCOL_BY_DRIVER | EFI_OPEN_PROTOCOL_EXCLUSIVE*. It must use the same *Attribute* value that was used in Supported() *EFI_DRIVER_BINDING_PROTOCOL.Supported()*.

3. If any of the calls to *OpenProtocol()* in (2) returned anerror, then close all of the protocols opened in (2) with *EFI_BOOT_SERVICES.CloseProtocol()* , and return the status code from the call to *OpenProtocol()* that returned an error.
4. Initialize the device specified by *ControllerHandle* . Ifthe driver does not support the device specified by*ControllerHandle* , then close all of the protocols openedin (2) with *CloseProtocol()* , and return*EFI_DEVICE_ERROR* . If the driver does support the devicespecified by *ControllerHandle* and an error is detected,and that error can not be resolved with the*EFI_DRIVER_HEALTH_PROTOCOL* , then close all of theprotocols opened in (2) with *CloseProtocol()* , and return*EFI_DEVICE_ERROR* . If the driver does support the devicespecified by *ControllerHandle* and an error is detected,and that error can be resolved with the*EFI_DRIVER_HEALTH_PROTOCOL* , then produce the*EFI_DRIVER_HEALTH_PROTOCOL* for *ControllerHandle* and makesure *EFI_SUCCESS* is returned from *Start()* . In thiscase, depending on the type of error detected, not all ofthe following steps may be completed.
5. Discover all the child devices of the bus controllerspecified by *ControllerHandle*.
6. If the bus requires it, allocate resources to all the child devices of the bus controller specified by *ControllerHandle*.
7. FOR each child C of *ControllerHandle* :
    - Allocate and initialize all of the data structures that thisdriver requires to manage the child device C. This wouldinclude space for public protocols and space for anyadditional private data structures that are related to thechild device C. If an error occurs allocating the resources,then close all of the protocols opened in (2) with*CloseProtocol()* , and return *EFI_OUT_OF_RESOURCES* .
    - If the bus driver creates device paths for the childdevices, then create a device path for the child C basedupon the device path attached to *ControllerHandle* .
    - Initialize the child device C. If an error occurs, close all of the protocols opened in (2) with *CloseProtocol()* , and return *EFI_DEVICE_ERROR* .
    - Create a new handle for C, and install the protocol interfaces for child device C using *EFI_BOOT_SERVICES.InstallMultipleProtocolInterfaces()* . This may include the *EFI Device Path Protocol* .
    - Call *OpenProtocol()* on behalf of the child C with an *Attribute* of *EFI_OPEN_PROTOCOL_BY_CHILD_CONTROLLER* .
8. END FOR
9. If the bus driver also produces protocols on *ControllerHandle* , then install all the new protocol interfaces onto *ControllerHandle* using *InstallMultipleProtocolInterfaces()* . If an error occurs, close all of the protocols opened in (2) with *CloseProtocol()* , and return the error from *InstallMultipleProtocolInterfaces()* .
10. Return *EFI_SUCCESS* .

Bus Driver that is able to create all or one of its child handles on each call to Start():

1. Open all required protocols with *EFI_BOOT_SERVICES.OpenProtocol()* . A standard driver should use an *Attribute* of *EFI_OPEN_PROTOCOL_BY_DRIVER* . If this driver needs exclusive access to a protocol interface, and it requires any drivers that may be using the protocol interface to disconnect, then the driver should use an *Attribute* of *EFI_OPEN_PROTOCOL_BY_DRIVER* | *EFI_OPEN_PROTOCOL_EXCLUSIVE* . It must use the same *Attribute* value that was used in Supported() *EFI_DRIVER_BINDING_PROTOCOL.Supported()* .
2. If any of the calls to *OpenProtocol()* in (1) returned an error, then close all of the protocols opened in (1) with *EFI_BOOT_SERVICES.CloseProtocol()* , and return the status code from the call to *OpenProtocol()* that returned an error.
3. Initialize the device specified by *ControllerHandle* . If the driver does not support the device specified by *ControllerHandle* , then close all of the protocols opened in (1) with *CloseProtocol()* , and return *EFI_DEVICE_ERROR* . If the driver does support the device specified by *ControllerHandle* and an error is detected, and that error can not be resolved with the *EFI_DRIVER_HEALTH_PROTOCOL* , then close all of

the protocols opened in (1) with *CloseProtocol()* , and return *EFI_DEVICE_ERROR* . If the driver does support the device specified by *ControllerHandle* and an error is detected, and that error can be resolved with the *EFI_DRIVER_HEALTH_PROTOCOL* , then produce the *EFI_DRIVER_HEALTH_PROTOCOL* for *ControllerHandle* and make sure *EFI_SUCCESS* is returned from *Start()* . In this case, depending on the type of error detected, not all of the following steps may be completed.

4. IF *RemainingDevicePath* is not **NULL** , THEN

   a – C is the child device specified by *RemainingDevicePath* . If the first Device Path Node is the End of Device Path Node, proceed to step 6.

   b – Allocate and initialize all of the data structures that this driver requires to manage the child device C. This would include space for public protocols and space for any additional private data structures that are related to the child device C. If an error occurs allocating the resources, then close all of the protocols opened in (1) with *CloseProtocol()* , and return *EFI_OUT_OF_RESOURCES* .

   c – If the bus driver creates device paths for the child devices, then create a device path for the child C based upon the device path attached to *ControllerHandle* .

   d – Initialize the child device C.

   e – Create a new handle for C, and install the protocol interfaces for child device C using *EFI_BOOT_SERVICES.InstallMultipleProtocolInterfaces()* . This may include the *EFI Device Path Protocol* .

   f – Call *OpenProtocol()* on behalf of the child C with an *Attribute* of *EFI_OPEN_PROTOCOL_BY_CHILD_CONTROLLER* .

   ELSE

   a – Discover all the child devices of the bus controller specified by *ControllerHandle* .

   b – If the bus requires it, allocate resources to all the child devices of the bus controller specified by *ControllerHandle* .

   c – FOR each child C of *ControllerHandle*

   Allocate and initialize all of the data structures that this driver requires to manage the child device C. This would include space for public protocols and space for any additional private data structures that are related to the child device C. If an error occurs allocating the resources, then close all of the protocols opened in (1) with *CloseProtocol()* , and return *EFI_OUT_OF_RESOURCES* .

   If the bus driver creates device paths for the child devices, then create a device path for the child C based upon the device path attached to *ControllerHandle* .

   Initialize the child device C.

   Create a new handle for C, and install the protocol interfaces for child device C using *InstallMultipleProtocolInterfaces()* . This may include the *EFI_DEVICE_PATH_PROTOCOL.*

   Call *EFI_BOOT_SERVICES.OpenProtocol()* on behalf of the child C with an *Attribute* of * EFI_OPEN_PROTOCOL_BY_CHILD_CONTROLLER* .

   d – END FOR

5. END IF

6. If the bus driver also produces protocols on *ControllerHandle* , then install all the new protocol interfaces onto *ControllerHandle* using *InstallMultipleProtocolInterfaces()* . If an error occurs, close all of the protocols opened in (2) with *CloseProtocol()* , and return the error from *InstallMultipleProtocolInterfaces()* .

7. Return *EFI_SUCCESS* .

Listed below is sample code of the *EFI_DRIVER_BINDING_PROTOCOL.Start()* function of a device driver for a device on the XYZ bus. The XYZ bus is abstracted with the *EFI_XYZ_IO_PROTOCOL* . This driver does allow the *EFI_XYZ_IO_PROTOCOL* to be shared with other drivers, and just the presence of the *EFI_XYZ_IO_PROTOCOL* on ControllerHandle is enough to determine if this driver supports ControllerHandle. This driver installs the *EFI_ABC_IO_PROTOCOL* on ControllerHandle. The *gBS* variable is initialized in this driver's entry point as shown in the UEFI Driver Model examples in *UEFI Driver Model*.

```
extern EFI_GUID                  gEfiXyzIoProtocol;

}
```

11.1.4 EFI_DRIVER_BINDING_PROTOCOL.Stop()

Summary

Stops a device controller or a bus controller. The *EFI_DRIVER_BINDING_PROTOCOL.Start()* and *Stop()* services of the *EFI_DRIVER_BINDING_PROTOCOL.Stop()* mirror each other.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_DRIVER_BINDING_PROTOCOL_STOP) (
 IN EFI_DRIVER_BINDING_PROTOCOL          *This,
 IN EFI_HANDLE                           ControllerHandle,
 IN UINTN                                NumberOfChildren,
 IN EFI_HANDLE                           *ChildHandleBuffer OPTIONAL
 );
```

Parameters

This

A pointer to the EFI_DRIVER_BINDING_PROTOCOL instance. Type EFI_DRIVER_BINDING_PROTOCOL is defined in *EFI Driver Binding Protocol* .

ControllerHandle

A handle to the device being stopped. The handle must support a bus specific I/O protocol for the driver to use to stop the device.

NumberOfChildren

The number of child device handles in ChildHandleBuffer.

ChildHandleBuffer

An array of child handles to be freed. May be NULL if NumberOfChildren is 0.

Description

This function performs different operations depending on the parameter NumberOfChildren. If NumberOfChildren is not zero, then the driver specified by This is a bus driver, and it is being requested to free one or more of its child handles specified by NumberOfChildren and ChildHandleBuffer. If all of the child handles are freed, then *EFI_SUCCESS* is returned. If NumberOfChildren is zero, then the driver specified by This is either a device driver or a bus driver, and it is being requested to stop the controller specified by ControllerHandle. If ControllerHandle is stopped, then *EFI_SUCCESS* is returned. In either case, this function is required to undo what was performed in *Start()* . Whatever resources are allocated in *Start()* must be freed in *Stop()* . For example, every *EFI_BOOT_SERVICES.AllocatePool()* , *EFI_BOOT_SERVICES.AllocatePages()* , *EFI_BOOT_SERVICES.OpenProtocol()* , and *EFI_BOOT_SERVICES.InstallProtocolInterface()* in *Start()* must be matched with a *EFI_BOOT_SERVICES.FreePool()* , *EFI_BOOT_SERVICES.FreePages()* , *EFI_BOOT_SERVICES.CloseProtocol()* , and *EFI_BOOT_SERVICES.UninstallProtocolInterface()* in *Stop()* .

If ControllerHandle cannot be stopped, then *EFI_DEVICE_ERROR* is returned. If, for some reason, there are not enough resources to stop ControllerHandle, then *EFI_OUT_OF_RESOURCES* is returned.

The *Stop()* function is designed to be invoked from the EFI boot service *EFI_BOOT_SERVICES.DisconnectController()* . As a result, much of the error checking on the parameters to *Stop()* has been moved into this common boot service. It is legal to call *Stop()* from other locations, but the following calling restrictions must be followed or the system behavior will not be deterministic.

- *ControllerHandle* must be a valid *EFI_HANDLE* that was used on a previous call to this same driver's *EFI_DRIVER_BINDING_PROTOCOL.Start()* function.

- The first *NumberOfChildren* handles of *ChildHandleBuffer* must all be a valid *EFI_HANDLE* . In addition, all of these handles must have been created in this driver's *Start()* function, and the *Start()* function must have called *EFI_BOOT_SERVICES.OpenProtocol()* on *ControllerHandle* with an *Attribute* of *EFI_OPEN_PROTOCOL_BY_CHILD_CONTROLLER* .

Status Codes Returned

EFI_SUCCESS	The device was stopped.
EFI_DEVICE_ERROR	The device could not be stopped due to a device error.

Examples

```
extern EFI_GUID                gEfiDriverBindingProtocolGuid;
EFI_HANDLE                     DriverImageHandle;
EFI_HANDLE                     ControllerHandle;
EFI_HANDLE                     ChildHandle;
EFI_DRIVER_BINDING_PROTOCOL    *DriverBinding;

//
// Use the DriverImageHandle to get the Driver Binding Protocol instance
//
Status = gBS->OpenProtocol (
         DriverImageHandle,
         &gEfiDriverBindingProtocolGuid,
         &DriverBinding,
         DriverImageHandle,
         NULL,
         EFI_OPEN_PROTOCOL_GET_PROTOCOL
         );
if (EFI_ERROR (Status)) {
  return Status;
}

//
// Use the Driver Binding Protocol instance to free the child
// specified by ChildHandle. Then, use the Driver Binding
// Protocol to stop ControllerHandle.
//
Status = DriverBinding->Stop (
         DriverBinding,
         ControllerHandle,
         1,
         &ChildHandle
         );

Status = DriverBinding->Stop (
         DriverBinding,
         ControllerHandle,
         0,
         NULL
         );
```

Pseudo Code

Device Driver:

1. Uninstall all the protocols that were installed onto *ControllerHandle* in *EFI_DRIVER_BINDING_PROTOCOL.Start()* .
2. Close all the protocols that were opened on behalf of *ControllerHandle* in *Start()* .
3. Free all the structures that were allocated on behalf of *ControllerHandle* in *Start()* .
4. Return *EFI_SUCCESS* .

Bus Driver that creates all of its child handles on the first call to Start():

Bus Driver that is able to create all or one of its child handles on each call to Start():

1. IF *NumberOfChildren* is zero THEN:
    - Uninstall all the protocols that were installed onto *ControllerHandle* in *Start()* .
    - Close all the protocols that were opened on behalf of *ControllerHandle* in *Start()* .
    - Free all the structures that were allocated on behalf of *ControllerHandle* in *Start()* .
2. ELSE
    - FOR each child C in *ChildHandleBuffer*: Uninstall all the protocols that were installed onto C in *Start()* . Close all the protocols that were opened on behalf of C in *Start()* . Free all the structures that were allocated on behalf of C in *Start()* .
    - END FOR
3. END IF
4. Return *EFI_SUCCESS.*

Listed below is sample code of the *EFI_DRIVER_BINDING_PROTOCOL.Stop()* function of a device driver for a device on the XYZ bus. The XYZ bus is abstracted with the *EFI_XYZ_IO_PROTOCOL* . This driver does allow the *EFI_XYZ_IO_PROTOCOL* to be shared with other drivers, and just the presence of the *EFI_XYZ_IO_PROTOCOL* on ControllerHandle is enough to determine if this driver supports ControllerHandle. This driver installs the *EFI_ABC_IO_PROTOCOL* on ControllerHandle in *EFI_DRIVER_BINDING_PROTOCOL.Start()* . The *gBS* variable is initialized in this driver's entry point.:ref:*efi-system-table_efi_system_table* . extern EFI_GUID

```

  }

  return Status;

}
```

11.2 EFI Platform Driver Override Protocol

This section provides a detailed description of the *EFI_PLATFORM_DRIVER_OVERRIDE_PROTOCOL* . This protocol can override the default algorithm for matching drivers to controllers.

EFI_PLATFORM_DRIVER_OVERRIDE_PROTOCOL

Summary

This protocol matches one or more drivers to a controller. A platform driver produces this protocol, and it is installed on a separate handle. This protocol is used by the *EFI_BOOT_SERVICES.ConnectController()* boot service to select the best driver for a controller. All of the drivers returned by this protocol have a higher precedence than drivers found from an EFI Bus Specific Driver Override Protocol or drivers found from the general UEFI driver Binding search algorithm. If more than one driver is returned by this protocol, then the drivers are returned in order from highest precedence to lowest precedence.

GUID

```
#define EFI_PLATFORM_DRIVER_OVERRIDE_PROTOCOL_GUID \
{0x6b30c738,0xa391,0x11d4,\
   {0x9a,0x3b,0x00,0x90,0x27,0x3f,0xc1,0x4d}}
```

Protocol Interface Structure

```
typedef struct _EFI_PLATFORM_DRIVER_OVERRIDE_PROTOCOL {
 EFI_PLATFORM_DRIVER_OVERRIDE_GET_DRIVER           GetDriver;
 EFI_PLATFORM_DRIVER_OVERRIDE_GET_DRIVER_PATH      GetDriverPath;
 EFI_PLATFORM_DRIVER_OVERRIDE_DRIVER_LOADED        DriverLoaded;
} EFI_PLATFORM_DRIVER_OVERRIDE_PROTOCOL;
```

Parameters

GetDriver
Retrieves the image handle of a platform override driver for a controller in the system. See the *EFI_PLATFORM_DRIVER_OVERRIDE_PROTOCOL.GetDriver()* function description.

GetDriverPath
Retrieves the device path of a platform override driver for a controller in the system. See the GetDriverPath() *EFI_PLATFORM_DRIVER_OVERRIDE_PROTOCOL.GetDriverPath()* function description.

DriverLoaded
This function is used after a driver has been loaded using a device path returned by *EFI_PLATFORM_DRIVER_OVERRIDE_PROTOCOL.GetDriverPath()* This function associates a device path to an image handle, so the image handle can be returned the next time that GetDriver() is called for the same controller. See the DriverLoaded() *EFI_PLATFORM_DRIVER_OVERRIDE_PROTOCOL.DriverLoaded()* function description.

Description

The *EFI_PLATFORM_DRIVER_OVERRIDE_PROTOCOL* is used by the EFI boot service *EFI_BOOT_SERVICES.ConnectController()* to determine if there is a platform specific driver override for a controller that is about to be started. The bus drivers in a platform will use a bus defined matching algorithm for matching drivers to controllers. This protocol allows the platform to override the bus driver's default driver matching algorithm. This protocol can be used to specify the drivers for on-board devices whose drivers may be in a system ROM not directly associated with the on-board controller, or it can even be used to manage the matching of drivers and controllers in add-in cards. This can be very useful if there are two adapters that are identical except for the revision of the driver in the adapter's ROM. This protocol, along with a platform configuration utility, could specify which of the two drivers to use for each of the adapters.

The drivers that this protocol returns can be either in the form of an image handle or a device path. *EFI_BOOT_SERVICES.ConnectController()* can only use image handles, so *ConnectController()* is required to use the *EFI_PLATFORM_DRIVER_OVERRIDE_PROTOCOL.GetDriver()* . A different component, such as the Boot Manager, will have to use the GetDriverPath() *EFI_PLATFORM_DRIVER_OVERRIDE_PROTOCOL.GetDriverPath()* service to retrieve the list of drivers that need to be loaded from I/O devices. Once a driver has been loaded and started, this same component can use the DriverLoaded() *EFI_PLATFORM_DRIVER_OVERRIDE_PROTOCOL.DriverLoaded()* service to associate the device path of a driver with the image handle of the loaded driver. Once this association has been established, the image handle can then be returned by the *GetDriver()* service the next time it is called by *ConnectController()* .

11.2.1 EFI_PLATFORM_DRIVER_OVERRIDE_PROTOCOL.GetDriver()

Summary

Retrieves the image handle of the platform override driver for a controller in the system.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PLATFORM_DRIVER_OVERRIDE_GET_DRIVER) (
  IN    EFI_PLATFORM_DRIVER_OVERRIDE_PROTOCOL       *This,
  IN    EFI_HANDLE                                  ControllerHandle,
  IN OUT EFI_HANDLE                                *DriverImageHandle
  );
```

Parameters

This
A pointer to the *EFI Platform Driver Override Protocol* instance.

ControllerHandle
The device handle of the controller to check if a driver override exists.

DriverImageHandle
On input, a pointer to the previous driver image handle returned by GetDriver(). On output, a pointer to the next driver image handle. Passing in a NULL, will return the first driver image handle for *ControllerHandle.*

Description

This function is used to retrieve a driver image handle that is selected in a platform specific manner. The first driver image handle is retrieved by passing in a DriverImageHandle value of *NULL* . This will cause the first driver image handle to be returned in DriverImageHandle. On each successive call, the previous value of DriverImageHandle must be passed in. If a call to this function returns a valid driver image handle, then *EFI_SUCCESS* is returned. This process is repeated until *EFI_NOT_FOUND* is returned. If a DriverImageHandle is passed in that was not returned on a prior call to this function, then *EFI_INVALID_PARAMETER* is returned. If ControllerHandle is *NULL* , then *EFI_INVALID_PARAMETER* is returned. The first driver image handle has the highest precedence, and the last driver image handle has the lowest precedence. This ordered list of driver image handles is used by the boot service *EFI_BOOT_SERVICES.ConnectController()* to search for the best driver for a controller.

Status Codes Returned

EFI_SUCCESS	The driver override for ControllerHandle was returned in DriverImageHandle.
EFI_NOT_FOUND	A driver override for ControllerHandle was not found.
EFI_INVALID_PARAMETER	The handle specified by ControllerHandle is not a valid handle.

continues on next page

Table 11.4 – continued from previous page

EFI_INVALID_PARAMETER	DriverImageHandle is not a handle that was returned on a previous call to GetDriver().

11.2.2 EFI_PLATFORM_DRIVER_OVERRIDE_PROTOCOL.GetDriverPath()

Summary

Retrieves the device path of the platform override driver for a controller in the system.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PLATFORM_DRIVER_OVERRIDE_GET_DRIVER_PATH) (
 IN EFI_PLATFORM_DRIVER_OVERRIDE_PROTOCOL             *This,
 IN EFI_HANDLE                                        ControllerHandle,
 IN OUT EFI_DEVICE_PATH_PROTOCOL                      **DriverImagePath
 );
```

Parameters

This

A pointer to the *EFI Platform Driver Override Protocol* instance.

ControllerHandle

The device handle of the controller to check if a driver override exists.

DriverImagePath

On input, a pointer to the previous driver device path returned by GetDriverPath(). On output, a pointer to the next driver device path. Passing in a pointer to NULL, will return the first driver device path for *ControllerHandle*.

Description

This function is used to retrieve a driver device path that is selected in a platform specific manner. The first driver device path is retrieved by passing in a DriverImagePath value that is a pointer to *NULL* . This will cause the first driver device path to be returned in DriverImagePath. On each successive call, the previous value of DriverImagePath must be passed in. If a call to this function returns a valid driver device path, then *EFI_SUCCESS* is returned. This process is repeated until *EFI_NOT_FOUND* is returned. If a DriverImagePath is passed in that was not returned on a prior call to this function, then *EFI_INVALID_PARAMETER* is returned. If ControllerHandle is *NULL* , then *EFI_INVALID_PARAMETER* is returned. The first driver device path has the highest precedence, and the last driver device path has the lowest precedence. This ordered list of driver device paths is used by a platform specific component, such as the EFI Boot Manager, to load and start the platform override drivers by using the EFI boot services *EFI_BOOT_SERVICES.LoadImage()* and *EFI_BOOT_SERVICES.StartImage()* . Each time one of these drivers is loaded and started, the DriverLoaded() *EFI_PLATFORM_DRIVER_OVERRIDE_PROTOCOL.DriverLoaded()* service is called.

Status Codes Returned

EFI_SUCCESS	The driver override for ControllerHandle was returned in DriverImagePath.
EFI_UNSUPPORTED	The operation is not supported.
EFI_NOT_FOUND	A driver override for ControllerHandle was not found.
EFI_INVALID_PARAMETER	The handle specified by ControllerHandle is not a valid handle.
EFI_INVALID_PARAMETER	DriverImagePath is not a device path that was returned on a previous call to GetDriverPath().

11.2.3 EFI_PLATFORM_DRIVER_OVERRIDE_PROTOCOL.DriverLoaded()

Summary

Used to associate a driver image handle with a device path that was returned on a prior call to the GetDriverPath() *EFI_PLATFORM_DRIVER_OVERRIDE_PROTOCOL.GetDriverPath()* service. This driver image handle will then be available through the *EFI_PLATFORM_DRIVER_OVERRIDE_PROTOCOL.GetDriver()* service.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PLATFORM_DRIVER_OVERRIDE_DRIVER_LOADED) (
  IN EFI_PLATFORM_DRIVER_OVERRIDE_PROTOCOL         *This,
  IN EFI_HANDLE                                    ControllerHandle,
  IN EFI_DEVICE_PATH_PROTOCOL                      *DriverImagePath,
  IN EFI_HANDLE                                    DriverImageHandle
  );
```

Parameters

This
A pointer to the *EFI Platform Driver Override Protocol* instance.

ControllerHandle
The device handle of a controller. This must match the controller handle that was used in a prior call to GetDriver() to retrieve DriverImagePath.

DriverImagePath
A pointer to the driver device path that was returned in a prior call to GetDriverPath().

DriverImageHandle
The driver image handle that was returned by *EFI_BOOT_SERVICES.LoadImage()* when the driver specified by DriverImagePath was loaded into memory.

Description

This function associates the image handle specified by DriverImageHandle with the device path of a driver specified by DriverImagePath. DriverImagePath must be a value that was returned on a prior call to *GetDriverPath()* for the controller specified by ControllerHandle. Once this association has been established, then the service *GetDriver()* must return DriverImageHandle as one of the override drivers for the controller specified by ControllerHandle.

If the association between the image handle specified by DriverImageHandle and the device path specified by DriverImagePath is established for the controller specified by ControllerHandle, then *EFI_SUCCESS* is returned. If ControllerHandle is *NULL* , or DriverImagePath is not a valid device path, or DriverImageHandle is *NULL* , then *EFI_INVALID_PARAMETER* is returned. If DriverImagePath is not a device path that was returned on a prior call to *EFI_PLATFORM_DRIVER_OVERRIDE_PROTOCOL.GetDriver()* for the controller specified by ControllerHandle, then *EFI_NOT_FOUND* is returned.

Status Codes Returned

EFI_SUCCESS	The association between DriverImagePath and DriverImageHandle was established for the controller specified by ControllerHandle.
EFI_UNSUPPORTED	The operation is not supported.
EFI_NOT_FOUND	DriverImagePath is not a device path that was returned on a prior call to GetDriverPath() for the controller specified by ControllerHandle.
EFI_INVALID_PARAMETER	ControllerHandle is not a valid device handle.
EFI_INVALID_PARAMETER	DriverImagePath is not a valid device path.

continues on next page

Table 11.6 – continued from previous page

EFI_INVALID_PARAMETER	DriverImageHandle is not a valid image handle.

11.3 EFI Bus Specific Driver Override Protocol

This section provides a detailed description of the *EFI_BUS_SPECIFIC_DRIVER_OVERRIDE_PROTOCOL* . Bus drivers that have a bus specific algorithm for matching drivers to controllers are required to produce this protocol for each controller. For example, a PCI Bus Driver will produce an instance of this protocol for every PCI controller that has a PCI option ROM that contains one or more UEFI drivers. The protocol instance is attached to the handle of the PCI controller.

11.3.1 EFI_BUS_SPECIFIC_DRIVER_OVERRIDE_PROTOCOL

Summary

This protocol matches one or more drivers to a controller. This protocol is produced by a bus driver, and it is installed on the child handles of buses that require a bus specific algorithm for matching drivers to controllers. This protocol is used by the *EFI_BOOT_SERVICES.ConnectController()* boot service to select the best driver for a controller. All of the drivers returned by this protocol have a higher precedence than drivers found in the general EFI Driver Binding search algorithm, but a lower precedence than those drivers returned by the EFI Platform Driver Override Protocol. If more than one driver image handle is returned by this protocol, then the drivers image handles are returned in order from highest precedence to lowest precedence.

GUID

```
#define EFI_BUS_SPECIFIC_DRIVER_OVERRIDE_PROTOCOL_GUID \
 {0x3bc1b285,0x8a15,0x4a82,\
  {0xaa,0xbf,0x4d,0x7d,0x13,0xfb,0x32,0x65}}
```

Protocol Interface Structure

```
typedef struct _EFI_BUS_SPECIFIC_DRIVER_OVERRIDE_PROTOCOL {
 EFI_BUS_SPECIFIC_DRIVER_OVERRIDE_GET_DRIVER GetDriver;
  } EFI_BUS_SPECIFIC_DRIVER_OVERRIDE_PROTOCOL;
```

Parameters

GetDriver

Uses a bus specific algorithm to retrieve a driver image handle for a controller. See the *EFI_BUS_SPECIFIC_DRIVER_OVERRIDE_PROTOCOL.GetDriver()* function description.

Description

The *EFI_BUS_SPECIFIC_DRIVER_OVERRIDE_PROTOCOL* provides a mechanism for bus drivers to override the default driver selection performed by the *ConnectController()* boot service. This protocol is attached to the handle of a child device after the child handle is created by the bus driver. The service in this protocol can return a bus specific override driver to *ConnectController()* . *ConnectController()* must call this service until all of the bus specific override drivers have been retrieved. *ConnectController()* uses this information along with the EFI Platform Driver Override Protocol and all of the EFI Driver Binding protocol instances to select the best drivers for a controller. Since a controller can be managed by more than one driver, this protocol can return more than one bus specific override driver.

11.3.2 EFI_BUS_SPECIFIC_DRIVER_OVERRIDE_PROTOCOL.GetDriver()

Summary

Uses a bus specific algorithm to retrieve a driver image handle for a controller.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_BUS_SPECIFIC_DRIVER_OVERRIDE_GET_DRIVER) (
  IN EFI_BUS_SPECIFIC_DRIVER_OVERRIDE_PROTOCOL        *This,
  IN OUT EFI_HANDLE                                   *DriverImageHandle
  );
```

Parameters

This
A pointer to the *EFI_BUS_SPECIFIC_DRIVER_OVERRIDE_PROTOCOL* instance.

DriverImageHandle
On input, a pointer to the previous driver image handle returned by GetDriver(). On output, a pointer to the next driver image handle. Passing in a NULL, will return the first driver image handle.

Description

This function is used to retrieve a driver image handle that is selected in a bus specific manner. The first driver image handle is retrieved by passing in a DriverImageHandle value of *NULL* . This will cause the first driver image handle to be returned in DriverImageHandle. On each successive call, the previous value of DriverImageHandle must be passed in. If a call to this function returns a valid driver image handle, then *EFI_SUCCESS* is returned. This process is repeated until *EFI_NOT_FOUND* is returned. If a DriverImageHandle is passed in that was not returned on a prior call to this function, then *EFI_INVALID_PARAMETER* is returned. The first driver image handle has the highest precedence, and the last driver image handle has the lowest precedence. This ordered list of driver image handles is used by the boot service *EFI_BOOT_SERVICES.ConnectController()* to search for the best driver for a controller.

Status Codes Returned

EFI_SUCCESS	A bus specific override driver is returned in DriverImageHandle.
EFI_NOT_FOUND	The end of the list of override drivers was reached. A bus specific override driver is not returned in DriverImageHandle.
EFI_INVALID_PARAMETER	DriverImageHandle is not a handle that was returned on a previous call to GetDriver().

11.4 EFI Driver Diagnostics Protocol

This section provides a detailed description of the *EFI_DRIVER_DIAGNOSTICS2_PROTOCOL* . This is a protocol that allows a UEFI driver to perform diagnostics on a controller that the driver is managing.

11.4.1 EFI_DRIVER_DIAGNOSTICS2_PROTOCOL

Summary

Used to perform diagnostics on a controller that a UEFI

GUID

```
#define EFI_DRIVER_DIAGNOSTICS_PROTOCOL_GUID \
 {0x4d330321,0x025f,0x4aac,\
  {0x90,0xd8,0x5e,0xd9,0x00,0x17,0x3b,0x63}}
```

Protocol Interface Structure

```
typedef struct _EFI_DRIVER_DIAGNOSTICS2_PROTOCOL {
  EFI_DRIVER_DIAGNOSTICS2_RUN_DIAGNOSTICS       RunDiagnostics;
  CHAR8                                         *SupportedLanguages;
 } EFI_DRIVER_DIAGNOSTICS2_PROTOCOL;
```

Parameters

RunDiagnostics
Runs diagnostics on a controller. See the RunDiagnostics() *EFI_DRIVER_DIAGNOSTICS2_PROTOCOL.RunDiagnostics()* function description.

SupportedLanguages
A Null-terminated ASCII string that contains one or more supported language codes. This is the list of language codes that this protocol supports. The number of languages supported by a driver is up to the driver writer. SupportedLanguages is specified in RFC 4646 format. *Appendix M — Formats — Language Codes and Language Code Arrays* for the format of language codes and language code arrays.

Description

The *EFI_DRIVER_DIAGNOSTICS2_PROTOCOL* is used by a platform management utility to allow the user to run driver specific diagnostics on a controller. This protocol is optionally attached to the image handle of driver in the driver's entry point. The platform management utility can collect all the *EFI_DRIVER_DIAGNOSTICS2_PROTOCOL* instances present in the system, and present the user with a menu of the controllers that have diagnostic capabilities. This platform management utility is invoked through a platform component such as the EFI Boot Manager.

11.4.2 EFI_DRIVER_DIAGNOSTICS2_PROTOCOL.RunDiagnostics()

Summary

Runs diagnostics on a controller.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_DRIVER_DIAGNOSTICS2_RUN_DIAGNOSTICS) (
 IN EFI_DRIVER_DIAGNOSTICS2_PROTOCOL               *This,
 IN EFI_HANDLE                                     ControllerHandle,
 IN EFI_HANDLE                                     ChildHandle OPTIONAL,
 IN EFI_DRIVER_DIAGNOSTIC_TYPE                     DiagnosticType,
 IN CHAR8                                          *Language,
 OUT EFI_GUID                                      **ErrorType,
 OUT UINTN                                         *BufferSize,
```

(continues on next page)

(continued from previous page)

```
OUT CHAR16                                              **Buffer
);
```

Parameters

This
A pointer to the *EFI_DRIVER_DIAGNOSTICS2_PROTOCOL* instance.

ControllerHandle
The handle of the controller to run diagnostics on.

ChildHandle
The handle of the child controller to run diagnostics on. This is an optional parameter that may be NULL. It will be NULL for device drivers. It will also be NULL for a bus drivers that attempt to run diagnostics on the bus controller. It will not be NULL for a bus driver that attempts to run diagnostics on one of its child controllers.

DiagnosticType
Indicates type of diagnostics to perform on the controller specified by ControllerHandle and ChildHandle. See "Related Definitions" for the list of supported types.

Language
A pointer to a Null-terminated ASCII string array indicating the language. This is the language in which the optional error message should be returned in Buffer, and it must match one of the languages specified in SupportedLanguages. The number of languages supported by a driver is up to the driver writer. Language is specified in RFC 4646 language code format. *Appendix M — Formats — Language Codes and Language Code Arrays*

Callers of interfaces that require RFC 4646 language codes to retrieve a Unicode string must use the RFC 4647 algorithm to lookup the Unicode string with the closest matching RFC 4646 language code.

ErrorType
A GUID that defines the format of the data returned in Buffer.

BufferSize
The size, in bytes, of the data returned in Buffer.

Buffer
A buffer that contains a Null-terminated string plus some additional data whose format is defined by ErrorType. Buffer is allocated by this function with *EFI_BOOT_SERVICES.AllocatePool()* , and it is the caller's responsibility to free it with a call to *EFI_BOOT_SERVICES.FreePool()* .

Description

This function runs diagnostics on the controller specified by ControllerHandle and ChildHandle. DiagnoticType specifies the type of diagnostics to perform on the controller specified by ControllerHandle and ChildHandle. If the driver specified by This does not support the language specified by Language, then *EFI_UNSUPPORTED* is returned. If the controller specified by ControllerHandle and ChildHandle is not supported by the driver specified by This, then *EFI_UNSUPPORTED* is returned. If the diagnostics type specified by DiagnosticType is not supported by this driver, then *EFI_UNSUPPORTED* is returned. If there are not enough resources available to complete the diagnostic, then *EFI_OUT_OF_RESOURCES* is returned. If the controller specified by ControllerHandle and ChildHandle passes the diagnostic, then *EFI_SUCCESS* is returned. Otherwise, *EFI_DEVICE_ERROR* is returned.

If the language specified by Language is supported by this driver, then status information is returned in ErrorType, BufferSize, and Buffer. Buffer contains a Null-terminated string followed by additional data whose format is defined by ErrorType. BufferSize is the size of Buffer is bytes, and it is the caller's responsibility to call *FreePool()* on Buffer when the caller is done with the return data. If there are not enough resources available to return the status information, then *EFI_OUT_OF_RESOURCES* is returned.

Related Definitions

```
//*******************************************************
// EFI_DRIVER_DIAGNOSTIC_TYPE
//*******************************************************
typedef enum {
  EfiDriverDiagnosticTypeStandard         = 0,
  EfiDriverDiagnosticTypeExtended         = 1,
  EfiDriverDiagnosticTypeManufacturing    = 2,
  EfiDriverDiagnosticTypeCancel           = 3,
  EfiDriverDiagnosticTypeMaximum
} EFI_DRIVER_DIAGNOSTIC_TYPE;
```

EfiDriverDiagnosticTypeStandard

> Performs standard diagnostics on the controller. This diagnostic type is required to be supported by all implementations of this protocol.

EfiDriverDiagnosticTypeExtended

> This is an optional diagnostic type that performs diagnostics on the controller that may take an extended amount of time to execute.

EfiDriverDiagnosticTypeManufacturing

> This is an optional diagnostic type that performs diagnostics on the controller that are suitable for a manufacturing and test environment.

EfiDriverDiagnosticTypeCancel

> This is an optional diagnostic type that would only be used in the situation where an EFI_NOT_READY had been returned by a previous call to *RunDiagnostics()* and there is a desire to cancel the current running diagnostics operation.

Status Codes Returned

EFI_SUCCESS	The controller specified by ControllerHandle and ChildHandle passed the diagnostic.
EFI_ACCESS_DENIED	The request for initiating diagnostics was unable to be completed due to some underlying hardware or software state.
EFI_INVALID_PARAMETER	ControllerHandle is *NULL* .
EFI_INVALID_PARAMETER	The driver specified by *This* is not a device driver, and *ChildHandle* is not *NULL* .
EFI_INVALID_PARAMETER	Language is NULL.
EFI_INVALID_PARAMETER	ErrorType is NULL.
EFI_INVALID_PARAMETER	*BufferSize* is *NULL* .
EFI_INVALID_PARAMETER	Buffer is NULL.
EFI_UNSUPPORTED	The driver specified by *This* does not support running diagnostics for the controller specified by ControllerHandle and ChildHandle.
EFI_UNSUPPORTED	The driver specified by This does not support the type of diagnostic specified by DiagnosticType.
EFI_UNSUPPORTED	The driver specified by This does not support the language specified by Language.
EFI_OUT_OF_RESOURCES	There are not enough resources available to complete the diagnostics.
EFI_OUT_OF_RESOURCES	There are not enough resources available to return the status information in ErrorType, BufferSize, and Buffer.
EFI_DEVICE_ERROR	The controller specified by ControllerHandle and ChildHandle did not pass the diagnostic.

continues on next page

Table 11.8 – continued from previous page

EFI_NOT_READY	The diagnostic operation was started, but not yet completed.

11.5 EFI Component Name Protocol

This section provides a detailed description of the *EFI_COMPONENT_NAME2_PROTOCOL* . This is a protocol that allows an driver to provide a user readable name of a UEFI Driver, and a user readable name for each of the controllers that the driver is managing. This protocol is used by platform management utilities that wish to display names of components. These names may include the names of expansion slots, external connectors, embedded devices, and add-in devices.

11.5.1 EFI_COMPONENT_NAME2_PROTOCOL

Summary

Used to retrieve user readable names of drivers and controllers managed by UEFI Drivers.

GUID

```
#define EFI_COMPONENT_NAME2_PROTOCOL_GUID \
 {0x6a7a5cff, 0xe8d9, 0x4f70,\
  {0xba, 0xda, 0x75, 0xab, 0x30,0x25, 0xce, 0x14}}
```

Protocol Interface Structure

```
typedef struct _EFI_COMPONENT_NAME2_PROTOCOL {
 EFI_COMPONENT_NAME_GET_DRIVER_NAME             GetDriverName;
 EFI_COMPONENT_NAME_GET_CONTROLLER_NAME         GetControllerName;
 CHAR8                                          *SupportedLanguages;
} EFI_COMPONENT_NAME2_PROTOCOL;
```

Parameters

GetDriverName

Retrieves a string that is the user readable name of the driver. See the GetDriverName() *EFI_COMPONENT_NAME2_PROTOCOL.GetDriverName()* function description.

GetControllerName

Retrieves a string that is the user readable name of a controller that is being managed by a driver. See the GetControllerName() *EFI_COMPONENT_NAME2_PROTOCOL.GetControllerName()* function description.

SupportedLanguages

A Null-terminated ASCII string array that contains one or more supported language codes. This is the list of language codes that this protocol supports. The number of languages supported by a driver is up to the driver writer. SupportedLanguages is specified in RFC 4646 format. *Appendix M — Formats — Language Codes and Language Code Arrays*

Description

The *EFI_COMPONENT_NAME2_PROTOCOL* is used retrieve a driver's user readable name and the names of all the controllers that a driver is managing from the driver's point of view. Each of these names is returned as a Null-terminated string. The caller is required to specify the language in which the string is returned, and this language must be present in the list of languages that this protocol supports specified by SupportedLanguages.

11.5.2 EFI_COMPONENT_NAME2_PROTOCOL.GetDriverName()

Summary

Retrieves a string that is the user readable name of the driver.

Prototype

```
typedef
EFI_STATUS
EFIAPI *EFI_COMPONENT_NAME_GET_DRIVER_NAME) (
  IN EFI_COMPONENT_NAME2_PROTOCOL           *This,
  IN CHAR8                                  *Language,
  OUT CHAR16                                **DriverName
  );
```

Parameters

This

A pointer to the *EFI_COMPONENT_NAME2_PROTOCOL* instance.

Language

A pointer to a Null-terminated ASCII string array indicating the language. This is the language of the driver name that the caller is requesting, and it must match one of the languages specified in SupportedLanguages. The number of languages supported by a driver is up to the driver writer. Language is specified in RFC 4646 language code format. *Appendix M — Formats — Language Codes and Language Code Arrays* for the format of language codes.

Callers of interfaces that require RFC 4646 language codes to retrieve a Unicode string must use the RFC 4647 algorithm to lookup the Unicode string with the closest matching RFC 4646 language code.

DriverName

A pointer to the string to return. This string is the name of the driver specified by This in the language specified by Language.

Description

This function retrieves the user readable name of a driver in the form of a string. If the driver specified by This has a user readable name in the language specified by Language, then a pointer to the driver name is returned in DriverName, and *EFI_SUCCESS* is returned. If the driver specified by This does not support the language specified by Language, then *EFI_UNSUPPORTED* is returned.

Status Codes Returned

EFI_SUCCESS	The string for the user readable name in the language specified by Language for the driver specified by This was returned in DriverName.
EFI_INVALID_PARAMETER	Language is NULL.
EFI_INVALID_PARAMETER	DriverName is NULL.
EFI_UNSUPPORTED	The driver specified by This does not support the language specified by Language.

11.5.3 EFI_COMPONENT_NAME2_PROTOCOL.GetControllerName()

Summary

Retrieves a string that is the user readable name of the controller that is being managed by a driver.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_COMPONENT_NAME_GET_CONTROLLER_NAME) (
  IN EFI_COMPONENT_NAME2_PROTOCOL              *This,
  IN EFI_HANDLE                                ControllerHandle,
  IN EFI_HANDLE                                ChildHandle OPTIONAL,
  IN CHAR8                                     *Language,
  OUT CHAR16                                   **ControllerName
  );
```

Parameters

This
A pointer to the *EFI_COMPONENT_NAME2_PROTOCOL* instance.

ControllerHandle
The handle of a controller that the driver specified by This is managing. This handle specifies the controller whose name is to be returned.

ChildHandle
The handle of the child controller to retrieve the name of. This is an optional parameter that may be NULL. It will be NULL for device drivers. It will also be NULL for bus drivers that attempt to retrieve the name of the bus controller. It will not be NULL for a bus driver that attempts to retrieve the name of a child controller.

Language
A pointer to a Null- terminated ASCII string array indicating the language. This is the language of the controller name that the caller is requesting, and it must match one of the languages specified in SupportedLanguages. The number of languages supported by a driver is up to the driver writer. Language is specified in RFC 4646 language code format. *Appendix M — Formats — Language Codes and Language Code Arrays* for the format of language codes.

Callers of interfaces that require RFC 4646 language codes to retrieve a Unicode string must use the RFC 4647 algorithm to lookup the Unicode string with the closest matching RFC 4646 language code.

ControllerName
A pointer to the string to return. This string is the name of the controller specified by ControllerHandle and ChildHandle in the language specified by Language from the point of view of the driver specified by This.

Description

This function retrieves the user readable name of the controller specified by ControllerHandle and ChildHandle in the form of a string. If the driver specified by This has a user readable name in the language specified by Language, then a pointer to the controller name is returned in ControllerName, and *EFI_SUCCESS* is returned.

If the driver specified by This is not currently managing the controller specified by ControllerHandle and ChildHandle, then *EFI_UNSUPPORTED* is returned.

If the driver specified by This does not support the language specified by Language, then *EFI_UNSUPPORTED* is returned.

Status Codes Returned

EFI_SUCCESS	The string for the user readable name specified by This, ControllerHandle, ChildHandle, and Language was returned in ControllerName.
EFI_INVALID_PARAMETER	ControllerHandle is *NULL* .
EFI_INVALID_PARAMETER	The driver specified by *This* is not a device driver, and *ChildHandle* is not *NULL* .
EFI_INVALID_PARAMETER	Language is NULL.
EFI_INVALID_PARAMETER	ControllerName is NULL.
EFI_UNSUPPORTED	The driver specified by *This* is a device driver and *ChildHandle* is not *NULL* .
EFI_UNSUPPORTED	The driver specified by *This* is not currently managing the controller specified by *ControllerHandle* and *ChildHandle* .
EFI_UNSUPPORTED	The driver specified by *This* does not support the language specified by *Language* .

11.6 EFI Service Binding Protocol

This section provides a detailed description of the *EFI_SERVICE_BINDING_PROTOCOL* . This protocol may be produced only by drivers that follow the UEFI Driver Model. Use this protocol with the *EFI Driver Binding Protocol* to produce a set of protocols related to a device. The *EFI_DRIVER_BINDING_PROTOCOL* supports simple layering of protocols on a device, but it does not support more complex relationships such as trees or graphs. The *EFI_SERVICE_BINDING_PROTOCOL* provides a member function to create a child handle with a new protocol installed on it, and another member function to destroy a previously created child handle. These member functions apply equally to all drivers.

11.6.1 EFI_SERVICE_BINDING_PROTOCOL

Summary

Provides services that are required to create and destroy child handles that support a given set of protocols.

GUID

This protocol does not have its own GUID. Instead, drivers for other protocols will define a GUID that shares the same protocol interface as the *EFI_SERVICE_BINDING_PROTOCOL* . The protocols defined in this document that have this property include for example the following:

- `EFI_MANAGED_NETWORK_SERVICE_BINDING_PROTOCOL`
- `EFI_ARP_SERVICE_BINDING_PROTOCOL`
- `EFI_EAP_SERVICE_BINDING_PROTOCOL`
- `EFI_IP4_SERVICE_BINDING_PROTOCOL`
- `EFI_TCP4_SERVICE_BINDING_PROTOCOL`
- `EFI_UDP4_SERVICE_BINDING_PROTOCOL`
- `EFI_MTFTP4_SERVICE_BINDING_PROTOCOL`
- `EFI_DHCP4_SERVICE_BINDING_PROTOCOL`
- `EFI_REST_EX_SERVICE_BINDING_PROTOCOL`

Protocol Interface Structure

```
typedef struct _EFI_SERVICE_BINDING_PROTOCOL {
   EFI_SERVICE_BINDING_CREATE_CHILD            CreateChild;
```

(continues on next page)

(continued from previous page)

```
   EFI_SERVICE_BINDING_DESTROY_CHILD           DestroyChild;
}   EFI_SERVICE_BINDING_PROTOCOL;
```

Parameters

CreateChild
Creates a child handle and installs a protocol. See the *EFI_SERVICE_BINDING_PROTOCOL.CreateChild()* function description.

DestroyChild
Destroys a child handle with a protocol installed on it. See the *EFI_SERVICE_BINDING_PROTOCOL.DestroyChild()* function description.

Description

The *EFI_SERVICE_BINDING_PROTOCOL* provides member functions to create and destroy child handles. A driver is responsible for adding protocols to the child handle in *CreateChild()* and removing protocols in *DestroyChild()* . It is also required that the *CreateChild()* function opens the parent protocol BY_CHILD_CONTROLLER to establish the parent-child relationship, and closes the protocol in *DestroyChild()* .The pseudo code for *CreateChild()* and *DestroyChild()* is provided to specify the required behavior, not to specify the required implementation. Each consumer of a software protocol is responsible for calling *CreateChild()* when it requires the protocol and calling *DestroyChild()* when it is finished with that protocol.

11.6.2 EFI_SERVICE_BINDING_PROTOCOL.CreateChild()

Summary

Creates a child handle and installs a protocol.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SERVICE_BINDING_CREATE_CHILD) (
  IN EFI_SERVICE_BINDING_PROTOCOL                  *This,
  IN OUT EFI_HANDLE                                *ChildHandle
);
```

Parameters

This
Pointer to the *EFI_SERVICE_BINDING_PROTOCOL* instance.

ChildHandle
Pointer to the handle of the child to create. If it is a pointer to *NULL* , then a new handle is created. If it is a pointer to an existing UEFI handle, then the protocol is added to the existing UEFI handle.

Description

The *CreateChild()* function installs a protocol on *ChildHandle* . If *ChildHandle* is a pointer to *NULL* , then a new handle is created and returned in *ChildHandle* . If *ChildHandle* is not a pointer to *NULL* , then the protocol installs on the existing *ChildHandle* .

Status Codes Returned

EFI_SUCCESS	The protocol was added to *ChildHandle* .

continues on next page

Table 11.11 – continued from previous page

EFI_INVALID_PARAMETER	*ChildHandle* is *NULL* .
EFI_OUT_OF_RESOURCES	There are not enough resources available to create the child.
Other	The child handle was not created.

Examples

The following example shows how a consumer of the EFI ARP Protocol would use the *CreateChild()* function of the *EFI_SERVICE_BINDING_PROTOCOL* to create a child handle with the EFI ARP Protocol installed on that handle.

```
EFI_HII_HANDLE                      ControllerHandle;
EFI_HANDLE                          DriverBindingHandle;
EFI_HANDLE                          ChildHandle;
EFI_ARP_SERVICE_BINDING_PROTOCOL   *ArpSb;
EFI_ARP_PROTOCOL                   *Arp;

//
// Get the ArpServiceBinding Protocol
//
Status = gBS->OpenProtocol (
        ControllerHandle,
        &gEfiArpServiceBindingProtocolGuid,
        (VOID \**)&ArpSb,
        DriverBindingHandle,
        ControllerHandle,
        EFI_OPEN_PROTOCOL_GET_PROTOCOL
        );
if (EFI_ERROR (Status)) {
  return Status;
}
//
// Initialize a ChildHandle
//
ChildHandle = NULL;
//
// Create a ChildHandle with the Arp Protocol
//
Status = ArpSb->CreateChild (ArpSb, &ChildHandle);
if (EFI_ERROR (Status)) {
  goto ErrorExit;
}

//
// Retrieve the Arp Protocol from ChildHandle
//
Status = gBS->OpenProtocol (
        ChildHandle,
        &gEfiArpProtocolGuid,
        (VOID **)&Arp,
        DriverBindingHandle,
        ControllerHandle,
        EFI_OPEN_PROTOCOL_BY_DRIVER
        );
if (EFI_ERROR (Status)) {
```

(continues on next page)

(continued from previous page)

```
  goto ErrorExit;
}
```

Pseudo Code

The following is the general algorithm for implementing the *CreateChild()* function:

1. Allocate and initialize any data structures that are required to produce the requested protocol on a child handle. If the allocation fails, then return *EFI_OUT_OF_RESOURCES* .
2. Install the requested protocol onto *ChildHandle* . If *ChildHandle* is a pointer to *NULL* , then the requested protocol installs onto a new handle.
3. Open the parent protocol *BY_CHILD_CONTROLLER* to establish the parent-child relationship. If the parent protocol cannot be opened, then destroy the *ChildHandle* created in step 2, free the data structures allocated in step 1, and return an error.
4. Increment the number of children created by *CreateChild()*.
5. Return *EFI_SUCCESS* .

Listed below is sample code of the *CreateChild()* function of the EFI ARP Protocol driver. This driver looks up its private context data structure from the instance of the *EFI_SERVICE_BINDING_PROTOCOL* produced on the handle for the network controller. After retrieving the private context data structure, the driver can use its contents to build the private context data structure for the child being created. The EFI ARP Protocol driver then installs the *EFI_ARP_PROTOCOL* onto *ChildHandle*.

```
EFI_STATUS
EFIAPI
ArpServiceBindingCreateChild (
  IN EFI_SERVICE_BINDING_PROTOCOL *This,
  IN EFI_HANDLE                   *ChildHandle
  )
{
 EFI_STATUS                        Status;
 ARP_PRIVATE_DATA                 *Private;
 ARP_PRIVATE_DATA                 *PrivateChild;

//
// Retrieve the Private Context Data Structure
//
Private = ARP\_PRIVATE_DATA_FROM_SERVICE_BINDING_THIS (This);
//
// Create a new child
//
PrivateChild = EfiLibAllocatePool (sizeof (ARP\_PRIVATE_DATA));
if (PrivateChild == NULL) {
return EFI_OUT_OF_RESOURCES;
}

//
// Copy Private Context Data Structure
//
gBS->CopyMem (PrivateChild, Private, sizeof (ARP\_PRIVATE_DATA));

//
```

(continues on next page)

(continued from previous page)

```
 // Install Arp onto ChildHandle
 //
 Status = gBS->InstallMultipleProtocolInterfaces (
          ChildHandle,
          &gEfiArpProtocolGuid, &PrivateChild->Arp,
          NULL
          );
 if (EFI_ERROR (Status)) {
  gBS->FreePool (PrivateChild);
  return Status;
 }

 Status = gBS->OpenProtocol (
          Private->ChildHandle,
          &gEfiManagedNetworkProtocolGuid,
          (VOID **)&PrivateChild->ManagedNetwork,
          gArpDriverBinding.DriverBindingHandle,
          *ChildHandle,
          EFI_OPEN_PROTOCOL_BY_CHILD_CONTROLLER
          );
 if (EFI_ERROR (Status)) {
  ArpSB->DestroyChild (This, ChildHandle);
  return Status;
 }

 //
 // Increase number of children created
 //
 Private->NumberCreated++;

 return EFI_SUCCESS;
}
```

11.6.3 EFI_SERVICE_BINDING_PROTOCOL.DestroyChild()

Summary

Destroys a child handle with a protocol installed on it.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SERVICE_BINDING_DESTROY_CHILD) (
 IN EFI_SERVICE_BINDING_PROTOCOL             *This,
 IN EFI_HANDLE                               ChildHandle
 );
```

Parameters

This

Pointer to the *EFI_SERVICE_BINDING_PROTOCOL* instance.

ChildHandle
Handle of the child to destroy.

Description

The *DestroyChild()* function does the opposite of *CreateChild()* . It removes a protocol that was installed by *CreateChild()* from *ChildHandle* . If the removed protocol is the last protocol on *ChildHandle* , then *ChildHandle* is destroyed.

Status Codes Returned

EFI_SUCCESS	The protocol was removed from *ChildHandle* .
EFI_UNSUPPORTED	*ChildHandle* does not support the protocol that is being removed.
EFI_INVALID_PARAMETER	*ChildHandle* is not a valid UEFI handle.
EFI_ACCESS_DENIED	The protocol could not be removed from the *ChildHandle* because its services are being used.
Other	The child handle was not destroyed.

Examples

The following example shows how a consumer of the EFI ARP Protocol would use the *DestroyChild()* function of the *EFI_SERVICE_BINDING_PROTOCOL* to destroy a child handle with the EFI ARP Protocol installed on that handle.

```
EFI_HANDLE                          ControllerHandle;
EFI_HANDLE                          DriverBindingHandle;
EFI_HANDLE                          ChildHandle;
EFI_ARP\_SERVICE_BINDING_PROTOCOL   *Arp;

//
// Get the Arp Service Binding Protocol
//
Status = gBS->OpenProtocol (
         ControllerHandle,
         &gEfiArpServiceBindingProtocolGuid,
         (VOID **)&ArpSb,
         DriverBindingHandle,
         ControllerHandle,
         EFI_OPEN_PROTOCOL_GET_PROTOCOL
         );
if (EFI_ERROR (Status)) {
  return Status;
}

//
// Destroy the ChildHandle with the Arp Protocol
//
Status = ArpSb->DestroyChild (ArpSb, ChildHandle);
if (EFI_ERROR (Status)) {
 return Status;
}
```

Pseudo Code

The following is the general algorithm for implementing the *DestroyChild()* function:

1. Retrieve the protocol from *ChildHandle* . If this retrieval fails, then return *EFI_SUCCESS* because the child has already been destroyed.
2. If this call is a recursive call to destroy the same child, then return *EFI_SUCCESS* .
3. Close the parent protocol with *CloseProtocol()* .
4. Set a flag to detect a recursive call to destroy the same child.
5. Remove the protocol from *ChildHandle* . If this removal fails, then reopen the parent protocol and clear the flag to detect a recursive call to destroy the same child.
6. Free any data structures that allocated in *CreateChild()* .
7. Decrement the number of children that created with *CreateChild()* .
8. Return *EFI_SUCCESS* .

Listed below is sample code of the *DestroyChild()* function of the EFI ARP Protocol driver. This driver looks up its private context data structure from the instance of the *EFI_SERVICE_BINDING_PROTOCOL* produced on the handle for the network controller. The driver attempts to retrieve the *EFI_ARP _PROTOCOL* from *ChildHandle* . If that fails, then *EFI_SUCCESS* is returned. The *EFI_ARP _PROTOCOL* is then used to retrieve the private context data structure for the child. The private context data stores the flag that detects if *DestroyChild()* is being called recursively. If a recursion is detected, then *EFI_SUCCESS* is returned. Otherwise, the *EFI_ARP _PROTOCOL* is removed from *ChildHandle*, the number of children are decremented, and *EFI_SUCCESS* is returned.

```
EFI_STATUS
EFIAPI
ArpServiceBindingDestroyChild (
  IN EFI_SERVICE_BINDING_PROTOCOL          *This,
  IN EFI_HANDLE                            ChildHandle
  )
{
EFI_STATUS                                 Status;
EFI_ARP_PROTOCOL                           *Arp;
ARP_PRIVATE_DATA                           *Private;
ARP_PRIVATE_DATA                           *PrivateChild;

//
// Retrieve the Private Context Data Structure
//
Private = ARP\_PRIVATE_DATA_FROM_SERVICE_BINDING_THIS (This);

//
// Retrieve Arp Protocol from ChildHandle
//
Status = gBS->OpenProtocol (
        ChildHandle,
        &gEfiArpProtocolGuid,
        (VOID **)&Arp,
        gArpDriverBinding.DriverBindingHandle,
        ChildHandle,
        EFI_OPEN_PROTOCOL_GET_PROTOCOL
        );
if (EFI_ERROR (Status)) {
  return EFI_SUCCESS;
}
```

(continues on next page)

(continued from previous page)

```
//
// Retrieve Private Context Data Structure
//
PrivateChild = ARP_PRIVATE_DATA_FROM_ARP_THIS (Arp);
if (PrivateChild->Destroy) {
  return EFI_SUCCESS;
}

//
// Close the ManagedNetwork Protocol
//
gBS->CloseProtocol (
    Private-> ChildHandle,
    &gEfiManagedNetworkProtocolGuid,
    gArpDriverBinding.DriverBindingHandle,
    ChildHandle
    );

PrivateChild->Destroy = TRUE;

//
// Uninstall Arp from ChildHandle
//
Status =  gBS->UninstallMultipleProtocolInterfaces (
          ChildHandle,
          &gEfiArpProtocolGuid, &PrivateChild->Arp,
          NULL
          );
if (EFI_ERROR (Status)) {
  //
  // Uninstall failed, so reopen the parent Arp Protocol and
  // return an error
  //
  PrivateChild->Destroy = FALSE;
  gBS->OpenProtocol (
      Private-> ChildHandle,
      &gEfiManagedNetworkProtocolGuid,
      (VOID **)&PrivateChild->ManagedNetwork,
      gArpDriverBinding.DriverBindingHandle,
      ChildHandle,
      EFI_OPEN_PROTOCOL_BY_CHILD_CONTROLLER
      );
  return Status;
}

//
// Free Private Context Data Structure
//
gBS->FreePool (PrivateChild);

//
```

(continues on next page)

(continued from previous page)

```
// Decrease number of children created
//
Private -> NumberCreated --;

return EFI_SUCCESS;
```

11.7 EFI Platform to Driver Configuration Protocol

This section provides a detailed description of the *EFI_PLATFORM_TO_DRIVER_CONFIGURATION_PROTOCOL* . This is a protocol that is optionally produced by the platform and optionally consumed by a UEFI Driver in its *Start()* function. This protocol allows the driver to receive configuration information as part of being started.

11.7.1 EFI_PLATFORM_TO_DRIVER_CONFIGURATION_PROTOCOL

Summary

Used to retrieve configuration information for a device that a UEFI driver is about to start.

GUID

```
#define EFI_PLATFORM_TO_DRIVER_CONFIGURATION_PROTOCOL_GUID \
  { 0x642cd590, 0x8059, 0x4c0a,\
    { 0xa9, 0x58, 0xc5, 0xec, 0x07, 0xd2, 0x3c, 0x4b } }
```

Protocol Interface Structure

```
typedef struct _EFI_PLATFORM_TO_DRIVER_CONFIGURATION_PROTOCOL {
  EFI_PLATFORM_TO_DRIVER_CONFIGURATION_QUERY               Query;
  EFI_PLATFORM_TO_DRIVER_CONFIGURATION_RESPONSE            Response;
}  EFI_PLATFORM_TO_DRIVER_CONFIGURATION_PROTOCOL;
```

Parameters

Query
Called by the UEFI Driver *Start()* function to get configuration information from the platform.

Response
Called by the UEFI Driver *Start()* function to let the platform know how UEFI driver processed the data return from Query.

Description

The EFI_PLATFORM_TO_DRIVER_CONFIGURATION_PROTOCOL is used by the UEFI driver to query the platform for configuration information. The UEFI driver calls *EFI_PLATFORM_TO_DRIVER_CONFIGURATION_PROTOCOL.Query()* multiple times to get configuration information from the platform. For every call to Query() there must be a matching call to *EFI_PLATFORM_TO_DRIVER_CONFIGURATION_PROTOCOL.Response()* so the UEFI driver can inform the platform how it used the information passed in from Query().

It's legal for a UEFI driver to use Response() to inform the platform it does not understand the data returned via Query() and thus no action was taken.

11.7.2 EFI_PLATFORM_TO_DRIVER_CONFIGURATION_PROTOCOL.Query()

Summary

Allows the UEFI driver to query the platform for configuration information needed to complete the drivers *Start()* operation.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PLATFORM_TO_DRIVER_CONFIGURATION_QUERY) (
  IN EFI_PLATFORM_TO_DRIVER_CONFIGURATION_PROTOCOL    *This,
  IN EFI_HANDLE                                       ControllerHandle,
  IN EFI_HANDLE                                       ChildHandle OPTIONAL,
  IN UINTN                                            *Instance,
  OUT EFI_GUID                                        **ParameterTypeGuid,
  OUT VOID                                            **ParameterBlock,
  OUT UINTN                                           *ParameterBlockSize
  );
```

Parameters

This
A pointer to the *EFI_PLATFORM_TO_DRIVER_CONFIGURATION_PROTOCOL* instance.

ControllerHandle
The handle the platform will return configuration information about.

ChildHandle
The handle of the child controller to return information on. This is an optional parameter that may be NULL. It will be NULL for device drivers, and for bus drivers that attempt to get options for the bus controller. It will not be NULL for a bus driver that attempts to get options for one of its child controllers.

Instance
Pointer to the Instance value. Zero means return the first query data. The caller should increment this value by one each time to retrieve successive data.

ParameterTypeGuid
An *EFI_GUID* that defines the contents of ParameterBlock. UEFI drivers must use the ParameterTypeGuid to determine how to parse the ParameterBlock.The caller should not attempt to free *ParameterTypeGuid* .

ParameterBlock
The platform returns a pointer to the *ParameterBlock* structure which contains details about the configuration parameters specific to the *ParameterTypeGuid* . This structure is defined based on the protocol and may be different for different protocols. UEFI driver decodes this structure and its contents based on *ParameterTypeGuid* . *ParameterBlock* is allocated by the platform and the platform is responsible for freeing the *ParameterBlock* after *Response* is called.

ParameterBlockSize
The platform returns the size of the ParameterBlock in bytes.

Description

The UEFI driver must call Query early in the *Start()* function before any time consuming operations are performed. If ChildHandle is NULL the driver is requesting information from the platform about the ControllerHandle that is being started. Information returned from Query may lead to the drivers *Start()* function failing.

If the UEFI driver is a bus driver and producing a ChildHandle the driver must call Query after the child handle has been created and an EFI_DEVICE_PATH_PROTOCOL has been placed on that handle, but before any time consuming operation is performed. If information return by *Query* may lead the driver to decide to not create the ChildHandle. The driver must then cleanup and remove the ChildHandle from the system.

The UEFI driver repeatedly calls Query, processes the information returned by the platform, and calls Response passing in the arguments returned from Query. The *Instance* value passed into Response must be the same value passed to the corresponding call to Query. The UEFI driver must continuously call Query and Response until EFI_NOT_FOUND is returned by Query.

If the UEFI driver does not recognize the *ParameterTypeGuid* , it calls *Response* with a *ConfigurationAction* of *EfiPlatformConfigurationActionUnsupportedGuid* . The UEFI driver must then continue calling *Query* and *Response* until *EFI_NOT_FOUND* is returned by *Query*. This gives the platform an opportunity to pass additional configuration settings using a different *ParameterTypeGuid* that may be supported by the driver.

An *Instance* value of zero means the first *ParameterBLock* in the set of unprocessed parameter blocks. The driver should increment the *Instance* value by one for each successive call to *Query* .

Status Codes Returned

EFI_SUCCESS	The platform return parameter information for ControllerHandle.
EFI_NOT_FOUND	No more unread Instance exists.
EFI_INVALID_PARAMETER	ControllerHandle is *NULL* .
EFI_INVALID_PARAMETER	*Instance* is NULL.
EFI_DEVICE_ERROR	A device error occurred while attempting to return parameter block information for the controller specified by ControllerHandle and ChildHandle.
EFI_OUT_RESOURCES	There are not enough resources available to set the configuration options for the controller specified by ControllerHandle and ChildHandle.

11.7.3 EFI_PLATFORM_TO_DRIVER_CONFIGURATION_PROTOCOL.Response()

Summary

Tell the platform what actions where taken by the driver after processing the data returned from Query.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PLATFORM_TO_DRIVER_CONFIGURATION_RESPONSE) (
  IN EFI_PLATFORM_TO_DRIVER_CONFIGURATION_PROTOCOL     *This,
  IN EFI_HANDLE                                        ControllerHandle,
  IN EFI_HANDLE                                        ChildHandle OPTIONAL,
  IN UINTN                                             *Instance,
  IN EFI_GUID                                          *ParameterTypeGuid,
  IN VOID                                              *ParameterBlock,
  IN UINTN                                             ParameterBlockSize,
  IN EFI_PLATFORM_CONFIGURATION_ACTION                 ConfigurationAction
  );
```

Parameters

This

A pointer to the *EFI_PLATFORM_TO_DRIVER_CONFIGURATION_PROTOCOL* instance.

ControllerHandle

The handle the driver is returning configuration information about.

ChildHandle

The handle of the child controller to return information on. This is an optional parameter that may be NULL. It will be NULL for device drivers, and for bus drivers that attempt to get options for the bus controller. It will not be NULL for a bus driver that attempts to get options for one of its child controllers.

Instance

Instance data passed to *EFI_PLATFORM_TO_DRIVER_CONFIGURATION_PROTOCOL.Query()* .

ParameterTypeGuid

ParameterTypeGuid returned from Query.

ParameterBlock

ParameterBlock returned from Query.

ParameterBlockSize

The ParameterBlock size returned from Query.

ConfigurationAction

The driver tells the platform what action is required for ParameterBlock to take effect. See "Related Definitions" for a list of actions.

Description

The UEFI driver repeatedly calls Query, processes the information returned by the platform, and calls Response passing in the arguments returned from Query. The UEFI driver must continuously call Query until EFI_NOT_FOUND is returned. For every call to Query that returns EFI_SUCCESS a corresponding call to Response is required passing in the same ContollerHandle, ChildHandle, Instance, ParameterTypeGuid, ParameterBlock, and ParameterBlockSize. The UEFI driver may update values in ParameterBlock based on rules defined by ParameterTypeGuid.

The platform is responsible for freeing ParameterBlock and the UEFI driver must not try to free it.

Related Definitions

```
typedef enum {
  EfiPlatformConfigurationActionNone              = 0,
  EfiPlatformConfigurationActionStopController    = 1,
  EfiPlatformConfigurationActionRestartController = 2,
  EfiPlatformConfigurationActionRestartPlatform   = 3,
  EfiPlatformConfigurationActionNvramFailed       = 4,
  EfiPlatformConfigurationActionUnsupportedGuid   = 5,
  EfiPlatformConfigurationActionMaximum
} EFI_PLATFORM_CONFIGURATION_ACTION;
```

EfiPlatformConfigurationActionNone

The controller specified by *ControllerHandle* is still in a usable state, it's configuration has been updated via parsing the *ParameterBlock* . If required by the parameter block and the module supports an NVRAM store the configuration information from *ParameterBlock* was successfully saved to the NVRAM. No actions are required before this controller can be used again with the updated configuration settings.

EfiPlatformConfigurationStopController

The driver has detected that the controller specified by *ControllerHandle* is not in a usable state, and it needs to be stopped. The calling agent can use the *EFI_BOOT_SERVICES.DisconnectController()* service to perform this operation, and it should be performed as soon as possible.

EfiPlatformConfigurationRestartController

This controller specified by *ControllerHandle* needs to be stopped and restarted before it can be used again. The calling agent can use the *DisconnectController()* and *EFI_BOOT_SERVICES.ConnectController()* services to perform this operation. The restart operation can be delayed until all of the configuration options have been set.

EfiPlatformConfigurationRestartPlatform

A configuration change has been made that requires the platform to be restarted before the controller specified by *ControllerHandle* can be used again. The calling agent can use the *ResetSystem()* services to perform this operation. The restart operation can be delayed until all of the configuration options have been set.

EfiPlatformConfigurationActionNvramFailed

The controller specified by *ControllerHandle* is still in a usable state; its configuration has been updated via parsing the *ParameterBlock* . The driver tried to update the driver's private NVRAM store with information from *ParameterBlock* and failed. No actions are required before this controller can be used again with the updated configuration settings, but these configuration settings are not guaranteed to persist after *ControllerHandle* is stopped.

EfiPlatformConfigurationActionUnsupportedGuid

The controller specified by ControllerHandle is still in a usable state; its configuration has not been updated via parsing the ParameterBlock. The driver did not support the ParameterBlock format identified by ParameterTypeGuid. No actions are required before this controller can be used again. On additional Query calls from this *ControllerHandle* , the platform should stop returning a ParameterBlock qualified by this same ParameterTypeGuid. If no other ParameterTypeGuid is supported by the platform, Query should return EFI_NOT_FOUND.

Status Codes Returned

EFI_SUCCESS	The platform return parameter information for ControllerHandle.
EFI_NOT_FOUND	Instance was not found.
EFI_INVALID_PARAMETER	ControllerHandle is *NULL* .

11.7.4 DMTF SM CLP ParameterTypeGuid

The following parameter protocol ParameterTypeGuid provides the support for parameters communicated through the DMTF SM CLP Specification 1.0 Final Standard to be used to configure the UEFI driver.

In this section the producer of the EFI_PLATFORM_TO_DRIVER_CONFIGURATION_PROTOCOL is platform firmware and the consumer is the UEFI driver.

Note: *If future versions of the DMTF SM CLP Specification require changes to the parameter block definition, newer ParameterTypeGuid will be used.*

GUID

```
#define EFI_PLATFORM_TO_DRIVER_CONFIGURATION_CLP_GUID \
 {0x345ecc0e, 0xcb6, 0x4b75, \
   {0xbb, 0x57, 0x1b, 0x12, 0x9c, 0x47, 0x33,0x3e}}
```

Parameter Block

```
typedef struct {
  CHAR8                 *CLPCommand;
  UINT32                CLPCommandLength;
  CHAR8                 *CLPReturnString;*
  UINT32                CLPReturnStringLength;
  UINT8                 CLPCmdStatus;
  UINT8                 CLPErrorValue;
  UINT16                CLPMsgCode;
} EFI_CONFIGURE_CLP_PARAMETER_BLK;
```

Structure Member Definitions

CLPCommand

A pointer to the null-terminated UTF-8 string that specifies the DMTF SM CLP command line that the driver is required to parse and process when this function is called. See the *DMTF SM CLP Specification 1.0* Final Standard for details on the format and syntax of the CLP command line string. *CLPCommand* buffer is allocated by the producer of the EFI_PLATFORM_TO_DRIVER_CONFIGURATION_PROTOCOL.

CLPCommandLength

The length of the CLP Command in bytes.

CLPReturnString

A pointer to the null-terminated UTF-8 string that indicates the CLP return status that the driver is required to provide to the calling agent. The calling agent may parse and/or pass this for processing and user feedback. The SM CLP Command Response string buffer is filled in by the UEFI driver in the "keyword=value" format described in the SM CLP Specification (see section 3.table 101, "Output Data"), unless otherwise requested via the SM CLP -output option in the Command Line string buffer. UEFI driver's support for this default "keyword=value" output format is required if the UEFI driver supports this protocol, while support for other SM CLP output formats is optional. (The UEFI Driver should set CLPCmdStatus=2 (COMMAND PROCESSING FAILED) and CLPErrorValue=249 (OUTPUT FORMAT NOT SUPPORTED) if the SM CLP -output option requested by the caller is not supported by the UEFI Driver.).

CLPReturnString* buffer is allocated by the consumer of the EFI_PLATFORM_TO_DRIVER _CONFIGURATION_PROTOCOL and undefined prior to the call to *Response* ().

CLPReturnStringLength

The length of the CLP return status string in bytes.

CLPCmdStatus

SM CLP Command Status (see *DMTF SM CLP Specification 1.0* Final Standard - Table 4)

CLPErrorValue

SM CLP Processing Error Value (see DMTF SM CLP Specification 1.0 Final Standard - Table 6).

This field is filled in by the consumer of the *EFI_PLATFORM_TO_DRIVER_CONFIGURATION_PROTOCOL* and undefined prior to the call to *Response()*.

CLPMsgCode

Bit 15: OEM Message Code Flag

0 = Message Code is an SM CLP Probable Cause Value. (see SM CLP Specification Table 11)

Bits 14-0: Message Code

This field is filled in by the consumer of the *EFI_PLATFORM_TO_DRIVER_CONFIGURATION_PROTOCOL* and undefined prior to the call to *Response()*.

11.8 EFI Driver Supported EFI Version Protocol

11.8.1 EFI_DRIVER_SUPPORTED_EFI_VERSION_PROTOCOL

Summary

Provides information about the version of the EFI specification that a driver is following. This protocol is required for EFI drivers that are on PCI and other plug in cards.

GUID

```
#define EFI_DRIVER_SUPPORTED_EFI_VERSION_PROTOCOL_GUID \
 { 0x5c198761, 0x16a8, 0x4e69, \
  { 0x97, 0x2c, 0x89, 0xd6, 0x79, 0x54, 0xf8, 0x1d } }
```

Protocol Interface Structure

```
typedef struct _EFI_DRIVER_SUPPORTED_EFI_VERSION_PROTOCOL {
  UINT32                Length;
  UINT32                FirmwareVersion;
} EFI_DRIVER_SUPPORTED_EFI_VERSION_PROTOCOL;
```

Parameters

Length

The size, in bytes, of the entire structure. Future versions of this specification may grow the size of the structure.

FirmwareVersion

The latest version of the UEFI Specification that this driver conforms to. Refer to the *EFI_SPECIFICATION_VERSION* definition in *EFI System Table*.

Description

The *EFI_DRIVER_SUPPORTED_EFI_VERSION_PROTOCOL* provides a mechanism for an EFI driver to publish the version of the EFI specification it conforms to. This protocol must be placed on the drivers image handle when the driver's entry point is called.

11.9 EFI Driver Family Override Protocol

11.9.1 Overview

This section defines the Driver Family Override Protocol, and contains the following:

- Description and code definitions of the Driver Family Override Protocol.
- Required updates to the EFI Boot Services ConnectController().
- Typical production of the Driver Family Override Protocol by an EFI Driver that follows the EFI Driver Model.

The Driver Family Override Protocol provides a method for an EFI Driver to opt-in to a higher priority rule for connecting drivers to controllers in the EFI Boot Service *ConnectController()* . This new rule is higher priority than the Bus Specific Driver Override Protocol rule and lower priority than the Platform Driver Override Rule.

The Driver Family Override Protocol is a backwards compatible extension to the EFI Driver Model and is only available during boot time. The Driver Family Override Protocol may be optionally produced by a driver that follows the EFI Driver Model. If this protocol is produced, it must be installed onto the Driver Image Handle. Drivers that follow the EFI Driver Model typically install the EFI Driver Binding Protocol onto the driver's image handle. In this case, the Driver Family Override Protocol must also be installed onto the driver's image handle. If a single EFI Driver produces more than one instance of the EFI Driver Binding Protocol, then the Driver Family Override Protocol must be installed onto the same handle as the EFI Driver Binding Protocol that is associated with the Driver Family Override Protocol. Since it is legal for a single EFI Driver to produce multiple EFI Driver Binding Protocol instances, it is also legal for a single EFI Driver to produce multiple Driver Family Override Protocol instances.

11.9.1.1 EFI_DRIVER_FAMILY_OVERRIDE_PROTOCOL

Summary

When installed, the Driver Family Override Protocol informs the UEFI Boot Service *ConnectController()* that this driver is higher priority than the list of drivers returned by the Bus Specific Driver Override Protocol.

GUID

```
#define EFI_DRIVER_FAMILY_OVERRIDE_PROTOCOL_GUID \
 {0xb1ee129e,0xda36,0x4181,\
  {0x91,0xf8,0x04,0xa4,0x92,0x37,0x66,0xa7}}
```

Protocol Interface Structure

```
typedef struct \_EFI_DRIVER_FAMILY_OVERRIDE_PROTOCOL {
  EFI_DRIVER_FAMILY_OVERRIDE_GET_VERSION        GetVersion;
}  EFI_DRIVER_FAMILY_OVERRIDE_PROTOCOL;
```

Parameters

GetVersion

Retrieves the version of the driver that is used by the EFI Boot Service *ConnectController()* to sort the set of Driver Binding Protocols in order from highest priority to lowest priority. For drivers that support the Driver Family Override Protocol, those drivers are sorted so that the drivers with higher values returned by *GetVersion()* are high priority that drivers that return lower values from *GetVersion()* .

Description

This protocol contains a single service that returns a version value for the driver that produces this protocol. High values are higher priority than lower values when evaluated by the EFI Boot Service *ConnectController()* . This is an optional protocol that may be produced by an EFI Driver that follows the EFI Driver Model. If this protocol is produced, it must be installed onto a handle that also contains the EFI Driver Binding Protocol.

If this protocol is not produced by an EFI Driver, then the rules used to connect a driver to a controller from highest priority to lowest priority are as follows:

- Context Override
- Platform Driver Override
- Bus Specific Driver Override Protocol
- Driver Binding Search

If this protocol is produced by an EFI Driver, then the rules used to connect a driver to a controller from highest priority to lowest priority are as follows:

- Context Override
- Platform Driver Override
- Driver Family Override
- Bus Specific Driver Override
- Driver Binding Search

11.9.1.2 EFI_DRIVER_FAMILY_OVERRIDE_PROTOCOL.GetVersion()

Summary

Retrieves the version of the driver that is used by the EFI Boot Service *ConnectController()* to sort the set of Driver Binding Protocols in order from highest priority to lowest priority. For drivers that support the Driver Family Override Protocol, those drivers are sorted so that the drivers with higher values returned by *GetVersion()* are high priority that drivers that return lower values from *GetVersion()* .

Prototype

```
typedef
UINT32
(EFIAPI *EFI_DRIVER_FAMILY_OVERRIDE_GET_VERSION) (
  IN EFI_DRIVER_FAMILY_OVERRIDE_PROTOCOL     *This
  );
```

Parameters

This A pointer to the *EFI_DRIVER_FAMILY_OVERRIDE_PROTOCOL* instance.

Description

This function returns the version value associated with the driver specified by *This*.

11.10 EFI Driver Health Protocol

This section contains the basic definitions of the Driver Health Protocol.

11.10.1 EFI_DRIVER_HEALTH_PROTOCOL

Summary

When installed, the Driver Health Protocol produces a collection of services that allow the health status for a controller to be retrieved. If a controller is not in a usable state, status messages may be reported to the user, repair operations can be invoked, and the user may be asked to make software and/or hardware configuration changes. All display, as well as interaction, with the user must be handled by the consumer of the Driver Health Protocol.

The Driver Health Protocol must be installed onto the same handle as the associated Driver Binding handle.

GUID

```
#define EFI_DRIVER_HEALTH_PROTOCOL_GUID \
 {0x2a534210,0x9280,0x41d8,\
  {0xae,0x79,0xca,0xda,0x01,0xa2,0xb1,0x27 }}
```

Protocol Interface Structure

```
typedef struct _EFI_DRIVER_HEALTH_PROTOCOL {
 EFI_DRIVER_HEALTH_GET_HEALTH_STATUS       GetHealthStatus;
   EFI_DRIVER_HEALTH_REPAIR                Repair;
} EFI_DRIVER_HEALTH_PROTOCOL;
```

Parameters

GetHealthStatus

Retrieves the health status of a controller in the platform. This function can also optionally return warning messages, error messages, and an HII Form that may be used to repair a controller that is not properly configured.

Repair

Performs a repair operation on a controller in the platform. This function can optionally report repair progress information back to the platform.

Description

The Driver Health Protocol is optionally produced by a driver that follows the EFI Driver Model. If an EFI Driver needs to report health status to the platform, provide warning or error messages to the user, perform length repair operations, or request the user to make hardware or software configuration changes, then the Driver Health Protocol must be produced.

A controller that is managed by driver that follows the EFI Driver Model and produces the Driver Health Protocol must report the current health of the controllers that the driver is currently managing. The controller can initially be healthy, failed, require repair, or require configuration. If a controller requires configuration, and the user make configuration changes, the controller may then need to be reconnected or the system may need to be rebooted for the configuration changes to take effect. Figure 2-1 below shows all the possible health states of a controller, the set of initial states, the set of terminal states, and the legal transitions between the health states.

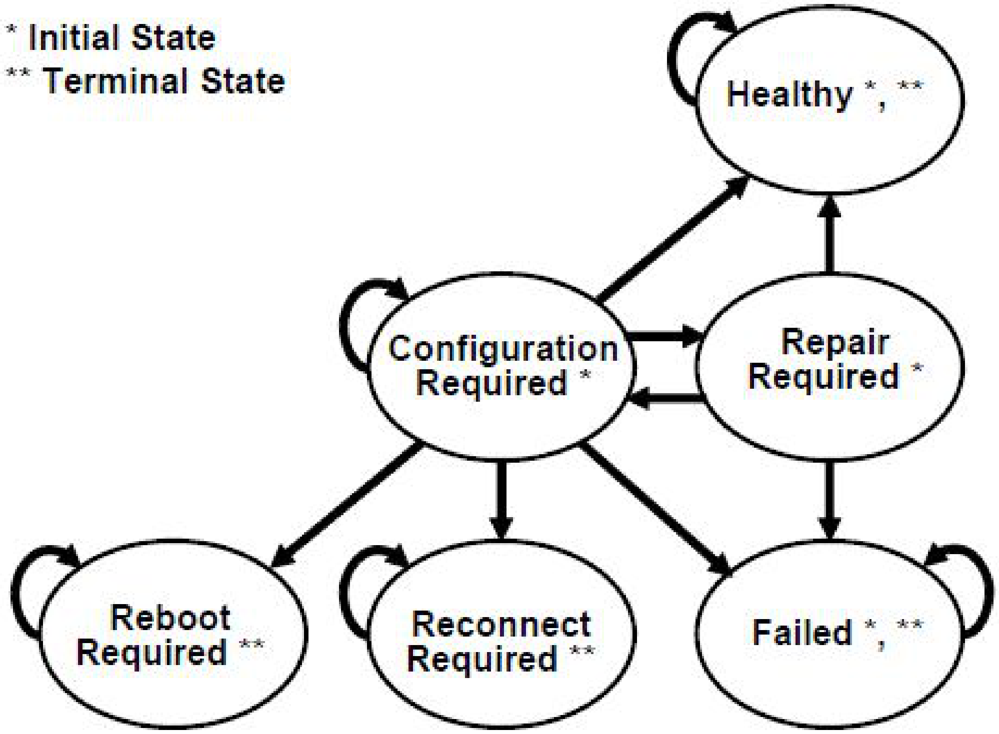

Fig. 11.1: Driver Health Status States

11.10.2 EFI_DRIVER_HEALTH_PROTOCOL.GetHealthStatus()

Summary

Retrieves the health status of a controller in the platform. This function can also optionally return warning messages, error messages, and an HII Form that may be used to repair a controller that is not proper configured.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_DRIVER_HEALTH_GET_HEALTH_STATUS) (
  IN EFI_DRIVER_HEALTH_PROTOCOL          *This,
  IN EFI_HANDLE                          ControllerHandle, OPTIONAL
  IN EFI_HANDLE                          ChildHandle, OPTIONAL
  OUT EFI_DRIVER_HEALTH_STATUS           *HealthStatus,
  OUT EFI_DRIVER_HEALTH_HII_MESSAGE      **MessageList, OPTIONAL
  OUT EFI_HII_HANDLE                     *FormHiiHandle OPTIONAL
  );
```

Parameters

This
A pointer to the *EFI_DRIVER_HEALTH_PROTOCOL* instance.

ControllerHandle
The handle of the controller to retrieve the health status on. This is an optional parameter that may be *NULL* . If this parameter is *NULL* , then the value of *ChildHandle* is ignored, and the combined health status of all the devices that the driver is managing is returned.

ChildHandle
The handle of the child controller to retrieve the health status on. This is an optional parameter that may be NULL. It will be NULL for device drivers. It will also be NULL for bus drivers when an attempt is made to collect the health status of the bus controller. If will not be NULL when an attempt is made to collect the health status for a child controller produced by the driver. If ControllerHandle is NULL, then this parameter is ignored.

HealthStatus
A pointer to the health status that is returned by this function. The health status for the controller specified by *ControllerHandle* and *ChildHandle* is returned.

MessageList
A pointer to an array of warning or error messages associated with the controller specified by *ControllerHandle* and *ChildHandle* . This is an optional parameter that may be *NULL* . *MessageList* is allocated by this function with the EFI Boot Service *AllocatePool()* , and it is the caller's responsibility to free *MessageList* with the EFI Boot Service *FreePool()* . Each message is specified by tuple of an *EFI_HII_HANDLE* and an *EFI_STRING_ID* . The array of messages is terminated by tuple containing a EFI_HII_HANDLE with a value of *NULL* . The *EFI_HII_STRING_PROTOCOL.GetString()* function can be used to retrieve the warning or error message as a Null-terminated string in a specific language. Messages may be returned for any of the *HealthStatus* values except *EfiDriverHealthStatusReconnectRequired* and *EfiDriverHealthStatusRebootRequired* .

FormHiiHandle
A pointer to the HII handle containing the HII form used when configuration is required. The HII handle is associated with the controller specified by *ControllerHandle* and *ChildHandle* . If this is *NULL* , then no HII form is available. An HII handle will only be returned with a *HealthStatus* value of E *fiDriverHealthStatusConfigurationRequired* .

Description

This function returns the health status associated with the controller specified by *ControllerHandle* and *ChildHandle*. If ControllerHandle is NULL, and if the EFI driver is not managing any controller then EFI_UNSUPPORTED is returned. If *ControllerHandle* is not *NULL* and the driver specified by *This* is not currently managing the controller specified by *ControllerHandle* and *ChildHandle* , then *EFI_UNSUPPORTED* is returned. If *HealthStatus* is *NULL* , then *EFI_INVALID_PARAMETER* is returned.

If *ControllerHandle* is *NULL* , then the cumulative health status of all the controllers managed by the EFI driver is returned. If all the controller manages by the driver are healthy, then *EfiDriverHealthStatusHealthy* must be returned in *HealthStatus* . If one or more of the controllers managed by the EFI Driver is not healthy, then *EfiDriverHealthStatusFailed* must be returned.

If *ControllerHandle* is not *NULL* and *ChildHandle* is *NULL* , then the health status of the controller specified by *ControllerHandle* is returned in *HealthStatus* and *EFI_SUCCESS* is returned.

If *ControllerHandle* is not *NULL* and *ChildHandle* is not *NULL* , then the health status of the child controller specified by *ControllerHandle* and *ChildHandle* is returned in *HealthStatus* and *EFI_SUCCESS* is returned.

If *MessageList* is *NULL* , then no messages are returned from this function.

If *MessageList* is not *NULL* , and *HealthStatus* is *EfiDriverHealthStatusReconnectRequired* or *EfiDriverHealthStatus-RebootRequired* then no messages are returned and **MessageList* must be set to *NULL* .

If *MessageList* is not *NULL* , and there are no warning or error messages associated with the controller specified by *ControllerHandle* and *ChildHandle* , then **MessageList* must be set to *NULL* .

If *MessageList* is not *NULL* , and there are one or more warning or error messages associated with the controller specified by *ControllerHandle* and *ChildHandle* , then **MessageList* must point to a buffer allocated with the EFI Boot Service *AllocatePool()* . The number of *EFI_DRIVER_HEALTH_HII_MESSAGE* structures allocated in the buffer must be one more than the total number of warning or error messages, and the *HiiHandle* field of the last *EFI_DRIVER_HEALTH_HII_MESSAGE* structure must be set to *NULL* to terminate the list of messages. It is the caller's responsibility to free the buffer returned in **MessageList* using the EFI Boot Service *FreePool()* . Each message is specified by an *EFI_HII_HANDLE* and an *EFI_STRING_ID* . The caller may use the *EFI_HII_STRING_PROTOCOL.GetString()* function to convert each message into a Null-terminated string that can may be displayed on a console device.

If *FormHiiHandle* is *NULL* , then no forms are returned from this function.

If *FormHiiHandle* is not *NULL* , and *HealthStatus* is not *EfiDriverHealthStatusConfigurationRequired* , then no forms are returned and **FormHiiHandle* must be set to *NULL* .

If *FormHiiHandle* is not *NULL* , and *FormSetGuid* is not *NULL* , and *HealthStatus* is *EfiDriverHealthStatusConfigurationRequired* , then *FormHiiHandle* is assigned to the HII handle which contains the HII form required to perform the configuration operation.

If ControllerHandle is NULL, and there are no devices being managed by the driver then EFI_UNSUPPORTED is returned.

Related Definitions

```
//*******************************************************
// EFI_DRIVER_HEALTH_STATUS
//*******************************************************
typedef enum {
   EfiDriverHealthStatusHealthy,
   EfiDriverHealthStatusRepairRequired,
   EfiDriverHealthStatusConfigurationRequired,
   EfiDriverHealthStatusFailed,
   EfiDriverHealthStatusReconnectRequired,
   EfiDriverHealthStatusRebootRequired
 }  EFI_DRIVER_HEALTH_STATUS;
```

EfiDriverHealthStatusHealthy

The controller is in a healthy state.

EfiDriverHealthStatusRepairRequired

The controller requires a repair operation that will take an extended period of time to perform. The EFI Boot Manager is required to call the *Repair()* function when this state is detected. After the *Repair()* function completed, the health status may be *EfiDriverHealthStatusHealthy* , *EfiDriverHealthStatusConfigurationRequired* , or *EfiDriverHealthStatusFailed* .

EfiDriverHealthStatusConfigurationRequired

The controller requires the user to make software or hardware configuration changes in order to put the controller into a healthy state. The set of software configuration changes are specified by the FormHiiHandle and FormSetGuid parameters. The EFI Boot Manager may call the EFI_FORM_BROWSER2_PROTOCOL.SendForm() function to display configuration information and allow the user to make the required configuration changes. The HII form is the first enabled form in the form set class *EFI_HII_DRIVER_HEALTH_FORMSET_GUID* , which is installed on the returned HII handle *FormHiiHandle* . The *MessageList* parameter may be used to identify additional user configuration operations required to place the controller in a healthy state. After the *FormHiiHandle* and *MessageList* have been processed by the EFI Boot Manager, the health status may be *EfiDriverHealthStatusHealthy* ,

EfiDriverHealthStatusConfigurationRequired ,
EfiDriverHealthStatusRepairRequired ,
EfiDriverHealthStatusFailed ,
EfiDriverHealthStatusReconnectRequired , or
EfiDriverHealthStatusRebootRequired .

EfiDriverHealthStatusFailed

The controller is in a failed state, and there no actions that can place the controller into a healthy state. This controller can not be used as a boot device and no boot devices behind this controller can be used as a boot device.

EfiDriverHealthStatusReconnectRequired

A hardware and/or software configuration changewas performed by the user, and the controller needs to bereconnected before the controller can be placed in ahealthy state. The EFI Boot Manager is required to callthe EFI Boot Service DisconnectController() followed bythe EFI Boot Service ConnectController() to reconnect thecontroller.

EfiDriverHealthStatusRebootRequired

A hardware and/or software configuration change was performed by the user, and the controller requires the entire platform to be rebooted before the controller can be placed in a healthy state. The EFI Boot Manager should complete the configuration and repair operations on all the controllers that are not in a healthy state before rebooting the system.

```
//*******************************************************
// EFI_DRIVER_HEALTH_HII_MESSAGE
//*******************************************************
typedef struct {
 EFI_HII_HANDLE HiiHandle;
 EFI_STRING_ID StringId;
 UINT64 MessageCode;
} EFI_DRIVER_HEALTH_HII_MESSAGE;
```

HiiHandle

The *EFI_HII_HANDLE* that was returned by *EFI_HII_DATABASE_PROTOCOL.NewPackageList()* when the string pack containing StringId was registered with the HII Database.

StringId

The identifier for a single string token in the string pack associated with *HiiHandle*.

MessageCode

64-bit numeric value of the warning/error specified by this message. A value of *0x0000000000000000* is used to indicate that *MessageCode* is not specified.

The values *0x0000000000000001* to *0x0fffffffffffffff* are reserved for allocation by the UEFI Specification.

The values *0x1000000000000000* to *0x1fffffffffffffff* are reserved for IHV-developed drivers.

The values *0x8000000000000000* to *0x8fffffffffffffff* is reserved for platform/OEM drivers.

All other values are reserved and should not be used.

Status Codes Returned

EFI_SUCCESS	The health status of the controller specified by ControllerHandle and ChildHandle was returned in HealthStatus. A list of warning and error messages may be optionally returned in MessageList, and an HII Form may be optionally specified by FormHiiHandle.
EFI_UNSUPPORTED	ControllerHandle is not NULL, and the controller specified by ControllerHandle and ChildHandle is not currently being managed by the driver specified by This.
EFI_UNSUPPORTED	ControllerHandle is NULL and there are no devices being managed by the driver.
EFI_INVALID_PARAMETER	HealthStatus is NULL.
EFI_OUT_OF_RESOURCES	MessageList is not NULL, and there are not enough resource available to allocate memory for MessageList.

11.10.3 EFI_DRIVER_HEALTH_PROTOCOL.Repair()

Summary

Performs a repair operation on a controller in the platform. This function can optionally report repair progress information back to the platform.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_DRIVER_HEALTH_REPAIR) (
 IN EFI_DRIVER_HEALTH_PROTOCOL              *This,
 IN EFI_HANDLE                              ControllerHandle,
 IN EFI_HANDLE                              ChildHandle OPTIONAL,
 IN EFI_DRIVER_HEALTH_REPAIR_NOTIFY         RepairNotify OPTIONAL
 );
```

Parameters

This

A pointer to the *EFI_DRIVER_HEALTH_PROTOCOL* instance.

ControllerHandle

The handle of the controller to repair.

ChildHandle

The handle of the child controller to repair. This is an optional parameter that may be *NULL* . It will be *NULL* for device drivers. It will also be *NULL* for bus drivers when an attempt is made to repair a bus controller. If will not be *NULL* when an attempt is made to repair a child controller produced by the driver.

RepairNotify

A notification function that may be used by a driver to report the progress of the repair operation. This is an optional parameter that may be *NULL* .

Description

This function repairs the controller specified by *ControllerHandle* and *ChildHandle* . If the driver specified by *This* is not currently managing the controller specified by *ControllerHandle* and *ChildHandle* , then *EFI_UNSUPPORTED* is returned. If there are not enough resource available to complete the repair operation, then *EFI_OUT_OF_RESOURCES* is returned. Otherwise, *EFI_SUCCESS* is returned. A return value of *EFI_SUCCESS* does not guarantee that the controller is in a healthy state. The EFI Boot Manager must call the *GetHealthStatus()* function to determine the result of the repair operation.

If *RepairNotify* is not *NULL* , and the repair operation requires an extended period of time to execute, then the driver performing the repair operation may intermittently call the *RepairNotify* function to inform the EFI Boot Manager of the progress of the repair operation. The *RepairNotify* function take two parameters to specify the current progress value and the limit value. These two values may be used by the EFI Boot Manager to present status information for the current repair operation.

Related Definitions

```
//*******************************************************
// EFI_DRIVER_HEALTH_REPAIR_NOTIFY
//*******************************************************
typedef
EFI_STATUS
(EFIAPI *EFI_DRIVER_HEALTH_REPAIR_NOTIFY) (
 IN UINTN                               Value,
 IN UINTN                               Limit
 );
```

Value

A value between 0 and Limit that identifies the current progress of the repair operation.

Limit

The maximum value of Value for the current repair operation. If Limit is 0, then the completion progress is indeterminate. For example, a driver that wants to specify progress in percent would use a Limit value of 100.

Status Codes Returned

EFI_SUCCESS	An attempt to repair the controller specified by ControllerHandle and ChildHandle was performed. The result of the repair operation can bet determined by calling GetHealthStatus().
EFI_UNSUPPORTED	The driver specified by This is not currently managing the controller specified by ControllerHandle and ChildHandle.
EFI_OUT_OF_RESOURCES	There are not enough resources to perform the repair operation.

11.10.4 UEFI Boot Manager Algorithms

This section contains example algorithms that a UEI Boot Manager or UEFI Application could use to interact with one or more instances of the EFI Driver Health Protocol present in the platform.

11.10.4.1 All Controllers Healthy

This section contains example algorithms that a UEFI Boot Manager or UEFI Application could use to interact with one or more instances of the EFI Driver Health Protocol present in the platform.

The following algorithm collects all the EFI Driver Health Protocols currently present in the EFI Handle Database, and queries each EFI Driver Health Protocol to determine if one or more of the controllers managed by each EFI Driver Health Protocol instance are not healthy. The variable *AllHealthy* is *TRUE* if all the controllers in the platform are healthy. *AllHealthy* is *FALSE* if one of more of the controllers in the platform are not healthy.

```
EFI_STATUS                   Status;
UINTN                        NoHandles;
EFI_HANDLE                   *Handles;
UINTN                        Index;
EFI_DRIVER_HEALTH_PROTOCOL   *DriverHealth;
BOOLEAN                      AllHealthy;

Status = gBS->LocateHandleBuffer (
         ByProtocol,
         &gEfiDriverHealthProtocolGuid,
         NULL,
         &NoHandles,
         &Handles
         );
if (EFI_ERROR (Status)) {
  return;
}

AllHealthy = TRUE;
for (Index = 0; Index < NoHandles; Index++) {
 Status = gBS->HandleProtocol (
         Handles[Index],
         &gEfiDriverHealthProtocolGuid,
         (VOID \  )&DriverHealth
         );
 if (!EFI_ERROR (Status)) {
  Status = DriverHealth->GetHealthStatus (
               DriverHealth,
               NULL,
               NULL,
               NULL,
               NULL,
               NULL,
               NULL
               );
  if (EFI_ERROR (Status)) {
   AllHealthy = FALSE;
  }
```

(continues on next page)

(continued from previous page)

```
 }
}
```

11.10.4.2 Process a Controller Until Terminal StateReached

The following algorithm processes a single controller using the EFI Driver Health Protocol associated with that controller. This algorithm continues to query the *GetHealthStatus()* service until one of the legal terminal states of the EFI Driver Health Protocol is reached. This may require the processing of HII Messages, HII Form, and invocation of repair operations.

```
EFI_STATUS                          Status;
EFI_DRIVER_HEALTH_PROTOCOL          *DriverHealth;
EFI_HANDLE                          ControllerHandle;
EFI_HANDLE                          ChildHandle;
EFI_DRIVER_HEALTH_HEALTH_STATUS     HealthStatus;
EFI_DRIVER_HEALTH_HII_MESSAGE       *MessageList;
EFI_HII_HANDLE                      FormHiiHandle;

do {
     HealthStatus = EfiDriverHealthStatusHealthy;
     Status = DriverHealth->GetHealthStatus (
                  DriverHealth,
                  ControllerHandle,
                  ChildHandle,
                    &HealthStatus,
                    &MessageList,
                    &FormHiiHandle
                    );
     ProcessMessages (MessageList);
     if (HealthStatus == EfiDriverHealthStatusRepairRequired) {
      Status = DriverHealth->Repair (
                  DriverHealth,
                  ControllerHandle,
                  ChildHandle,
                  RepairNotify
                  );
   }
   if (HealthStatus == EfiDriverHealthStatusConfigurationRequired) {
    ProcessForm (FormHiiHandle
   }
  } while (HealthStatus == EfiDriverHealthStatusConfigurationRequired ||
      HealthStatus == EfiDriverHealthStatusRepairRequired);
  //
  // Check for RebootRequired or ReconnectRequired
  //
```

11.10.4.3 Repair Notification Function

The following is an example repair notification function.

```
VOID
RepairNotify (
  UINTN                   Value,
  UINTN                   Limit
  )
{
  UINTN                   Percent;

if (Limit == 0) {
  Print (L"Repair Progress Undefined\n\r");
} else {
  Percent = Value * 100 / Limit;
  Print (L"Repair Progress = %3d%%", Percent);
 }
}
```

11.10.4.4 Process Message List

The following algorithm processes a set of messages returned by the *GetHealthStatus()* service of the EFI Driver Health Protocol.

```
EFI_STATUS                         Status;
EFI_DRIVER_HEALTH_HII_MESSAGE      *MessageList;
UINTN                              MessageIndex;
EFI_HII_STRING_PROTOCOL            *HiiString;
EFI_STRING MessageString [200];

for (MessageIndex = 0;
   MessageList[MessageIndex].HiiHandle != 0;
   MessageIndex++) {
 MessageLength = sizeof (MessageString);
 Status = HiiString->GetString (
            HiiString,
            NULL,
            MessageList[MessageIndex].HiiHandle,
            MessageList[MessageIndex].StringId,
            MessageString
            &MessageLength,
            NULL
            );
 if (!EFI_ERROR (Status)) {
  // Log or Print or Display MessageString
 }
}
```

11.10.4.5 Process HII Form

The following algorithm processes an HII Form returned by the *GetHealthStatus()* service of the EFI Driver Health Protocol.

```
EFI_STATUS                          Status;
EFI_FORM_BROWSER2_PROTOCOL          *FormBrowser;
EFI_HII_HANDLE                      FormHiiHandle;

Status = FormBrowser->SendForm (
            FormBrowser,
            &FormHiiHandle,
            1,
            &gEfiHiiDriverHealthFormsetGuid,

            ,
            0,
            NULL,
            NULL
            );
```

11.10.5 UEFI Driver Algorithms

A UEFI Driver that supports the EFI Driver Health Protocol will typically make the following changes:

11.10.5.1 Driver Entry Point Updates

Install Driver Health Protocol on the driver image handle.

Register HII String/IFR packs with the HII Database.

- HII String/IFR packs can also be carried in a PE/COFF image extension eliminating the need for the driver to perform the registration
- The HII String and HII Forms may be produced dynamically when the GetHealthStatus() service is called.

11.10.5.2 Add global variable

Add global variable to track combined health status of all controllers managed by the driver. The variable is **TRUE** if all the controllers managed by the driver are healthy. The variable is **FALSE** if one or more controllers managed by the drover are not healthy.

11.10.5.3 Update private context structure

Update private context structure to track health status of each controller managed by the driver. This may also include the current set of HII Strings and HII Forms associated with the controllers that are not healthy.

11.10.5.4 Implement GetHealthStatus() service

Implement GetHealthStatus() service of the EFI Driver Health Protocol

- Make sure only legal state transitions are implemented
- Evaluate configuration data and repair status
- Return HII Strings for message(s) associated with thecurren t state
- If configuration required, return HII Form to be processed

11.10.5.5 Implement Repair() service

Implement Repair() service of the EFI Driver Health Protocol

- Calling Repair Notification callback is optional, but recommended.
- Update health status in private context structure before returning
- Make sure only legal state transitions are implemented

11.11 EFI Adapter Information Protocol

This section provides a detailed description of the *EFI_ADAPTER_INFORMATION_PROTOCOL* . The EFI Adapter Information Protocol is used to dynamically and quickly discover or set device information for an adapter. The discovery of information and state of an adapter should be quick and only return dynamic information. The information should never be cached or stale. The setting information for the adapter should also be fast and simple. The only information that should be set is operating state information, like setting a speed. This protocol is meant to be light weight and non-blocking.

11.11.1 EFI_ADAPTER_INFORMATION_PROTOCOL

Summary

Since this protocol will return and set information for the adapter, the adapter device driver must publish the *EFI_ADAPTER_INFORMATION_PROTOCOL*.

There are many kinds of adapters. The set and get adapter information functions should be used to determine the current state of the adapter, or to set a state for an adapter, like device speed.

GUID

```
#define EFI_ADAPTER_INFORMATION_PROTOCOL_GUID \
 { 0xE5DD1403, 0xD622, 0xC24E, \
 { 0x84, 0x88, 0xC7, 0x1B, 0x17, 0xF5, 0xE8, 0x02 } }
```

Protocol Interface Structure

```
typedef struct _EFI_ADAPTER_INFORMATION_PROTOCOL {
 EFI_ADAPTER_INFO_GET_INFO                   GetInformation;
 EFI_ADAPTER_INFO_SET_INFO                   SetInformation;
 EFI_ADAPTER_INFO_GET_SUPPORTED_TYPES        GetSupportedTypes;
} EFI_ADAPTER_INFORMATION_PROTOCOL;
```

Parameters

GetInformation

Gets device state information from adapter. See *GetInformation()* for more function description.

SetInformation

Sets device information for adapter. See *SetInformation()* for more function description.

GetSupportedTypes

Gets a list of supported information types for this instance of the protocol.

Description

The *EFI_ADAPTER_INFORMATION_PROTOCOL* is used to get or set the state for an adapter.

11.11.2 EFI_ADAPTER_INFORMATION_PROTOCOL.EFI_ADAPTER_GET_INFO()

Summary

Returns the current state information for the adapter.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_ADAPTER_INFO_GET_INFO) (
   IN   EFI_ADAPTER_INFORMATION_PROTOCOL          *This,
   IN   EFI_GUID                                  *InformationType,
   OUT   VOID                                     **InformationBlock,
   OUT   UINTN                                    *InformationBlockSize
   );
```

Parameters

This

A pointer to the *EFI_ADAPTER_INFORMATION_PROTOCOL* instance.

InformationType

A pointer to an *EFI_GUID* that defines the contents of *InformationBlock* . The caller must use the *InformationType* to specify the information it needs to retrieve from this service and to determine how to parse the *InformationBlock* . The driver should not attempt to free *InformationType* .

InformationBlock

This service returns a pointer to the buffer with the *InformationBlock* structure which contains details about the data specific to *InformationType* . This structure is defined based on the type of data returned, and will be different for different data types. This service and caller decode this structure and its contents based on *InformationType* . This buffer is allocated by this service, and it is the responsibility of the caller to free it after using it. Ignored if InformationBlockSize is 0.

InformationBlockSize

The driver returns the size of the *InformationBlock* in bytes.

Description

The *GetInformation()* function returns information of type *InformationType* from the adapter. If an adapter does not support the requested informational type, then *EFI_UNSUPPORTED* is returned. If an adapter does not contain Information for the requested InformationType, it fills InformationBlockSize with 0 and returns EFI_NOT_FOUND.

Status Codes Returned

EFI_SUCCESS	The *InformationType* information was retrieved.
EFI_UNSUPPORTED	The *InformationType* is not known.
EFI_NOT_FOUND	Information is not available for the requested information type.
EFI_DEVICE_ERROR	The device reported an error.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources
EFI_INVALID_PARAMETER	*This* is *NULL*
EFI_INVALID_PARAMETER	*InformationBlock* is *NULL*
EFI_INVALID_PARAMETER	*InformationBlockSize* is *NULL*

11.11.3 EFI_ADAPTER_INFORMATION_PROTOCOL.EFI_ADAPTER_INFO_SET_INFO()

Summary

Sets state information for an adapter.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_ADAPTER_INFO_SET_INFO) (
   IN   EFI_ADAPTER_INFORMATION_PROTOCOL       *This,
   IN   EFI_GUID                               *InformationType,
   IN   VOID                                   *InformationBlock,
   IN   UINTN                                  InformationBlockSize
   );
```

Parameters

This

A pointer to the *EFI_ADAPTER_INFORMATION_PROTOCOL* instance.

InformationType

A pointer to an *EFI_GUID* that defines the contents of *InformationBlock* . The caller must use the *InformationType* to specify the information it wants the service.

InformationBlock

A pointer to the *InformationBlock* structure which contains details about the data specific to *InformationType* . This structure is defined based on the type of data sent, and will be different for different data types. The driver and caller decode this structure and its contents based on *InformationType* . This buffer is allocated by the caller. It is the responsibility of the caller to free it after the caller has set the requested parameters.

InformationBlockSize

The size of the *InformationBlock* in bytes.

Description

The *SetInformation()* function sends information of type *InformationType* for an adapter. If an adapter does not support the requested informational type, then *EFI_UNSUPPORTED* is returned.

Related Definitions

Status Codes Returned

EFI_SUCCESS	The information was received and interpreted successfully.
EFI_UNSUPPORTED	The *InformationType* is not known.
EFI_DEVICE_ERROR	The device reported an error.

continues on next page

Table 11.18 – continued from previous page

EFI_INVALID_PARAMETER	*This* is *NULL*
EFI_INVALID_PARAMETER	*InformationBlock* is *NULL*
EFI_WRITE_PROTECTED	The *InformationType* cannot be modified using *EFI_ADAPTER_INFO_SET_INFO()*

11.11.4 EFI_ADAPTER_INFORMATION_PROTOCOL .EFI_ADAPTER_INFO_GET_SUPPORTED_T

Summary

Get a list of supported information types for this instance of the protocol.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_ADAPTER_INFO_GET_SUPPORTED_TYPES) (
   IN   EFI_ADAPTER_INFORMATION_PROTOCOL         *This,
   OUT  EFI_GUID                                 **InfoTypesBuffer,
   OUT  UINTN                                    *InfoTypesBufferCount
    ) ;
```

Parameters

This
A pointer to the *EFI_ADAPTER_INFORMATION_PROTOCOL* instance.

InfoTypesBuffer
A pointer to the array of InformationType GUIDs that are supported by This. This buffer is allocated by this service, and it is the responsibility of the caller to free it after using it

InfoTypesBufferCount
A pointer to the number of GUIDs present in *InfoTypesBuffer* .

Description

The *GetSupportedTypes()* function returns a list of *InformationType* GUIDs that are supported on an adapter with this instance of *EFI_ADAPTER_INFORMATION_PROTOCOL* . The list is returned in *InfoTypesBuffer* , and the number of GUID pointers in *InfoTypesBuffer* is returned in *InfoTypesBufferCount*.

Status Codes Returned

EFI_SUCCESS	The list of information type GUIDs that are supported on this adapter was returned in *InfoTypesBuffer* . The number of information type GUIDs was returned in *InfoTypesBufferCount* .
EFI_INVALID_PARAMETER	*This* is *NULL*
EFI_INVALID_PARAMETER	*InfoTypesBuffer* is *NULL*
EFI_INVALID_PARAMETER	*InfoTypesBufferCount* is *NULL*
EFI_OUT_OF_RESOURCES	There is not enough pool memory to store the results

11.12 EFI Adapter Information Protocol Information Types

Note: *In addition to the information block types defined in this section, driver writers may define additional information type blocks for their own use provided all such blocks are each identified by a unique GUID created by the definer.*

Clients of the protocol should ignore any unrecognized block types returned by *GetSupportedTypes()*.

11.12.1 Network Media State

For network adapters, the *EFI_ADAPTER_INFORMATION_PROTOCOL* must be installed on the same handle as the UNDI protocol. If SNP or MNP protocol, instead of the UNDI protocol, is installed on adapter handle, then the *EFI_ADAPTER_INFORMATION_PROTOCOL* must be installed on the same handle as the SNP or MNP protocol.

InformationType

```
#define EFI_ADAPTER_INFO_MEDIA_STATE_GUID \
 {0xD7C74207, 0xA831, 0x4A26 \
 {0xB1,0xF5,0xD1,0x93,0x06,0x5C,0xE8,0xB6}}
```

Corresponding *InformationBlock*:

```
typedef struct {
   EFI_STATUS                    MediaState;
} EFI_ADAPTER_INFO_MEDIA_STATE;
```

MediaState

Returns the current media state status. *MediaState* can have any of the following values:

EFI_SUCCESS : There is media attached to the network adapter.

EFI_NOT_READY : This detects a bounced state. There was media attached to the network adapter, but it was removed and is trying to attach to the network adapter again. If re-attached, the status will be updated to *EFI_SUCCESS* later.

EFI_NO_MEDIA : There is not any media attached to the network adapter.

11.12.2 Network Boot

For iSCSI and FCoE HBA adapters, the *EFI_ADAPTER_INFORMATION_PROTOCOL* must be installed on the same handle as the *EFI_EXT_SCSI_PASS_THRU_PROTOCOL* . When the *EFI_EXT_SCSI_PASS_THRU_PROTOCOL* cannot be installed because the adapter was not adequately configured, or if the relevant SCSI bus handles cannot be produced, this information must be installed on the controller handle that has been passed to the adapter Pass Thru Driver's *EFI_DRIVER_BINDING_PROTOCOL.Start() function* . This will typically be a handle with the *EFI_PCI_IO_PROTOCOL* and *EFI_DEVICE_PATH_PROTOCOL* . If the handle with the *EFI_EXT_SCSI_PASS_THRU_PROTOCOL* is produced at a later time, the information on the controller handle must be uninstalled so as to avoid duplicate information.

InformationType

```
#define EFI_ADAPTER_INFO_NETWORK_BOOT_GUID \
 {0x1FBD2960, 0x4130, 0x41E5,\
 {0x94,0xAC,0xD2, 0xCF, 0x03, 0x7F, 0xB3, 0x7C}}
```

Corresponding *InformationBlock*

```
typedef struct {
 BOOLEAN                  iSsciIpv4BootCapablity;
 BOOLEAN                  iScsiIpv6BootCapablity;
 BOOLEAN                  FCoeBootCapablity;
 BOOLEAN                  OffloadCapability;
 BOOLEAN                  iScsiMpioCapability
 BOOLEAN                  iScsiIpv4Boot;
 BOOLEAN                  iScsiIpv6Boot;
 BOOLEAN                  FCoeBoot;
} EFI_ADAPTER_INFO_NETWORK_BOOT;
```

iScsiIpv4BootCapablity
: **TRUE** if the adapter supports booting from iSCSI IPv4 targets.

iScsiIpv6BootCapablity
: **TRUE** if the adapter supports booting from iSCSI IPv6 targets.

FCoeBootCapablity
: **TRUE** if the adapter supports booting from FCoE targets.

OffloadCapability
: **TRUE** if the adapter supports an offload engine (such as TCP Offload Engine (TOE) for its iSCSI or FCoE boot operations.

iScsiMpioCapability
: **TRUE** if the adapter supports multipath I/O (MPIO) for its iSCSI boot operations.

iScsiIpv4Boot
: **TRUE** if the adapter is currently configured to boot from iSCSI IPv4 targets.

iScsiIpv6Boot
: **TRUE** if the adapter is currently configured to boot from iSCSI IPv6 targets.

FCoeBoot
: **TRUE** if the adapter is currently configured to boot from FCoE targets.

Note: *The adapter should set the* iScsiIpv4BootCapablity, iScsiIpv6BootCapablity, or FCoeBootCapablity *fields to* **TRUE** *if it supports that boot capability, even if that capability is currently disabled or not configured.*

11.12.3 SAN MAC Address

Summary

This information block for the *EFI_ADAPTER_INFORMATION_PROTOCOL* supports ascertaining the SAN MAC address for an FCOE-aware network interface controller. This address is the Fabric-Provided MAC Address (FPMA) that gets assigned to the adapter port after the fabric login.

Note: *An instance of the* EFI_ADAPTER_INFORMATION_PROTOCOL *supporting this GUID must be installed on the same handle as the* EFI_EXT_SCSI_PASS_THRU_PROTOCOL *when it is produced. However, this address is available to the adapter only when the fabric login has occurred, so in cases where the login cannot happen, where the* *adapter was not adequately configured, or if the relevant SCSI bus handles cannot be produced, this information type may not be produced.*

SAN MAC address information *InformationType*

```
#define EFI_ADAPTER_INFO_SAN_MAC_ADDRESS_GUID \
 {0x114da5ef, 0x2cf1, 0x4e12,\
  {0x9b, 0xbb, 0xc4, 0x70, 0xb5, 0x52, 0x05, 0xd9}}
```

Corresponding *InformationBlock*

```
typedef struct {
 EFI_MAC_ADDRESS                     SanMacAddress;
} EFI_ADAPTER_INFO_SAN_MAC_ADDRESS;
```

SanMacAddress
Returns the SAN MAC address for the adapter.

11.12.4 IPV6 Support from UNDI

For network adapters, the *EFI_ADAPTER_INFORMATION_PROTOCOL* must be installed on the same handle as the UNDI protocol.

- *Ipv6Support* re *turns capability of UNDI to support IPV6 traffic.*
- *Ipv6Support can have any of the following values:* :

TRUE : The UNDI supports IPV6.
FALSE : This UNDI does not support IPV6 traffic.

InformationType

```
#define EFI_ADAPTER_INFO_UNDI_IPV6_SUPPORT_GUID \
{ 0x4bd56be3, 0x4975, 0x4d8a, \
{0xa0, 0xad, 0xc4, 0x91, 0x20, 0x4b, 0x5d, 0x4d}}
```

Corresponding *InformationBlock*

```
typedef struct {
  BOOLEAN  Ipv6Support;
} EFI_ADAPTER_INFO_UNDI_IPV6_SUPPORT;
```

11.12.5 Network Media Type

For network adapters, the EFI_ADAPTER_INFORMATION_PROTOCOL must be installed on the same handle as the UNDI protocol. If SNP or MNP protocol, instead of the UNDI protocol, is installed on adapter handle, then the EFI_ADAPTER_INFORMATION_PROTOCOL must be installed on the same handle as the SNP or MNP protocol.

Information Type

```
#define EFI_ADAPTER_INFO_MEDIA_TYPE_GUID \
{ 0x8484472f, 0x71ec, 0x411a, \
{ 0xb3, 0x9c, 0x62, 0xcd, 0x94, 0xd9, 0x91, 0x6e }}
```

Corresponding *InformationBlock:*

```
typedef struct {
UINT8 MediaType;
} EFI_ADAPTER_INFO_MEDIA_TYPE;
```

MediaType indicates the current media type, and can have any of the following values:

1: Ethernet Network Adapter

2: Ethernet Wireless Network Adapter

3~255: Reserved

11.12.6 Coherent Device Attribute Table (CDAT) Type

This section defines Adapter Information Protocol type for Coherent Device Attribute Table (CDAT). Compute Express Link (CXL) and other CPU-to-Memory interconnects enable coherent memory devices or coherent accelerator devices to be attached to the CPU. Unlike memory DIMMs, the system software or firmware may not have apriori knowledge of the attributes of memory located on these devices and would benefit from the device directly exposing the NUMA attributes such as latency and bandwidth characteristics. The necessary data structures are defined in the Coherent Device Attribute Table (CDAT) structures. For more information, refer to “Links to UEFI-Related Documents” (* http://uefi.org/uefi *) under the heading “Coherent Device Attribute Table (CDAT) Specification”.*

Note: *For CXL devices that support coherent memory, the* EFI_ADAPTER_INFORMATION_PROTOCOL *instance supporting this type may be installed by the EFI driver associated with this device on the device controller handle. This may happen during the driver initialization in the EFI_IMAGE_ENTRY_POINT of the driver, allowing for the CDAT structures to be published without relying on the Driver Model platform connect policy*.

Information Type

```
#define EFI_ADAPTER_INFO_CDAT_TYPE_GUID \\
{0x77af24d1, 0xb6f0, 0x42b9, \\
{0x83, 0xf5, 0x8f, 0xe6, 0xe8, 0x3e, 0xb6, 0xf0}}
```

Corresponding *InformationBlock:*

```
typedef struct {
   UINTN CdatSize;
   UINT8 Cdat[];
} EFI_ADAPTER_INFO_CDAT_TYPE_TYPE;
```

CdatSize of the Cdat structure, in bytes.

CdatCoherent Device Attribute Table (CDAT) structures.

CHAPTER

TWELVE

PROTOCOLS — CONSOLE SUPPORT

This section explores console support protocols, including SimpleText Input, Simple Text Output, Simple Pointer, Serial IO, andGraphics Output protocols.

12.1 Console I/O Protocol

This section defines the Console I/O protocol. This protocol isused to handle input and output of text-based information intended for the system user during the operation of code in the boot services environment. Also included here are the definitions of three console devices: one for input and one each for normal output and errors.

These interfaces are specified by function call definitions to allow maximum flexibility in implementation. For example, there is no requirement for compliant systems to have a keyboard or screen directly connected to the system. Implementations may choose to direct information passed using these interfaces in arbitrary ways provided that the semantics of the functions are preserved (in other words, provided that the information is passed to and from the system user).

12.1.1 Overview

The UEFI console is built out of the *EFI_SIMPLE_TEXT_INPUT_PROTOCOL* and the *EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL* . These two protocols implement a basic text-based console that allows platform firmware, applications written to this specification, and UEFI OS loaders to present information to and receive input from a system administrator. The UEFI console supported 16-bit Unicode character codes, a simple set of input control characters (Scan Codes), and a set of output-oriented programmatic interfaces that give functionality equivalent to an intelligent terminal. The console does not support pointing devices on input or bitmaps on output.

This specification requires that the *EFI_SIMPLE_TEXT_INPUT_PROTOCOL* support the same languages as the corresponding EFI_ *SIMPLE_TEXT_OUTPUT_PROTOCOL* . The *EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL* is recommended to support at least the printable Basic Latin Unicode character set to enable standard terminal emulation software to be used with an EFI console. The Basic Latin Unicode character set implements a superset of ASCII that has been extended to 16-bit characters. Any number of other Unicode character sets may be optionally supported.

12.1.2 ConsoleIn Definition

The *EFI_SIMPLE_TEXT_INPUT_PROTOCOL* defines an input stream that contains Unicode characters and required EFI scan codes. Only the control characters defined in *Supported Unicode Control Characters* have meaning in the Unicode input or output streams. The control characters are defined to be characters U+0000 through U+001F. The input stream does not support any software flow control.

Table 12.1: Supported Unicode Control Characters

Mnemonic	Unicode	Description
Null	U+0000	Null character ignored when received.
BS	U+0008	Backspace. Moves cursor left one column. If the cursor is at the left margin, no action is taken.
TAB	U+0x0009	Tab.
LF	U+000A	Linefeed. Moves cursor to the next line.
CR	U+000D	Carriage Return. Moves cursor to left margin of the current line.

The input stream supports Scan Codes in addition to Unicode characters. If the Scan Code is set to 0x00 then the Unicode character is valid and should be used. If the Scan Code is set to a non-0x00 value it represents a special key as defined by the Table *EFI Scan Codes for EFI_SIMPLE_TEXT_INPUT_PROTOCOL*.

12.2 Simple Text Input Ex Protocol

The Simple Text Input Ex protocol defines an extension to the Simple Text Input protocol which enables various new capabilities describes in this section.

12.2.1 EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL

Summary

This protocol is used to obtain input from the *ConsoleIn* device. The EFI specification requires that the *EFI_SIMPLE_TEXT_INPUT_PROTOCOL* supports the same languages as the corresponding *EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL*.

GUID

```
#define EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL_GUID \
 {0xdd9e7534, 0x7762, 0x4698, \
  {0x8c, 0x14, 0xf5, 0x85, 0x17, 0xa6, 0x25, 0xaa}}
```

Protocol Interface Structure

```
typedef struct _EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL {
 EFI_INPUT_RESET_EX                          Reset;
 EFI_INPUT_READ_KEY_EX                       ReadKeyStrokeEx;
 EFI_EVENT                                   WaitForKeyEx;
 EFI_SET_STATE                               SetState;
 EFI_REGISTER_KEYSTROKE_NOTIFY               RegisterKeyNotify;
 EFI_UNREGISTER_KEYSTROKE_NOTIFY             UnregisterKeyNotify;
} EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL;
```

Parameters

Reset
Reset the *ConsoleIn* device. See *Reset()*.

ReadKeyStrokeEx
Returns the next input character. See *ReadKeyStrokeEx()*.

WaitForKeyEx
Event to use with *WaitForEvent()* to wait for a key to be available. An Event will only be triggered if *KeyData.Key* has information contained within it.

SetState
Set the *EFI_KEY_TOGGLE_STATE* state settings for the input device.

RegisterKeyNotify
Register a notification function to be called when a given key sequence is hit.

UnregisterKeyNotify
Removes a specific notification function.

Description

The *EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL* is used on the *ConsoleIn* device. It is an extension to the Simple Text Input protocol which allows a variety of extended shift state information to be returned.

12.2.2 EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL.Reset()

Summary

Resets the input device hardware.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_INPUT_RESET_EX) (
 IN EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL        *This,
 IN BOOLEAN                                  ExtendedVerification
 );
```

Parameters

This
A pointer to the *EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL* instance. Type *EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL* is defined in this section.

ExtendedVerification
Indicates that the driver may perform a more exhaustive verification operation of the device during reset.

Description

The *Reset()* function resets the input device hardware.

The implementation of Reset is required to clear the contents of any input queues resident in memory used for buffering keystroke data and put the input stream in a known empty state.

As part of initialization process, the firmware/device will make a quick but reasonable attempt to verify that the device is functioning. If the *ExtendedVerification* flag is *TRUE* the firmware may take an extended amount of time to verify the device is operating on reset. Otherwise the reset operation is to occur as quickly as possible.

The hardware verification process is not defined by this specification and is left up to the platform firmware or driver to implement.

Status Codes Returned

EFI_SUCCESS	The device was reset.
EFI_DEVICE_ERROR	The device is not functioning correctly and could not be reset.

12.2.3 EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL.ReadKeyStrokeEx()

Summary

Reads the next keystroke from the input device.

```
Prototype
typedef
EFI_STATUS
(EFIAPI *EFI_INPUT_READ_KEY_EX) (
 IN EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL     *This,
 OUT EFI_KEY_DATA                         *KeyData
 );
```

Parameters

This

A pointer to the *EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL* instance. Type *EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL* is defined in this section.

KeyData

A pointer to a buffer that is filled in with the keystroke state data for the key that was pressed. Type *EFI_KEY_DATA* is defined in "Related Definitions" below.

Related Definitions

```
//*******************************************
// EFI_KEY_DATA
//*******************************************
typedef struct {
 EFI_INPUT_KEY           Key;
 EFI_KEY_STATE           KeyState;
} EFI_KEY_DATA
```

Key

The EFI scan code and Unicode value returned from the input device.

KeyState

The current state of various toggled attributes as well as input modifier values.

```
//*****************************************************
// EFI_KEY_STATE
//*****************************************************
//
// Any Shift or Toggle State that is valid should have
// high order bit set.
//
typedef struct EFI_KEY_STATE {
 UINT32                       KeyShiftState;
```

(continues on next page)

(continued from previous page)

```
 EFI_KEY_TOGGLE_STATE         KeyToggleState;
} EFI_KEY_STATE;
```

KeyShiftState
Reflects the currently pressed shift modifiers for the input device. The returned value is valid only if the high order bit has been set.

KeyToggleState
Reflects the current internal state of various toggled attributes. The returned value is valid only if the high order bit has been set.

```
#define EFI_SHIFT_STATE_VALID          0x80000000
#define EFI_RIGHT_SHIFT_PRESSED        0x00000001
#define EFI_LEFT_SHIFT_PRESSED         0x00000002
#define EFI_RIGHT_CONTROL_PRESSED      0x00000004
#define EFI_LEFT_CONTROL_PRESSED       0x00000008
#define EFI_RIGHT_ALT_PRESSED          0x00000010
#define EFI_LEFT_ALT_PRESSED           0x00000020
#define EFI_RIGHT_LOGO_PRESSED         0x00000040
#define EFI_LEFT_LOGO_PRESSED          0x00000080
#define EFI_MENU_KEY_PRESSED           0x00000100
#define EFI_SYS_REQ_PRESSED            0x00000200

//*******************************************************
// EFI_KEY_TOGGLE_STATE
//*******************************************************
typedef UINT8 EFI_KEY_TOGGLE_STATE;

#define EFI_TOGGLE_STATE_VALID 0x80
#define EFI_KEY_STATE_EXPOSED 0x40
#define EFI_SCROLL_LOCK_ACTIVE 0x01
#define EFI_NUM_LOCK_ACTIVE 0x02
#define EFI_CAPS_LOCK_ACTIVE 0x04
```

Description

The *ReadKeyStrokeEx()* function reads the next keystroke from the input device. If there is no pending keystroke the function returns *EFI_NOT_READY* . If there is a pending keystroke, then *KeyData.Key.ScanCode* is the EFI scan code defined in *EFI Scan Codes for EFI_SIMPLE_TEXT_INPUT_PROTOCOL* . The *KeyData.Key.UnicodeChar* is the actual printable character or is zero if the key does not represent a printable character (control key, function key, etc.). The *KeyData.KeyState* is the modifier shift state for the character reflected in *KeyData.Key.UnicodeChar* or *KeyData.Key.ScanCode*. This function mirrors the behavior of *ReadKeyStroke(* in the Simple Input Protocol in that a keystroke will only be returned when *KeyData.Key* has data within it.

When interpreting the data from this function, it should be noted that if a class of printable characters that are normally adjusted by shift modifiers (e.g. Shift Key + “f” key) would be presented solely as a *KeyData.Key.UnicodeChar* without the associated shift state. So in the previous example of a Shift Key + “f” key being pressed, the only pertinent data returned would be *KeyData.Key.UnicodeChar* with the value of “F”. This of course would not typically be the case for non-printable characters such as the pressing of the Right Shift Key + F10 key since the corresponding returned data would be reflected both in the *KeyData.KeyState.KeyShiftState* and *KeyData.Key.ScanCode* values.

UEFI drivers which implement the *EFI_SIMPLE_TEXT_INPUT_EX* protocol are required to return *KeyData.Key* and *KeyData.KeyState* values. These drivers must always return the most current state of *KeyData.KeyState.KeyShiftState* and *KeyData.KeyState.KeyToggleState* . It should also be noted that certain input devices may not be able to produce shift or toggle state information, and in those cases the high order bit in the respective Toggle and Shift state fields should not be active.

If the *EFI_KEY_STATE_EXPOSED* bit is turned on, then this instance of the *EFI_SIMPLE_INPUT_EX_PROTOCOL* supports the ability to return partial keystrokes. With *EFI_KEY_STATE_EXPOSED* bit enabled, the *ReadKeyStrokeEx* function will allow the return of incomplete keystrokes such as the holding down of certain keys which are expressed as a part of *KeyState* when there is no *Key* data.

Status Codes Returned

EFI_SUCCESS	The keystroke information was returned.
EFI_NOT_READY	There was no keystroke data available.. Current KeyData.KeyState values are exposed.
EFI_DEVICE_ERROR	The keystroke information was not returned due to hardware errors.
EFI_UNSUPPORTED	The device does not support the ability to read keystroke data.

12.2.4 EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL.SetState()

Summary

Set certain state for the input device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI \*EFI_SET_STATE) (
 IN EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL         *This,
 IN EFI_KEY_TOGGLE_STATE                      *KeyToggleState
 );
```

Parameters

This

A pointer to the *EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL* instance. Type *EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL* is defined in this section.

KeyToggleState

Pointer to the *EFI_KEY_TOGGLE_STATE* to set the state for the input device. Type *EFI_KEY_TOGGLE_STATE* is defined in "Related Definitions" for *EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL.ReadKeyStrokeEx()* , above.

The SetState() function allows the input device hardware to have state settings adjusted. By calling the SetState() function with the *EFI_KEY_STATE_EXPOSED* bit active in the *KeyToggleState* parameter, this will enable the *ReadKeyStrokeEx* function to return incomplete keystrokes such as the holding down of certain keys which are expressed as a part of KeyState when there is no Key data.

Status Codes Returned

EFI_SUCCESS	The device state was set appropriately.
EFI_DEVICE_ERROR	The device is not functioning correctly and could not have the setting adjusted.
EFI_UNSUPPORTED	The device does not support the ability to have its state set or the requested state change was not supported.

12.2.5 EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL.RegisterKeyNotify()

Summary

Register a notification function for a particular keystroke for the input device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_REGISTER_KEYSTROKE_NOTIFY) (
 IN EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL            *This,
 IN EFI_KEY_DATA                                 *KeyData,
 IN EFI_KEY_NOTIFY_FUNCTION                      KeyNotificationFunction,
 OUT VOID                                        **NotifyHandle
 );
```

Parameters

This

A pointer to the *EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL* instance. Type *EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL* is defined in this section.

KeyData

A pointer to a buffer that is filled in with the keystroke information for the key that was pressed. If KeyData.Key, KeyData.KeyState.KeyToggleState and KeyData.KeyState.KeyShiftState are 0, then any incomplete keystroke will trigger a notification of the KeyNotificationFunction.

KeyNotificationFunction

Points to the function to be called when the key sequence is typed specified by *KeyData* . This notification function should be called at <= *TPL_CALLBACK*. See *EFI_KEY_NOTIFY_FUNCTION* below.

NotifyHandle

Points to the unique handle assigned to the registered notification.

Description

The *RegisterKeystrokeNotify()* function registers a function which will be called when a specified keystroke will occur. The keystroke being specified can be for any combination of *KeyData.Key* or *KeyData.KeyState* information.

Related Definitions

```
//*******************************************************
// EFI_KEY_NOTIFY
//*******************************************************
typedef
EFI_STATUS
(EFIAPI \*EFI_KEY_NOTIFY_FUNCTION) (
 IN EFI_KEY_DATA                        *KeyData
 );
```

Status Codes Returned

EFI_SUCCESS	Key notify was registered successfully.
EFI_OUT_OF_RESOURCES	Unable to allocate necessary data structures.

12.2.6 EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL.UnregisterKeyNotify()

Summary

Remove the notification that was previously registered.

Prototype

```
 typedef
 EFI_STATUS
 (EFIAPI *EFI_UNREGISTER_KEYSTROKE_NOTIFY) (
  IN EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL *This,
  IN VOID                              *NotificationHandle
  );

**Parameters**
```

This

A pointer to the *EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL* instance. Type *EFI_SIMPLE_TEXT_INPUT_EX_PROTOCOL* is defined in this section.

NotificationHandle

The handle of the notification function being unregistered.

Description

The *UnregisterKeystrokeNotify()* function removes the notification which was previously registered.

Status Codes Returned

EFI_SUCCESS	Key notify was unregistered successfully.
EFI_INVALID_PARAMETER	The NotificationHandle is invalid.

12.3 Simple Text Input Protocol

The Simple Text Input protocol defines the minimum input required to support the ConsoleIn device.

12.3.1 EFI_SIMPLE_TEXT_INPUT_PROTOCOL

Summary

This protocol is used to obtain input from the ConsoleIn device. The EFI specification requires that the *EFI_SIMPLE_TEXT_INPUT_PROTOCOL* supports the same languages as the corresponding *EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL*.

GUID

```
#define EFI_SIMPLE_TEXT_INPUT_PROTOCOL_GUID \
 {0x387477c1,0x69c7,0x11d2,\
  {0x8e,0x39,0x00,0xa0,0xc9,0x69,0x72,0x3b}}
```

Protocol Interface Structure

```
typedef struct _EFI_SIMPLE_TEXT_INPUT_PROTOCOL {
 EFI_INPUT_RESET                       Reset;
 EFI_INPUT_READ_KEY                    ReadKeyStroke;
 EFI_EVENT                             WaitForKey;
} EFI_SIMPLE_TEXT_INPUT_PROTOCOL;
```

Parameters

Reset
Reset the ConsoleIn device, *EFI_SIMPLE_TEXT_INPUT_PROTOCOL.Reset()* .

ReadKeyStroke
Returns the next input character, *EFI_SIMPLE_TEXT_INPUT_PROTOCOL.ReadKeyStroke()* .

WaitForKey
Event to use with *EFI_BOOT_SERVICES.WaitForEvent()* to wait for a key to be available.

Description

The *EFI_SIMPLE_TEXT_INPUT_PROTOCOL* is used on the ConsoleIn device. It is the minimum required protocol for ConsoleIn.

12.3.2 EFI_SIMPLE_TEXT_INPUT_PROTOCOL.Reset()

Summary

Resets the input device hardware.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_INPUT_RESET) (
 IN EFI_SIMPLE_TEXT_INPUT_PROTOCOL                  *This,
 IN BOOLEAN                                         ExtendedVerification
 );
```

Parameters

This
A pointer to the *EFI_SIMPLE_TEXT_INPUT_PROTOCOL* instance. Type EFI_SIMPLE_TEXT_INPUT_PROTOCOL is defined in *EFI_SIMPLE_TEXT_INPUT_PROTOCOL*

ExtendedVerification
Indicates that the driver may perform a more exhaustive verification operation of the device during reset.

Description

The Reset() function resets the input device hardware.

The implementation of Reset is required to clear the contents of any input queues resident in memory used for buffering keystroke data and put the input stream in a known empty state.

As part of initialization process, the firmware/device will make a quick but reasonable attempt to verify that the device is functioning. If the ExtendedVerification flag is **TRUE** the firmware may take an extended amount of time to verify the device is operating on reset. Otherwise the reset operation is to occur as quickly as possible.

The hardware verification process is not defined by this specification and is left up to the platform firmware or driver to implement.

Status Codes Returned

EFI_SUCCESS	The device was reset.
EFI_DEVICE_ERROR	The device is not functioning correctly and could not be reset.

12.3.3 EFI_SIMPLE_TEXT_INPUT_PROTOCOL.ReadKeyStroke()

Summary

Reads the next keystroke from the input device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI \*EFI_INPUT_READ_KEY) (
 IN EFI_SIMPLE_TEXT_INPUT_PROTOCOL              *This,
 OUT EFI_INPUT_KEY                              *Key
 );
```

Parameters

This

A pointer to the EFI_SIMPLE_TEXT_INPUT_PROTOCOL instance. Type EFI_SIMPLE_TEXT_INPUT_PROTOCOL is defined in *EFI_SIMPLE_TEXT_INPUT_PROTOCOL*

Key

A pointer to a buffer that is filled in with the keystroke information for the key that was pressed. Type EFI_INPUT_KEY is defined in "Related Definitions" below.

```
Related Definitions
//*******************************************************
// EFI_INPUT_KEY
//*******************************************************
typedef struct {
 UINT16                           ScanCode;
 CHAR16                           UnicodeChar;
} EFI_INPUT_KEY;
```

Description

The ReadKeyStroke() function reads the next keystroke from the input device. If there is no pending keystroke the function returns EFI_NOT_READY. If there is a pending keystroke, then ScanCode is the EFI scan code defined in *EFI Scan Codes for EFI_SIMPLE_TEXT_INPUT_PROTOCOL* . The UnicodeChar is the actual printable character or is zero if the key does not represent a printable character (control key, function key, etc.).

Status Codes Returned

Table 12.8: :widths: 35 70 :class: longtable

EFI_SUCCESS	The keystroke information was returned.
EFI_NOT_READY	There was no keystroke data available.
EFI_DEVICE_ERROR	The keystroke information was not returned due to hardware errors.
EFI_UNSUPPORTED	The device does not support the ability to read keystroke data.

12.3.4 ConsoleOut or StandardError

The *EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL* must implement the same Unicode code pages as the *EFI_SIMPLE_TEXT_INPUT_PROTOCOL* . The protocol must also support the Unicode control characters defined in *Supported Unicode Control Characters* . The *EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL* supports special manipulation of the screen by programmatic methods and therefore does not support the EFI scan codes defined in *EFI Scan Codes for EFI_SIMPLE_TEXT_INPUT_PROTOCOL* .

12.4 Simple Text Output Protocol

The Simple Text Output protocol defines the minimum requirements for a text-based ConsoleOut device. The EFI specification requires that the *EFI_SIMPLE_TEXT_INPUT_PROTOCOL* support the same languages as the corresponding *EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL.*

12.4.1 EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL

Summary

This protocol is used to control text-based output devices.

GUID

```
#define EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL_GUID \
 {0x387477c2,0x69c7,0x11d2,\
  {0x8e,0x39,0x00,0xa0,0xc9,0x69,0x72,0x3b}}
```

Protocol Interface Structure

```
typedef struct _EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL {
 EFI_TEXT_RESET                          Reset;
 EFI_TEXT_STRING                         OutputString;
 EFI_TEXT_TEST_STRING                    TestString;
 EFI_TEXT_QUERY_MODE                     QueryMode;
 EFI_TEXT_SET_MODE                       SetMode;
 EFI_TEXT_SET_ATTRIBUTE                  SetAttribute;
 EFI_TEXT_CLEAR_SCREEN                   ClearScreen;
 EFI_TEXT_SET_CURSOR_POSITION            SetCursorPosition;
 EFI_TEXT_ENABLE_CURSOR                  EnableCursor;
 SIMPLE_TEXT_OUTPUT_MODE                 *Mode;
} EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL;
```

Parameters

Reset

Reset the ConsoleOut device. *EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL.Reset()*.

OutputString

Displays the string on the device at the current cursor location. See OutputString() *EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL.OutputString()* .

TestString

Tests to see if the ConsoleOut device supports this string. See TestString() *EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL.TestString()* .

QueryMode

Queries information concerning the output device's supported text mode. See QueryMode() *EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL.QueryMode()* .

SetMode

Sets the current mode of the output device. *EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL.SetMode()* .

SetAttribute

Sets the foreground and background color of the text that is output. *EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL.SetAttribute()* .

ClearScreen

Clears the screen with the currently set background color. See ClearScreen() *EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL.ClearScreen()*.

SetCursorPosition

Sets the current cursor position. See SetCursorPosition() *EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL.SetCursorPosition()* .

EnableCursor

Turns the visibility of the cursor on/off. See EnableCursor() *EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL.EnableCursor()* .

Mode

Pointer to SIMPLE_TEXT_OUTPUT_MODE data. Type SIMPLE_TEXT_OUTPUT_MODE is defined in "Related Definitions" below.

The following data values in the SIMPLE_TEXT_OUTPUT_MODE interface are read-only and are changed by using the appropriate interface functions:

MaxMode

The number of modes supported by QueryMode() and SetMode().

Mode

The text mode of the output device(s).

Attribute

The current character output attribute.

CursorColumn

The cursor's column.

CursorRow

The cursor's row.

CursorVisible

The cursor is currently visible or not.

Related Definitions

```
//*******************************************************
// SIMPLE_TEXT_OUTPUT_MODE
//*******************************************************
typedef struct {
 INT32                              MaxMode;
 // current settings
 INT32                              Mode;
 INT32                              Attribute;
 INT32                              CursorColumn;
 INT32                              CursorRow;
```

(continues on next page)

(continued from previous page)

```
 BOOLEAN                           CursorVisible;
} SIMPLE_TEXT_OUTPUT_MODE;
```

Description

The SIMPLE_TEXT_OUTPUT protocol is used to control text-based output devices. It is the minimum required protocol for any handle supplied as the ConsoleOut or StandardError device. In addition, the minimum supported text mode of such devices is at least 80 x 25 characters.

A video device that only supports graphics mode is required to emulate text mode functionality. Output strings themselves are not allowed to contain any control codes other than those defined in *Supported Unicode Control Characters* . Positional cursor placement is done only via the SetCursorPosition() *EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL.SetCursorPosition()* function. It is highly recommended that text output to the StandardError device be limited to sequential string outputs. (That is, it is not recommended to use ClearScreen() *EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL.ClearScreen()* or *SetCursorPosition()* on output messages to StandardError.)

If the output device is not in a valid text mode at the time of the *EFI_BOOT_SERVICES.HandleProtocol()* call, the device is to indicate that its CurrentMode is -1. On connecting to the output device the caller is required to verify the mode of the output device, and if it is not acceptable to set it to something it can use.

12.4.2 EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL.Reset()

Summary

Resets the text output device hardware.

Prototype

```
typedef
EFI_STATUS
(EFIAPI \*EFI_TEXT_RESET) (
 IN EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL       *This,
 IN BOOLEAN                               ExtendedVerification
 );
```

Parameters

This

A pointer to the *EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL* instance. Type EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL is defined in the "Related Definitions" of *EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL*

ExtendedVerification

Indicates that the driver may perform a more exhaustive verification operation of the device during reset.

Description

The Reset() function resets the text output device hardware. The cursor position is set to (0, 0), and the screen is cleared to the default background color for the output device.

As part of initialization process, the firmware/device will make a quick but reasonable attempt to verify that the device is functioning. If the ExtendedVerification flag is **TRUE** the firmware may take an extended amount of time to verify the device is operating on reset. Otherwise the reset operation is to occur as quickly as possible.

The hardware verification process is not defined by this specification and is left up to the platform firmware or driver to implement.

Status Codes Returned

EFI_SUCCESS	The text output device was reset.
EFI_DEVICE_ERROR	The text output device is not functioning correctly and could not be reset.

12.4.3 EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL.OutputString()

Summary

Writes a string to the output device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_TEXT_STRING) (
 IN EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL    *This,
 IN CHAR16                             *String
 );
```

Parameters

This

A pointer to the *EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL* instance. Type EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL is defined in the "Related Definitions" of *Simple Text Output Protocol* .

String

The Null-terminated string to be displayed on the output device(s). All output devices must also support the Unicode drawing character codes defined in "Related Definitions."

Related Definitions

```

Description

The OutputString() *EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL.OutputString()* function writes a string to the output device. This is the most basic output mechanism on an output device. The String is displayed at the current cursor location on the output device(s) and the cursor is advanced according to the rules listed in *EFI Cursor Location/Advance Rules* .

Table 12.10: EFI Cursor Location/Advance Rules

Mnemonic	Unicode	Description
Null	U+0000	Ignore the character, and do not move the cursor.
BS	U+0008	If the cursor is not at the left edge of the display, then move the cursor left one column.
LF	U+000A	If the cursor is at the bottom of the display, then scroll the display one row, and do not update the cursor position. Otherwise, move the cursor down one row.
CR	U+000D	Move the cursor to the beginning of the current row.
Other	U+XXXX	Print the character at the current cursor position and move the cursor right one column. If this moves the cursor past the right edge of the display, then the line should wrap to the beginning of the next line. This is equivalent to inserting a CR and an LF. Note that if the cursor is at the bottom of the display, and the line wraps, then the display will be scrolled one line.

Note: *If desired, the system's NVRAM environment variables may be used at install time to determine the configured locale of the system or the installation procedure can query the user for the proper language support. This is then used to either install the proper EFI image/loader or to configure the installed image's strings to use the proper text for the selected locale*.

Status Codes Returned

EFI_SUCCESS	The string was output to the device.
EFI_DEVICE_ERROR	The device reported an error while attempting to output the text.
EFI_UNSUPPORTED	The output device's mode is not currently in a defined text mode.
EFI_WARN_UNKNOWN_GLYPH	This warning code indicates that some of the characters in the string could not be rendered and were skipped.

12.4.4 EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL.TestString()

Summary

Verifies that all characters in a string can be output to the target device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_TEXT_TEST_STRING) (
 IN EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL       *This,
 IN CHAR16                                *String
 );
```

Parameters

This

A pointer to the *EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL* instance. Type EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL is defined in the "Related Definitions" of *Simple Text Output Protocol*.

String

The Null-terminated string to be examined for the output device(s).

Description

The TestString() function verifies that all characters in a string can be output to the target device.

This function provides a way to know if the desired character codes are supported for rendering on the output device(s). This allows the installation procedure (or EFI image) to at least select character codes that the output devices are capable of displaying. Since the output device(s) may be changed between boots, if the loader cannot adapt to such changes it is recommended that the loader call OUTPUTSTRING() *EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL.OutputString()* with the text it has and ignore any "unsupported" error codes. Devices that are capable of displaying the Unicode character codes will do so.

Status Codes Returned

EFI_SUCCESS	The device(s) are capable of rendering the output string.
EFI_UNSUPPORTED	Some of the characters in the string cannot be rendered by one or more of the output devices mapped by the EFI handle.

12.4.5 EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL.QueryMode()

Summary

Returns information for an available text mode that the output device(s) supports.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_TEXT_QUERY_MODE) (
 IN EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL          *This,
 IN UINTN                                    ModeNumber,
 OUT UINTN                                   *Columns,
 OUT UINTN                                   *Rows
 );
```

Parameters

This

A pointer to the *EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL* instance. Type EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL is defined in the "Related Definitions" of *Simple Text Output Protocol*.

ModeNumber

The mode number to return information on.

Columns, Rows

Returns the geometry of the text output device for the request ModeNumber.

Description

The QueryMode() function returns information for an available text mode that the output device(s) supports.

It is required that all output devices support at least 80x25 text mode. This mode is defined to be mode 0. If the output devices support 80x50, that is defined to be mode 1. All other text dimensions supported by the device will follow as modes 2 and above. If an output device supports modes 2 and above, but does not support 80x50, then querying for mode 1 will return *EFI_UNSUPPORTED* .

Status Codes Returned

EFI_SUCCESS	The requested mode information was returned.
EFI_DEVICE_ERROR	The device had an error and could not complete the request.
EFI_UNSUPPORTED	The mode number was not valid.

12.4.6 EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL.SetMode()

Summary

Sets the output device(s) to a specified mode.

Prototype

```
typedef
EFI_STATUS
(* EFIAPI EFI_TEXT_SET_MODE) (
 IN EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL          *This,
 IN UINTN                                    ModeNumber
 );
```

Parameters

This

A pointer to the *EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL* instance. Type EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL is defined in the "Related Definitions" of *Simple Text Output Protocol*.

ModeNumber

The text mode to set.

Description

The SetMode() function sets the output device(s) to the requested mode. On success the device is in the geometry for the requested mode, and the device has been cleared to the current background color with the cursor at (0,0).

Status Codes Returned

EFI_SUCCESS	The requested text mode was set.
EFI_DEVICE_ERROR	The device had an error and could not complete the request.
EFI_UNSUPPORTED	The mode number was not valid.

12.4.7 EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL.SetAttribute()

Summary

Sets the background and foreground colors for the OutputString(), *EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL.OutputString()* and ClearScreen() *EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL.ClearScreen()* functions.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_TEXT_SET_ATTRIBUTE) (
 IN EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL        *This,
```

(continues on next page)

(continued from previous page)

```
IN UINTN                                  Attribute
);
```

Parameters

This

A pointer to the *EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL* instance. Type EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL is defined inthe “Related Definitions” *Simple Text Output Protocol* .

Attribute

The attribute to set. Bits 0..3 are the foreground color, and bits 4..6 are the background color. All other bits are reserved. See “Related Definitions” below.

Related Definitions

```
//*******************************************************
// Attributes
//*******************************************************
#define EFI_BLACK                              0x00

#define EFI_DARKGRAY(EFI_BLACK \| EFI_BRIGHT)  0x08
#define EFI_LIGHTBLUE                          0x09
#define EFI_LIGHTGREEN                         0x0A
#define EFI_LIGHTCYAN                          0x0B
#define EFI_LIGHTRED                           0x0C
#define EFI_LIGHTMAGENTA                       0x0D
#define EFI_YELLOW                             0x0E
#define EFI_WHITE                              0x0F

#define EFI_BACKGROUND_BLACK                   0x00
#define EFI_BACKGROUND_BLUE                    0x10
#define EFI_BACKGROUND_GREEN                   0x20
#define EFI_BACKGROUND_CYAN                    0x30
#define EFI_BACKGROUND_RED                     0x40
#define EFI_BACKGROUND_MAGENTA                 0x50
#define EFI_BACKGROUND_BROWN                   0x60
#define EFI_BACKGROUND_LIGHTGRAY               0x70
//
// Macro to accept color values in their raw form to create
// a value that represents both a foreground and background
// color in a single byte.
// For Foreground, and EFI_\* value is valid from EFI_BLACK(0x00)
// to EFI_WHITE (0x0F).
// For Background, only EFI_BLACK, EFI_BLUE, EFI_GREEN,
// EFI_CYAN, EFI_RED, EFI_MAGENTA, EFI_BROWN, and EFI_LIGHTGRAY
```

(continues on next page)

(continued from previous page)

```
// are acceptable.
//
// Do not use EFI_BACKGROUND_xxx values with this macro.
//#define EFI_TEXT_ATTR(Foreground,Background) \
((Foreground) | ((Background) << 4))
```

Description

The SetAttribute() function sets the background and foreground colors for the OutputString() *EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL.OutputString()* and ClearScreen() *EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL.ClearScreen()* functions.

The color mask can be set even when the device is in an invalid text mode.

Devices supporting a different number of text colors are required to emulate the above colors to the best of the device's capabilities.

Status Codes Returned

EFI_SUCCESS	The requested attributes were set.
EFI_DEVICE_ERROR	The device had an error and could not complete the request.

12.4.8 EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL.ClearScreen()

Summary

Clears the output device(s) display to the currently selected background color.

Prototype

```
typedef
EFI_STATUS
(EFIAPI \*EFI_TEXT_CLEAR_SCREEN) (
 IN EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL             *This
 );
```

Parameters

This

A pointer to the *EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL* instance. Type EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL is defined in the "Related Definitions" of *Simple Text Output Protocol*.

Description

The ClearScreen() function clears the output device(s) display to the currently selected background color. The cursor position is set to (0, 0).

Status Codes Returned

EFI_SUCCESS	The operation completed successfully.
EFI_DEVICE_ERROR	The device had an error and could not complete the request.
EFI_UNSUPPORTED	The output device is not in a valid text mode.

12.4.9 EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL.SetCursorPosition()

Summary

Sets the current coordinates of the cursor position.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_TEXT_SET_CURSOR_POSITION) (
 IN EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL           *This,
 IN UINTN                                     Column,
 IN UINTN                                     Row
 );
```

Parameters

This

A pointer to the *EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL* instance. Type EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL is defined in the "Related Definitions" of *Simple Text Output Protocol* .

Column, Row

The position to set the cursor to. Must greater than or equal to zero and less than the number of columns and rows returned by *EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL.QueryMode()* .

Description

The SetCursorPosition() function sets the current coordinates of the cursor position. The upper left corner of the screen is defined as coordinate (0, 0).

Status Codes Returned

EFI_SUCCESS	The operation completed successfully.
EFI_DEVICE_ERROR	The device had an error and could not complete the request.
EFI_UNSUPPORTED	The output device is not in a valid text mode, or the cursor position is invalid for the current mode.

12.4.10 EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL.EnableCursor()

Summary

Makes the cursor visible or invisible.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_TEXT_ENABLE_CURSOR) (
 IN EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL           *This,
 IN BOOLEAN                                   Visible
 );
```

Parameters

This

A pointer to the *EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL* instance. Type

EFI_SIMPLE_TEXT_OUTPUT_PROTOCOL is defined in the “Related Definitions” of *Simple Text Output Protocol* .

Visible

If **TRUE**, the cursor is set to be visible. If **FALSE**, the cursor is set to be invisible.

Description

The EnableCursor() function makes the cursor visible or invisible.

Status Codes Returned

EFI_SUCCESS	The operation completed successfully.
EFI_DEVICE_ERROR	The device had an error and could not complete the request or the device does not support changing the cursor mode.
EFI_UNSUPPORTED	The output device does not support visibility control of the cursor.

12.5 Simple Pointer Protocol

This section defines the Simple Pointer Protocol and a detailed description of the EFI_SIMPLE_POINTER_PROTOCOL. The intent of this section is to specify a simple method for accessing pointer devices. This would include devices such as mice and trackballs.

The EFI_SIMPLE_POINTER_PROTOCOL allows information about a pointer device to be retrieved. This would include the status of buttons and the motion of the pointer device since the last time it was accessed. This protocol is attached the device handle of a pointer device, and can be used for input from the user in the preboot environment.

12.5.1 EFI_SIMPLE_POINTER_PROTOCOL

Summary

Provides services that allow information about a pointer device to be retrieved.

GUID

```
#define EFI_SIMPLE_POINTER_PROTOCOL_GUID \
 {0x31878c87,0xb75,0x11d5,\
  {0x9a,0x4f,0x00,0x90,0x27,0x3f,0xc1,0x4d}}
```

Protocol Interface Structure

```
typedef struct \_EFI_SIMPLE_POINTER_PROTOCOL {
 EFI_SIMPLE_POINTER_RESET                    Reset;
 EFI_SIMPLE_POINTER_GET_STATE                GetState;
 EFI_EVENT                                   WaitForInput;
 EFI_SIMPLE_INPUT_MODE                       *Mode;
} EFI_SIMPLE_POINTER_PROTOCOL;
```

Parameters

Reset

Resets the pointer device. *EFI_SIMPLE_POINTER_PROTOCOL.Reset()* function description.

GetState

Retrieves the current state of the pointer device, *EFI_SIMPLE_POINTER_PROTOCOL.GetState()* function description.

WaitForInput
Event to use with *EFI_BOOT_SERVICES.WaitForEvent()* to wait for input from the pointer device.

Mode
Pointer to *EFI_SIMPLE_POINTER_MODE* data. The type *EFI_SIMPLE_POINTER_MODE* is defined in "Related Definitions" below.

Related Definitions

```
//*******************************************************
// EFI_SIMPLE_POINTER_MODE
//*******************************************************
typedef struct {
 UINT64                    ResolutionX;
 UINT64                    ResolutionY;
 UINT64                    ResolutionZ;
 BOOLEAN                   LeftButton;
 BOOLEAN                   RightButton;
} EFI_SIMPLE_POINTER_MODE;
```

The following data values in the EFI_SIMPLE_POINTER_MODE interface are read-only and are changed by using the appropriate interface functions:

ResolutionX
The resolution of the pointer device on the x-axis in counts/mm. If 0, then the pointer device does not support an x-axis.

ResolutionY
The resolution of the pointer device on the y-axis in counts/mm. If 0, then the pointer device does not support a y-axis.

ResolutionZ
The resolution of the pointer device on the z-axis in counts/mm. If 0, then the pointer device does not support a z-axis.

LeftButton
TRUE if a left button is present on the pointer device. Otherwise **FALSE**.

RightButton
TRUE if a right button is present on the pointer device. Otherwise **FALSE**.

Description

The EFI_SIMPLE_POINTER_PROTOCOL provides a set of services for a pointer device that can use used as an input device from an application written to this specification. The services include the ability to reset the pointer device, retrieve get the state of the pointer device, and retrieve the capabilities of the pointer device.

12.5.2 EFI_SIMPLE_POINTER_PROTOCOL.Reset()

Summary

Resets the pointer device hardware.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SIMPLE_POINTER_RESET) (
```

(continues on next page)

(continued from previous page)

```
 IN EFI_SIMPLE_POINTER_PROTOCOL             *This,
 IN BOOLEAN                                 ExtendedVerification
 );
```

Parameters

This

A pointer to the EFI_SIMPLE_POINTER_PROTOCOL instance. Type EFI_SIMPLE_POINTER_PROTOCOL is defined in *Simple Pointer Protocol* .

ExtendedVerification

Indicates that the driver may perform a more exhaustive verification operation of the device during reset.

Description

This Reset() function resets the pointer device hardware. As part of initialization process, the firmware/device will make a quick but reasonable attempt to verify that the device is functioning. If the ExtendedVerification flag is **TRUE** the firmware may take an extended amount of time to verify the device is operating on reset. Otherwise the reset operation is to occur as quickly as possible. The hardware verification process is not defined by this specification and is left up to the platform firmware or driver to implement.

Status Codes Returned

EFI_SUCCESS	The device was reset.
EFI_DEVICE_ERROR	The device is not functioning correctly and could not be reset.

12.5.3 EFI_SIMPLE_POINTER_PROTOCOL.GetState()

Summary

Retrieves the current state of a pointer device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SIMPLE_POINTER_GET_STATE)
 IN EFI_SIMPLE_POINTER_PROTOCOL             *This,
 OUT EFI_SIMPLE_POINTER_STATE               *State
 );
```

Parameters

This

A pointer to the EFI_SIMPLE_POINTER_PROTOCOL instance. Type EFI_SIMPLE_POINTER_PROTOCOL is defined in is defined in the "Related Definitions" of *Simple Pointer Protocol*

State

A pointer to the state information on the pointer device. Type EFI_SIMPLE_POINTER_STATE is defined in "Related Definitions" below.

Related Definitions

```
//*******************************************************
// EFI_SIMPLE_POINTER_STATE
//*******************************************************
```

(continues on next page)

(continued from previous page)

```
typedef struct {
 INT32                  RelativeMovementX;
 INT32                  RelativeMovementY;
 INT32                  RelativeMovementZ;
 BOOLEAN                LeftButton;
 BOOLEAN                RightButton;
} EFI_SIMPLE_POINTER_STATE;
```

RelativeMovementX

The signed distance in counts that the pointer device has been moved along the x-axis. The actual distance moved is RelativeMovementX / ResolutionX millimeters. If the ResolutionX field of the EFI_SIMPLE_POINTER_MODE see *EFI_SIMPLE_POINTER_PROTOCOL* structure is 0, then this pointer device does not support an x-axis, and this field must be ignored.

RelativeMovementY

The signed distance in counts that the pointer device has been moved along the y-axis. The actual distance moved is RelativeMovementY / ResolutionY millimeters. If the ResolutionY field of the EFI_SIMPLE_POINTER_MODE see *EFI_SIMPLE_POINTER_PROTOCOL* structure is 0, then this pointer device does not support a y-axis, and this field must be ignored.

RelativeMovementZ

The signed distance in counts that the pointer device has been moved along the z-axis. The actual distance moved is RelativeMovementZ / ResolutionZ millimeters. If the ResolutionZ field of the EFI_SIMPLE_POINTER_MODE structure is 0, then this pointer device does not support a z-axis, and this field must be ignored.

LeftButton

If **TRUE**, then the left button of the pointer device is being pressed. If **FALSE**, then the left button of the pointer device is not being pressed. If the LeftButton field of the EFI_SIMPLE_POINTER_MODE see *EFI_SIMPLE_POINTER_PROTOCOL* structure is **FALSE**, then this field is not valid, and must be ignored.

RightButton

If **TRUE**, then the right button of the pointer device is being pressed. If **FALSE**, then the right button of the pointer device is not being pressed. If the RightButton field of the EFI_SIMPLE_POINTER_MODE structure is **FALSE**, then this field is not valid, and must be ignored.

Description

The GetState() function retrieves the current state of a pointer device. This includes information on the buttons associated with the pointer device and the distance that each of the axes associated with the pointer device has been moved. If the state of the pointer device has not changed since the last call to GetState(), then EFI_NOT_READY is returned. If the state of the pointer device has changed since the last call to GetState(), then the state information is placed in State, and EFI_SUCCESS is returned. If a device error occurs while attempting to retrieve the state information, then EFI_DEVICE_ERROR is returned.

Status Codes Returned

EFI_SUCCESS	The state of the pointer device was returned in State.
EFI_NOT_READY	The state of the pointer device has not changed since the last call to GetState().
EFI_DEVICE_ERROR	A device error occurred while attempting to retrieve the pointer device's current state.

12.6 EFI Simple Pointer Device Paths

An *EFI Simple Pointer Device Paths* must be installed on a handle for its services to be available to drivers and applications written to this specification. In addition to the EFI_SIMPLE_POINTER_PROTOCOL, an *EFI Device Path Protocol* must also be installed on the same handle. *EFI Device Path Protocol* for a detailed description of the EFI_DEVICE_PATH_PROTOCOL.

A device path describes the location of a hardware component in a system from the processor's point of view. This includes the list of busses that lie between the processor and the pointer controller. The UEFI Specification takes advantage of the ACPI Specification to name system components. The following set of examples efi-device-path-protocolshows sample device paths for a PS/2* mouse, a serial mouse, and a USB mouse.

The Table below shows an example device path for a PS/2 mouse that is located behind a PCI to ISA bridge that is located at PCI device number 0x07 and PCI function 0x00, and is directly attached to a PCI root bridge. This device path consists of an ACPI Device Path Node for the PCI Root Bridge, a PCI Device Path Node for the PCI to ISA bridge, an ACPI Device Path Node for the PS/2 mouse, and a Device Path End Structure. The _HID and _UID of the first ACPI Device Path Node must match the ACPI table description of the PCI Root Bridge. The shorthand notation for this device path is:

```
ACPI(PNP0A03,0)/PCI(7,0)/ACPI(PNP0F03,0):
```

Table 12.20: PS/2 Mouse Device Path

Byte Offset	Byte Length	Data	Description
0x00	0x01	0x02	**Generic Device Path Header** - Type ACPI Device Path
0x01	0x01	0x01	Sub type - ACPI Device Path
0x02	0x02	0x0C	Length - 0x0C bytes
0x04	0x04	0x41D0, 0x0A03	_HID PNP0A03 - 0x41D0 represents a compressed string 'PNP' and is in the low order bytes. The compression method is described in the ACPI Specification.
0x08	0x04	0x0000	_UID
0x0C	0x01	0x01	**Generic Device Path Header** - Type Hardware Device Path
0x0D	0x01	0x01	Sub type - PCI
0x0E	0x02	0x06	Length - 0x06 bytes
0x10	0x01	0x00	PCI Function
0x11	0x01	0x07	PCI Device
0x12	0x01	0x02	**Generic Device Path Header** - Type ACPI Device Path
0x13	0x01	0x01	Sub type - ACPI Device Path
0x14	0x02	0x0C	Length - 0x0C bytes
0x16	0x04	0x41D0, 0x0F03	_HID PNP0A03 - 0x41D0 represents a compressed string 'PNP' and is in the low order bytes. The compression method is described in the ACPI Specification.
0x1A	0x04	0x0000	_UID
0x1E	0x01	0x7F	Generic Device Path Header - Type End of Hardware Device Path
0x1F	0x01	0xFF	Sub type - End of Entire Device Path
0x20	0x02	0x04	Length - 0x04 bytes

Serial Mouse Device Path shows an example device path for a serial mouse that is located on COM 1 behind a PCI to ISA bridge that is located at PCI device number 0x07 and PCI function 0x00. The PCI to ISA bridge is directly attached to a PCI root bridge, and the communications parameters for COM 1 are 1200 baud, no parity, 8 data bits, and 1 stop bit. This device path consists of an ACPI Device Path Node for the PCI Root Bridge, a PCI Device Path Node for the PCI to ISA bridge, an ACPI Device Path Node for COM 1, a UART Device Path Node for the communications parameters, an ACPI Device Path Node for the serial mouse, and a Device Path End Structure. The _HID and _UID of the first ACPI Device Path Node must match the ACPI table description of the PCI Root Bridge. The shorthand notation for this device path is:

```
ACPI(PNP0A03,0)/PCI(7,0)/ACPI(PNP0501,0)/UART(1200,N,8,1)/ACPI(PNP0F01,0)
```

Table 12.21: Serial Mouse Device Path

Byte Offset	**Byte Length**	**Data**	**Description**
0x00	0x01	0x02	**Generic Device Path Header** - Type ACPI Device Path
0x01	0x01	0x01	Sub type - ACPI Device Path
0x02	0x02	0x0C	Length - 0x0C bytes
0x04	0x04	0x41D0, | 0x0A03	_HID PNP0A03 - 0x41D0 represents the compressed string ‘PNP’ and is encoded in the low order bytes. The compression method is described in the ACPI Specification.
0x08	0x04	0x0000	_UID
0x0C	0x01	0x01	**Generic Device Path Header** - Type Hardware Device Path
0x0D	0x01	0x01	Sub type - PCI
0x0E	0x02	0x06	Length - 0x06 bytes
0x10	0x01	0x00	PCI Function
0x11	0x01	0x07	PCI Device
0x12	0x01	0x02	**Generic Device Path Header** - Type ACPI Device Path
0x13	0x01	0x01	Sub type - ACPI Device Path
0x14	0x02	0x0C	Length - 0x0C bytes
0x16	0x04	0x41D0, 0x0501	_HID PNP0501 - 0x41D0 represents the compressed string ‘PNP’ and is encoded in the low order bytes. The compression method is described in the ACPI Specification.
0x1A	0x04	0x0000	_UID
0x1E	0x01	0x03	**Generic Device Path Header** - Messaging Device Path
0x1F	0x01	0x0E	Sub type - UART Device Path
0x20	0x02	0x13	Length - 0x13 bytes
0x22	0x04	0x00	Reserved
0x26	0x08	1200	Baud Rate
0x2E	0x01	0x08	Data Bits
0x2F	0x01	0x01	Parity
0x30	0x01	0x01	Stop Bits
0x31	0x01	0x02	**Generic Device Path Header** - Type ACPI Device Path
0x32	0x01	0x01	Sub type - ACPI Device Path
0x33	0x02	0x0C	Length - 0x0C bytes
0x35	0x04	0x41D0, 0x0F01	_HID PNP0F01 - 0x41D0 represents the compressed string ‘PNP’ and is encoded in the low order bytes. The compression method is described in the ACPI Specification.
0x39	0x04	0x0000	_UID
0x3D	0x01	0x7F	**Generic Device Path Header** - Type End of Hardware Device Path
0x3E	0x01	0xFF	Sub type - End of Entire Device Path
0x3F	0x02	0x04	Length - 0x04 bytes

See *USB Mouse Device Path* shows an example device path for a USB mouse that is behind a PCI to USB host controller that is located at PCI device number 0x07 and PCI function 0x02. The PCI to USB host controller is directly attached to a PCI root bridge. This device path consists of an ACPI Device Path Node for the PCI Root Bridge, a PCI Device Path Node for the PCI to USB controller, a USB Device Path Node, and a Device Path End Structure. The _HID and _UID of the first ACPI Device Path Node must match the ACPI table description of the PCI Root Bridge. The shorthand notation for this device path is:

```
ACPI(PNP0A03,0)/PCI(7,2)/USB(0,0)
```

Table 12.22: USB Mouse Device Path

Byte Offset	Byte Length	Data	Description
0x00	0x01	0x02	**Generic Device Path Header** - Type ACPI Device Path
0x01	0x01	0x01	Sub type - ACPI Device Path
0x02	0x02	0x0C	Length - 0x0C bytes
0x04	0x04	0x41D0, 0x0A03	_HID PNP0A03 - 0x41D0 represents a compressed string ‘PNP’ and is in the low order bytes.

0x1A	0x02	0x04	Length - 0x04 bytes

12.7 Absolute Pointer Protocol

This section defines the Absolute Pointer Protocol and a detailed description of the *EFI_ABSOLUTE_POINTER_PROTOCOL* . The intent of this section is to specify a simple method for accessing absolute pointer devices. This would include devices like touch screens, and digitizers.

The *EFI_ABSOLUTE_POINTER_PROTOCOL* allows information about a pointer device to be retrieved. This would include the status of buttons and the coordinates of the pointer device on the last time it was activated. This protocol is attached to the device handle of an absolute pointer device, and can be used for input from the user in the preboot environment.

Supported devices may return 1, 2, or 3 axis of information. The Z axis may optionally be used to return pressure data measurements derived from user pen force.

All supported devices must support a touch-active status. Supported devices may optionally support a second input button, for example a pen side-button.

12.7.1 EFI_ABSOLUTE_POINTER_PROTOCOL

Summary

Provides services that allow information about an absolute pointer device to be retrieved.

GUID

```
#define EFI_ABSOLUTE_POINTER_PROTOCOL_GUID \
 {0x8D59D32B, 0xC655, 0x4AE9, \
  {0x9B, 0x15, 0xF2, 0x59, 0x04, 0x99, 0x2A, 0x43}}
```

Protocol Interface Structure

```
typedef struct _EFI_ABSOLUTE_POINTER_PROTOCOL {
 EFI_ABSOLUTE_POINTER_RESET                     Reset;
 EFI_ABSOLUTE_POINTER_GET_STATE                 GetState;
 EFI_EVENT                                      WaitForInput;
 EFI_ABSOLUTE_POINTER_MODE                      *Mode;
} EFI_ABSOLUTE_POINTER_PROTOCOL;
```

Parameters

Reset
Resets the pointer device. See the *Reset()* function description.

GetState
Retrieves the current state of the pointer device. See the *GetState()* function description.

WaitForInput
Event to use with *WaitForEvent()* to wait for input from the pointer device.

Mode
Pointer to EFI_ABSOLUTE_POINTER_MODE data. The type EFI_ABSOLUTE_POINTER_MODE is defined in "Related Definitions" below.

Related Definitions

```
//*******************************************************
// EFI_ABSOLUTE_POINTER_MODE
//*******************************************************
typedef struct {
 UINT64                    AbsoluteMinX;
 UINT64                    AbsoluteMinY;
 UINT64                    AbsoluteMinZ;
 UINT64                    AbsoluteMaxX;
 UINT64                    AbsoluteMaxY;
 UINT64                    AbsoluteMaxZ;
 UINT32                    Attributes;
} EFI_ABSOLUTE_POINTER_MODE;
```

The following data values in the EFI_ABSOLUTE_POINTER_MODE interface are read-only and are changed by using the appropriate interface functions:

AbsoluteMinX
The Absolute Minimum of the device on the x-axis

AbsoluteMinY
The Absolute Minimum of the device on the y -axis.

AbsoluteMinZ
The Absolute Minimum of the device on the z-axis.

AbsoluteMaxX
The Absolute Maximum of the device on the x-axis. If 0, and the AbsoluteMinX is 0, then the pointer device does not support a x-axis.

AbsoluteMaxY
The Absolute Maximum of the device on the y -axis. If 0, and the AbsoluteMinY is 0, then the pointer device does not support a y-axis.

AbsoluteMaxZ
The Absolute Maximum of the device on the z-axis. If 0, and the AbsoluteMinZ is 0, then the pointer device does not support a z-axis.

Attributes
The following bits are set as needed (or'd together) to indicate the capabilities of the device supported. The remaining bits are undefined and should be returned as 0.

```
#define EFI_ABSP_SupportsAltActive     0x00000001
#define EFI_ABSP_SupportsPressureAsZ   0x00000002

EFI_ABSP_SupportsAltActive
 If set, indicates this device supports an alternate button input.

EFI_ABSP_SupportsPressureAsZ
 If set, indicates this device returns pressure data in parameter CurrentZ.
```

The driver is not permitted to return all zeros for all three pairs of Min and Max as this would indicate no axis supported.

Description

The EFI_ABSOLUTE_POINTER_PROTOCOL provides a set of services for a pointer device that can be used as an input device from an application written to this specification. The services include the ability to reset the pointer device, retrieve the state of the pointer device, and retrieve the capabilities of the pointer device. In addition certain data items describing the device are provided.

12.7.2 EFI_ABSOLUTE_POINTER_PROTOCOL.Reset()

Summary

Resets the pointer device hardware.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_ABSOLUTE_POINTER_RESET) (
 IN EFI_ABSOLUTE_POINTER_PROTOCOL           *This,
 IN BOOLEAN                                 ExtendedVerification
 );
```

Parameters

This
A pointer to the *EFI_ABSOLUTE_POINTER_PROTOCOL* instance. Type EFI_ABSOLUTE_POINTER_PROTOCOL is defined in this section.

ExtendedVerification

Indicates that the driver may perform a more exhaustive verification operation of the device during reset.

Description

This Reset() function resets the pointer device hardware. As part of initialization process, the firmware/device will make a quick but reasonable attempt to verify that the device is functioning. If the ExtendedVerification flag is **TRUE** the firmware may take an extended amount of time to verify the device is operating on reset. Otherwise the reset operation is to occur as quickly as possible.

The hardware verification process is not defined by this specification and is left up to the platform firmware or driver to implement.

Codes Returned

EFI_SUCCESS	The device was reset.
EFI_DEVICE_ERROR	The device is not functioning correctly and could not be reset.

12.7.3 EFI_ABSOLUTE_POINTER_PROTOCOL.GetState()

Summary

Retrieves the current state of a pointer device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_ABSOLUTE_POINTER_GET_STATE) (
 IN EFI_ABSOLUTE_POINTER_PROTOCOL           *This,
 OUT EFI_ABSOLUTE_POINTER_STATE             *State
 );
```

Parameters

This

A pointer to EFI_ABSOLUTE_POINTER_PROTOCOL instance. Type EFI_ABSOLUTE_POINTER_PROTOCOL is defined in *EFI_ABSOLUTE_POINTER_PROTOCOL* .

State

A pointer to the state information on the pointer device. Type EFI_ABSOLUTE_POINTER_STATE is defined in “Related Definitions” below.

Related Definitions

```
//*******************************************************
   // EFI_ABSOLUTE_POINTER_STATE
   //*******************************************************
   typedef struct {
    UINT64                 CurrentX;
    UINT64                 CurrentY;
    UINT64                 CurrentZ;
    UINT32                 ActiveButtons;
   } EFI_ABSOLUTE_POINTER_STATE;
```

CurrentX

The unsigned position of the activation on the x axis If the AboluteMinX and the AboluteMaxX fields of the

EFI_ABSOLUTE_POINTER_MODE structure are both 0, then this pointer device does not support an x-axis, and this field must be ignored.

CurrentY

The unsigned position of the activation on the y axis If the AboluteMinY and the AboluteMaxY fields of the EFI_ABSOLUTE_POINTER_MODE structure are both 0, then this pointer device does not support a y-axis, and this field must be ignored.

CurrentZ

The unsigned position of the activation on the z axis, or the pressure measurement. If the AboluteMinZ and the AboluteMaxZ fields of the EFI_ABSOLUTE_POINTER_MODE structure are both 0, then this pointer device does not support a z-axis, and this field must be ignored.

ActiveButtons

Bits are set to 1 in this structure item to indicate that device buttons are active.

Related Definitions

```
//*******************************
//definitions of bits within ActiveButtons
//*******************************
#define EFI_ABSP_TouchActive     0x00000001
#define EFI_ABS_AltActive        0x00000002

    EFI_ABSP_TouchActive  This bit is set if the touch sensor is active
    EFI_ABS_AltActive This bit is set if the alt sensor, such as pen-side button, is␣
↪active.
```

Description

The GetState() function retrieves the current state of a pointer device. This includes information on the active state associated with the pointer device and the current position of the axes associated with the pointer device. If the state of the pointer device has not changed since the last call to *GetState()* , then *EFI_NOT_READY* is returned. If the state of the pointer device has changed since the last call to *GetState()* , then the state information is placed in State, and *EFI_SUCCESS* is returned. If a device error occurs while attempting to retrieve the state information, then *EFI_DEVICE_ERROR* is returned.

Status Codes Returned

EFI_SUCCESS	The state of the pointer device was returned in *State* .
EFI_NOT_READY	The state of the pointer device has not changed since the last call to *GetState()* .
EFI_DEVICE_ERROR	A device error occurred while attempting to retrieve the pointer device's current state.

12.8 Serial I/O Protocol

This section defines the Serial I/O protocol. This protocol is used to abstract byte stream devices.

12.8.1 EFI_SERIAL_IO_PROTOCOL

Summary

This protocol is used to communicate with any type of character-based I/O device.

GUID

```
#define EFI_SERIAL_IO_PROTOCOL_GUID \
 {0xBB25CF6F,0xF1D4,0x11D2,\
 {0x9a,0x0c,0x00,0x90,0x27,0x3f,0xc1,0xfd}}
```

Revision Number

```
#define EFI_SERIAL_IO_PROTOCOL_REVISION      0x00010000
#define EFI_SERIAL_IO_PROTOCOL_REVISION1p1   0x00010001
```

Protocol Interface Structure

```
typedef struct {
 UINT32                       Revision;
 EFI_SERIAL_RESET             Reset;
 EFI_SERIAL_SET_ATTRIBUTES    SetAttributes;
 EFI_SERIAL_SET_CONTROL_BITS  SetControl;
 EFI_SERIAL_GET_CONTROL_BITS  GetControl;
 EFI_SERIAL_WRITE             Write;
 EFI_SERIAL_READ              Read;
 SERIAL_IO_MODE               *Mode;
 CONST EFI_GUID               *DeviceTypeGuid; // Revision 1.1
} EFI_SERIAL_IO_PROTOCOL;
```

Parameters

Revision
The revision to which the EFI_SERIAL_IO_PROTOCOL adheres. All future revisions must be backwards compatible. If a future version is not back wards compatible, it is not the same GUID.

Reset
Resets the hardware device.

SetAttributes
Sets communication parameters for a serial device. These include the baud rate, receive FIFO depth, transmit/receive time out, parity, data bits, and stop bit attributes.

SetControl
Sets the control bits on a serial device. These include Request to Send and Data Terminal Ready.

GetControl
Reads the status of the control bits on a serial device. These include Clear to Send, Data Set Ready, Ring Indicator, and Carrier Detect.

Write
Sends a buffer of characters to a serial device.

Read
Receives a buffer of characters from a serial device.

Mode
Pointer to SERIAL_IO_MODE data. Type SERIAL_IO_MODE is defined in "Related Definitions" below.

DeviceTypeGuid

Pointer to a GUID identifying the device connected to the serial port. This field is NULL when the protocol is installed by the serial port driver and may be populated by a platform driver for a serial port with a known device attached. The field will remain NULL if there is no platform serial device identification information available.

Related Definitions

```
//*******************************************************
// SERIAL_IO_MODE
//*******************************************************
typedef struct {
UINT32 ControlMask;

   // current Attributes
   UINT32           Timeout;
   UINT64           BaudRate;
   UINT32           ReceiveFifoDepth;
   UINT32           DataBits;
   UINT32           Parity;
   UINT32           StopBits;
} SERIAL_IO_MODE;
```

The data values in the SERIAL_IO_MODE are read-only and are updated by the code that produces the EFI_SERIAL_IO_PROTOCOL functions:

ControlMask

A mask of the Control bits that the device supports. The device must always support the Input Buffer Empty control bit.

Timeout

If applicable, the number of microseconds to wait before timing out a Read or Write operation.

BaudRate

If applicable, the current baud rate setting of the device; otherwise, baud rate has the value of zero to indicate that device runs at the device's designed speed.

ReceiveFifoDepth

The number of characters the device will buffer on input.

DataBits

The number of data bits in each character.

Parity

If applicable, this is the EFI_PARITY_TYPE that is computed or checked as each character is transmitted or received. If the device does not support parity the value is the default parity value.

StopBits

If applicable, the EFI_STOP_BITS_TYPE number of stop bits per character. If the device does not support stop bits the value is the default stop bit value.

```
//*******************************************************
// EFI_PARITY_TYPE
//*******************************************************
typedef enum {
 DefaultParity,
 NoParity,
 EvenParity,
 OddParity,
```

(continues on next page)

(continued from previous page)

```
 MarkParity,
 SpaceParity
} EFI_PARITY_TYPE;

//*******************************************************
// EFI_STOP_BITS_TYPE
//*******************************************************
typedef enum {
 DefaultStopBits,
 OneStopBit,         // 1 stop bit
 OneFiveStopBits,    // 1.5 stop bits
 TwoStopBits         // 2 stop bits
} EFI_STOP_BITS_TYPE;
```

Description

The Serial I/O protocol is used to communicate with UART-style serial devices. These can be standard UART serial ports in PC-AT systems, serial ports attached to a USB interface, or potentially any character-based I/O device.

The Serial I/O protocol can control byte I/O style devices from a generic device, to a device with features such as a UART. As such many of the serial I/O features are optional to allow for the case of devices that do not have UART controls. Each of these options is called out in the specific serial I/O functions.

The default attributes for all UART-style serial device interfaces are: 115,200 baud, a 1 byte receive FIFO, a 1,000,000 microsecond timeout per character, no parity, 8 data bits, and 1 stop bit. Flow control is the responsibility of the software that uses the protocol. Hardware flow control can be implemented through the use of the *EFI_SERIAL_IO_PROTOCOL.GetControl()* and *EFI_SERIAL_IO_PROTOCOL.SetControl()* functions (described below) to monitor and assert the flow control signals. The XON/XOFF flow control algorithm can be implemented in software by inserting XON and XOFF characters into the serial data stream as required.

Special care must be taken if a significant amount of data is going to be read from a serial device. Since UEFI drivers are polled mode drivers, characters received on a serial device might be missed. It is the responsibility of the software that uses the protocol to check for new data often enough to guarantee that no characters will be missed. The required polling frequency depends on the baud rate of the connection and the depth of the receive FIFO.

12.8.2 Serial Device Identification

Serial device identification is accomplished through the interaction of three distinct drivers. The serial port driver binds to the serial port hardware and produces the EFI_SERIAL_IO_PROTOCOL. At the time the protocol is produced the DeviceTypeGuid field is NULL.

During the UEFI Driver Binding process a platform driver, with a EFI_DRIVER_BINDING_PROTOCOL Version field in the range of 0xfffffff0 to 0xffffffff can check for the presence of the EFI_SERIAL_IO_PROTOCOL and any other necessary information in Supported() to check if the serial port instance is recognized for the purposes of provide serial device identification information. If the port instance is recognized then EFI_SUCCESS will be returned from Supported(). Since the driver binding Version field is higher than any device driver the platform's serial device identification driver binding instance will have Start() called. This function will write the DeviceTypeGuid with a value that identifies the attached serial device.

When the driver binding process continues the serial device driver can use the DeviceTypeGuid field to determine the serial device connected to the port is supported.

Serial device drivers for non-terminal devices that will co-exist with backwards-compatible terminal drivers must check that the EFI_SERIAL_IO_PROTOCOL Revision field is at least 0x00010001 and compare the DeviceTypeGuid in their driver binding Supported() function. Terminal drivers provide backwards compatibility by assuming a Terminal device is present when a protocol instance Revision is the original 0x00010000 value. Terminal drivers may also assume a Terminal device is present if the DeviceTypeGuid is NULL for cases where the platform does not provide serial identification information.

12.8.3 Serial Device Type GUIDs

```
#define EFI_SERIAL_TERMINAL_DEVICE_TYPE_GUID \
   { 0x6ad9a60f, 0x5815, 0x4c7c, \
   { 0x8a, 0x10, 0x50, 0x53, 0xd2, 0xbf, 0x7a, 0x1b } }
```

The EFI_SERIAL_TERMINAL_DEVICE_TYPE_GUID describes a serial terminal type device suitable for use as a UEFI console.

Vendors may define and use additional GUIDs for other serial device types.

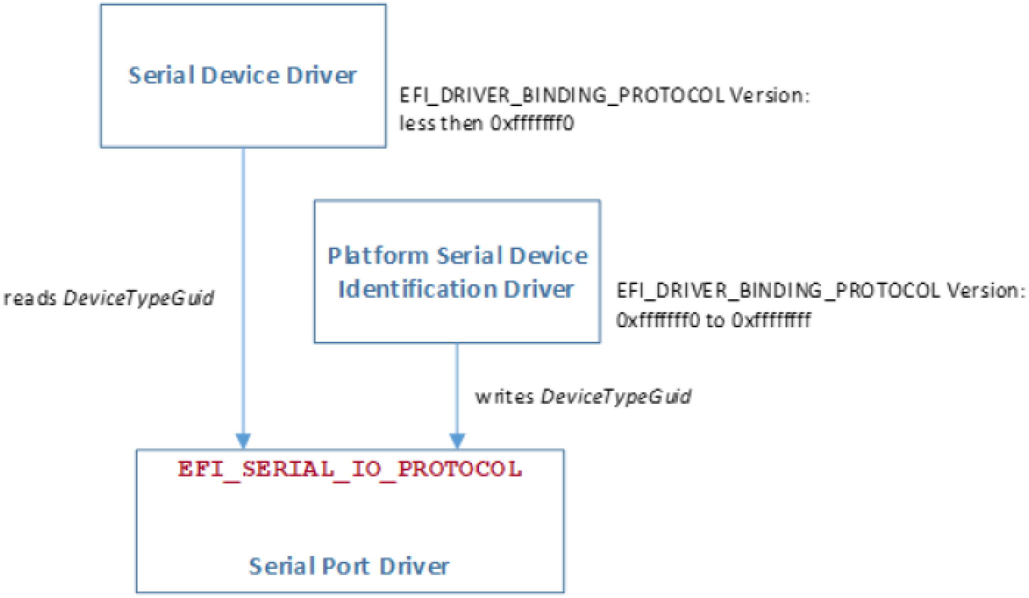

Fig. 12.1: Serial Device Identification Driver Relationships

12.8.3.1 EFI_SERIAL_IO_PROTOCOL.Reset()

Summary

Resets the serial device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SERIAL_RESET) (
 IN EFI_SERIAL_IO_PROTOCOL       *This
 );
```

Parameters

This

A pointer to the EFI_SERIAL_IO_PROTOCOL instance. Type EFI_SERIAL_IO_PROTOCOL is defined in *Serial I/O Protocol* .

Description

The Reset() function resets the hardware of a serial device.

Status Codes Returned

EFI_SUCCESS	The serial device was reset.
EFI_DEVICE_ERROR	The serial device could not be reset.

12.8.3.2 EFI_SERIAL_IO_PROTOCOL.SetAttributes()

Summary

Sets the baud rate, receive FIFO depth, transmit/receive time out, parity, data bits, and stop bits on a serial device.

```
EFI_STATUS
(EFIAPI *EFI_SERIAL_SET_ATTRIBUTES) (
 IN EFI_SERIAL_IO_PROTOCOL              *This,
 IN UINT64                              BaudRate,
 IN UINT32                              ReceiveFifoDepth,
 IN UINT32                              Timeout
 IN EFI_PARITY_TYPE                     Parity,
 IN UINT8                               DataBits,
 IN EFI_STOP_BITS_TYPE                  StopBits
 );
```

Parameters

This
A pointer to the EFI_SERIAL_IO_PROTOCOL instance. Type EFI_SERIAL_IO_PROTOCOL is defined in *Serial I/O Protocol*.

BaudRate
The requested baud rate. A BaudRate value of 0 will use the device's default interface speed.

ReceiveFifoDepth
The requested depth of the FIFO on the receive side of the serial interface. A ReceiveFifoDepth value of 0 will use the device's default FIFO depth.

Timeout
The requested time out for a single character in microseconds. This timeout applies to both the transmit and receive side of the interface. A Timeout value of 0 will use the device's default time out value.

Parity
The type of parity to use on this serial device. A Parity value of DefaultParity will use the device's default parity value. Type EFI_PARITY_TYPE is defined in "Related Definitions" in *Serial I/O Protocol*

DataBits
The number of data bits to use on this serial device. A DataBits value of 0 will use the device's default data bit setting.

StopBits
The number of stop bits to use on this serial device. A StopBits value of DefaultStopBits will use the device's

default number of stop bits. Type EFI_STOP_BITS_TYPE is defined in "Related Definitions" in *Serial I/O Protocol* .

Description

The SetAttributes() function sets the baud rate, receive-FIFO depth, transmit/receive time out, parity, data bits, and stop bits on a serial device.

The controller for a serial device is programmed with the specified attributes. If the Parity, DataBits, or StopBits values are not valid, then an error will be returned. If the specified BaudRate is below the minimum baud rate supported by the serial device, an error will be returned. The nearest baud rate supported by the serial device will be selected without exceeding the BaudRate parameter. If the specified ReceiveFifoDepth is below the smallest FIFO size supported by the serial device, an error will be returned. The nearest FIFO size supported by the serial device will be selected without exceeding the ReceiveFifoDepth parameter.

Status Codes Returned

EFI_SUCCESS	The new attributes were set on the serial device.
EFI_INVALID_PARAMETER	One or more of the attributes has an unsupported value.
EFI_DEVICE_ERROR	The serial device is not functioning correctly.

12.8.3.3 EFI_SERIAL_IO_PROTOCOL.SetControl()

Summary

Sets the control bits on a serial device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SERIAL_SET_CONTROL_BITS) (
 IN EFI_SERIAL_IO_PROTOCOL                  *This,
 IN UINT32                                  Control
 );
```

Parameters

This

A pointer to the EFI_SERIAL_IO_PROTOCOL instance. Type EFI_SERIAL_IO_PROTOCOL is defined in *Serial I/O Protocol* .

Control

Sets the bits of Control that are settable. See "Related Definitions" below.

Related Definitions

```
//*******************************************************
// CONTROL BITS
//*******************************************************

#define EFI_SERIAL_CLEAR_TO_SEND                0x0010

#define EFI_SERIAL_OUTPUT_BUFFER_EMPTY         0x0200
#define EFI_SERIAL_HARDWARE_LOOPBACK_ENABLE     0x1000
#define EFI_SERIAL_SOFTWARE_LOOPBACK_ENABLE     0x2000
#define EFI_SERIAL_HARDWARE_FLOW_CONTROL_ENABLE 0x4000
```

Description

The SetControl() function is used to assert or deassert the control signals on a serial device. The following signals are set according their bit settings:

- Request to Send
- Data Terminal Ready

Only the REQUEST_TO_SEND, DATA_TERMINAL_READY, HARDWARE_LOOPBACK_ENABLE, SOFTWARE_LOOPBACK_ENABLE, and HARDWARE_FLOW_CONTROL_ENABLE bits can be set with SetControl(). All the bits can be read with *EFI_SERIAL_IO_PROTOCOL.GetControl()* .

Status Codes Returned

EFI_SUCCESS	The new control bits were set on the serial device.
EFI_UNSUPPORTED	The serial device does not support this operation.
EFI_DEVICE_ERROR	The serial device is not functioning correctly.

12.8.3.4 EFI_SERIAL_IO_PROTOCOL.GetControl()

Summary

Retrieves the status of the control bits on a serial device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SERIAL_GET_CONTROL_BITS) (
 IN EFI_SERIAL_IO_PROTOCOL             *This,
 OUT UINT32                            *Control
 );
```

Parameters

This

A pointer to the EFI_SERIAL_IO_PROTOCOL instance. Type EFI_SERIAL_IO_PROTOCOL is defined in *Serial I/O Protocol* .

Control

A pointer to return the current control signals from the serial device. See “Related Definitions” below.

Related Definitions

```
//*******************************************************
   // CONTROL BITS
   //*******************************************************

   #define EFI_SERIAL_CLEAR_TO_SEND                   0x0010
```

(continues on next page)

(continued from previous page)

```

   #define EFI_SERIAL_CARRIER_DETECT                  0x0080
   #define EFI_SERIAL_REQUEST_TO_SEND                 0x0002
   #define EFI_SERIAL_DATA_TERMINAL_READY             0x0001
   #define EFI_SERIAL_INPUT_BUFFER_EMPTY              0x0100
   #define EFI_SERIAL_OUTPUT_BUFFER_EMPTY             0x0200
   #define EFI_SERIAL_HARDWARE_LOOPBACK_ENABLE        0x1000
   #define EFI_SERIAL_SOFTWARE_LOOPBACK_ENABLE        0x2000
   #define EFI_SERIAL_HARDWARE_FLOW_CONTROL_ENABLE    0x4000
```

Description

The GetControl() function retrieves the status of the control bits on a serial device.

Status Codes Returned

EFI_SUCCESS	The control bits were read from the serial device.
EFI_DEVICE_ERROR	The serial device is not functioning correctly.

12.8.3.5 EFI_SERIAL_IO_PROTOCOL.Write()

Summary

Writes data to a serial device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SERIAL_WRITE) (
 IN EFI_SERIAL_IO_PROTOCOL           *This,
 IN OUT UINTN                        *BufferSize,
 IN VOID                             *Buffer
 );
```

Parameters

This

A pointer to the EFI_SERIAL_IO_PROTOCOL instance. Type EFI_SERIAL_IO_PROTOCOL is defined in See *Serial I/O Protocol* .

BufferSize

On input, the size of the Buffer. On output, the amount of data actually written.

Buffer

The buffer of data to write.

Description

The Write() function writes the specified number of bytes to a serial device. If a time out error occurs while data is being sent to the serial port, transmission of this buffer will terminate, and EFI_TIMEOUT will be returned. In all cases the number of bytes actually written to the serial device is returned in BufferSize.

Status Codes Returned

EFI_SUCCESS	The data was written.
EFI_DEVICE_ERROR	The device reported an error.
EFI_TIMEOUT	The data write was stopped due to a timeout.

12.8.3.6 EFI_SERIAL_IO_PROTOCOL.Read()

Summary

Reads data from a serial device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SERIAL_READ) (
 IN EFI_SERIAL_IO_PROTOCOL           *This,
 IN OUT UINTN                        *BufferSize,
 OUT VOID                            *Buffer
 );
```

Parameters

This

A pointer to the EFI_SERIAL_IO_PROTOCOL instance. Type EFI_SERIAL_IO_PROTOCOL is defined in See *Serial I/O Protocol* .

BufferSize

On input, the size of the Buffer. On output, the amount of data returned in Buffer.

Buffer

The buffer to return the data into.

Description

The Read() function reads a specified number of bytes from a serial device. If a time out error or an overrun error is detected while data is being read from the serial device, then no more characters will be read, and an error will be returned. In all cases the number of bytes actually read is returned in BufferSize.

Status Codes Returned

EFI_SUCCESS	The data was read.
EFI_DEVICE_ERROR	The serial device reported an error.
EFI_TIMEOUT	The operation was stopped due to a timeout or overrun.

12.9 Graphics Output Protocol

The goal of this section is to replace the functionality that currently exists with VGA hardware and its corresponding video BIOS. The Graphics Output Protocol is a software abstraction and its goal is to support any foreseeable graphics hardware and not require VGA hardware, while at the same time also lending itself to implementation on the current generation of VGA hardware.

Graphics output is important in the pre-boot space to support modern firmware features. These features include the display of logos, the localization of output to any language, and setup and configuration screens.

Graphics output may also be required as part of the startup of an operating system. There are potentially times in modern operating systems prior to the loading of a high performance OS graphics driver where access to graphics output device is required. The Graphics Output Protocol supports this capability by providing the EFI OS loader access to a hardware frame buffer and enough information to allow the OS to draw directly to the graphics output device.

The *EFI_GRAPHICS_OUTPUT_PROTOCOL* : supports three member functions to support the limited graphics needs of the pre-boot environment. These member functions allow the caller to draw to a virtualized frame buffer, retrieve the supported video modes, and to set a video mode. These simple primitives are sufficient to support the general needs of pre-OS firmware code.

The *EFI_GRAPHICS_OUTPUT_PROTOCOL* also exports enough information about the current mode for operating system startup software to access the linear frame buffer directly.

The interface structure for the Graphics Output protocol is defined in this section. A unique Graphics Output protocol must represent each video frame buffer in the system that is driven out to one or more video output devices.

12.9.1 Blt Buffer

The basic graphics operation in the EFI_GRAPHICS_OUTPUT_PROTOCOL is the Block Transfer or Blt. The Blt operation allows data to be read or written to the video adapter's video memory. The Blt operation abstracts the video adapters hardware implementation by introducing the concept of a software Blt buffer.

The frame buffer abstracts the video display as an array of pixels. Each pixels location on the video display is defined by its X and Y coordinates. The X coordinate represents a scan line. A scan line is a horizontal line of pixels on the display. The Y coordinate represents a vertical line on the display. The upper left hand corner of the video display is defined as (0, 0) where the notation (X, Y) represents the X and Y coordinate of the pixel. The lower right corner of the video display is represented by (Width -1, Height -1).

The software Blt buffer is structured as an array of pixels. Pixel (0, 0) is the first element of the software Blt buffer. The Blt buffer can be thought of as a set of scan lines. It is possible to convert a pixel location on the video display to the Blt buffer using the following algorithm: Blt buffer array index = Y * Width + X.

Each software Blt buffer entry represents a pixel that is comprised of a 32-bit quantity. The color components of Blt buffer pixels are in PixelBlueGreenRedReserved8BitPerColor format as defined by EFI_GRAPHICS_OUTPUT_BLT_PIXEL. The byte values for the red, green, and blue components represent the color intensity. This color intensity value range from a minimum intensity of 0 to maximum intensity of 255.

12.9.2 EFI_GRAPHICS_OUTPUT_PROTOCOL

Summary

Provides a basic abstraction to set video modes and copy pixels to and from the graphics controller's frame buffer. The linear address of the hardware frame buffer is also exposed so software can write directly to the video hardware.

GUID

```
#define EFI_GRAPHICS_OUTPUT_PROTOCOL_GUID \
 {0x9042a9de,0x23dc,0x4a38,\
  {0x96,0xfb,0x7a,0xde,0xd0,0x80,0x51,0x6a}}
```

Protocol Interface Structure

```
typedef struct EFI_GRAPHICS_OUTPUT_PROTCOL {
 EFI_GRAPHICS_OUTPUT_PROTOCOL_QUERY_MODE     QueryMode;
 EFI_GRAPHICS_OUTPUT_PROTOCOL_SET_MODE       SetMode;
 EFI_GRAPHICS_OUTPUT_PROTOCOL_BLT            Blt;
```

(continues on next page)

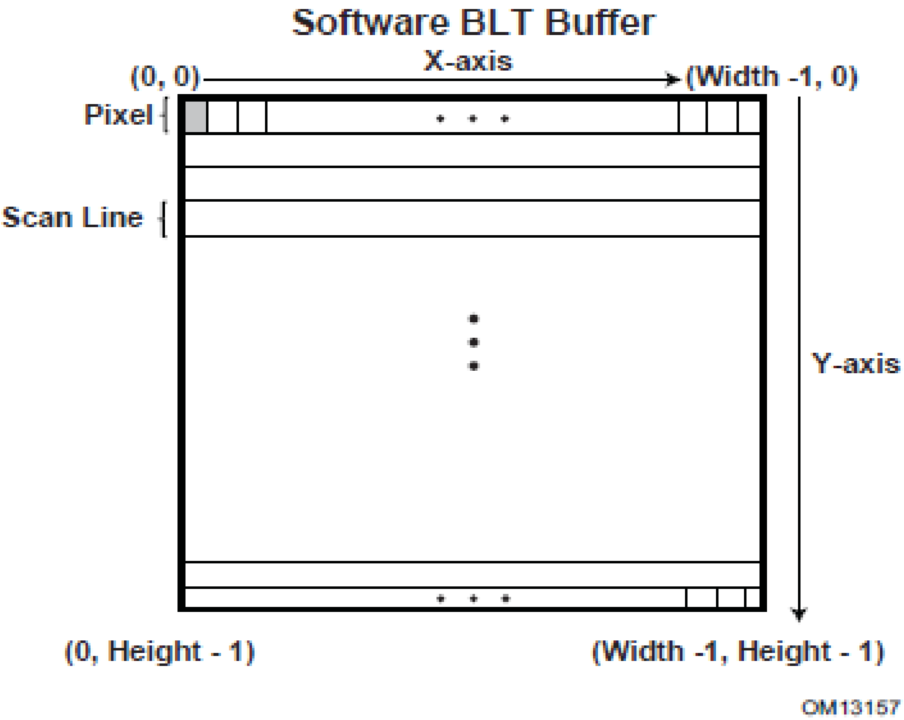

Fig. 12.2: Software BLT Buffer

(continued from previous page)

```
 EFI_GRAPHICS_OUTPUT_PROTOCOL_MODE           *Mode;
} EFI_GRAPHICS_OUTPUT_PROTOCOL;
```

Parameters

QueryMode
Returns information for an available graphics mode that the graphics device and the set of active video output devices supports.

SetMode
Set the video device into the specified mode and clears the visible portions of the output display to black.

Blt
Software abstraction to draw on the video device's frame buffer.

Mode
Pointer to EFI_GRAPHICS_OUTPUT_PROTOCOL_MODE data. Type EFI_GRAPHICS_OUTPUT_PROTOCOL_MODE is defined in "Related Definitions" below.

Related Definitions

```
 typedef struct {
  UINT32              RedMask;
  UINT32              GreenMask;
  UINT32              BlueMask;
  UINT32              ReservedMask;
 } EFI_PIXEL_BITMASK;

If a bit is set in RedMask, GreenMask, or BlueMask then those bits of the pixel␣
↪represent the corresponding color. Bits in RedMask, GreenMask, BlueMask, and␣
↪ReserverdMask must not over lap bit positions. The values for the red, green, and blue␣
↪components in the bit mask represent the color intensity. The color intensities must␣
↪increase as the color values for a each color mask increase with a minimum intensity␣
↪of all bits in a color mask clear to a maximum intensity of all bits in a color mask␣
↪set.
```

```
typedef enum {
  PixelRedGreenBlueReserved8BitPerColor,
  PixelBlueGreenRedReserved8BitPerColor,
  PixelBitMask,
  PixelBltOnly,
  PixelFormatMax
} EFI_GRAPHICS_PIXEL_FORMAT;
```

PixelRedGreenBlueReserved8BitPerColor
A pixel is 32-bits and byte zero represents red, byte one represents green, byte two represents blue, and byte three is reserved. This is the definition for the physical frame buffer. The byte values for the red, green, and blue components represent the color intensity. This color intensity value range from a minimum intensity of 0 to maximum intensity of 255.

PixelBlueGreenRedReserved8BitPerColor
A pixel is 32-bits and byte zero represents blue, byte one represents green, byte two represents red, and byte three is reserved. This is the definition for the physical frame buffer. The byte values for the red, green, and blue components represent the color intensity. This color intensity value range from a minimum intensity of 0 to maximum intensity of 255.

PixelBitMask

The pixel definition of the physical frame buffer is defined by EFI_PIXEL_BITMASK.

PixelBltOnly

This mode does not support a physical frame buffer.

PixelFormatMax

Valid EFI_GRAPHICS_PIXEL_FORMAT enum values are less than this value.

```
typedef struct {
 UINT32                    Version;
 UINT32                    HorizontalResolution;
 UINT32                    VerticalResolution;
 EFI_GRAPHICS_PIXEL_FORMAT PixelFormat;
 EFI_PIXEL_BITMASK         PixelInformation;
 UINT32                    PixelsPerScanLine;
} EFI_GRAPHICS_OUTPUT_MODE_INFORMATION;
```

Version

The version of this data structure. A value of zero represents the EFI_GRAPHICS_OUTPUT_MODE_INFORMATION structure as defined in this specification. Future version of this specification may extend this data structure in a backwards compatible way and increase the value of Version.

HorizontalResolution

The size of video screen in pixels in the X dimension.

VerticalResolution

The size of video screen in pixels in the Y dimension.

PixelFormat

Enumeration that defines the physical format of the pixel. A value of PixelBltOnly implies that a linear frame buffer is not available for this mode.

PixelInformation

This bit-mask is only valid if PixelFormat is set to PixelPixelBitMask. A bit being set defines what bits are used for what purpose such as Red, Green, Blue, or Reserved.

PixelsPerScanLine

Defines the number of pixel elements per video memory line. For performance reasons, or due to hardware restrictions, scan lines may be padded to an amount of memory alignment. These padding pixel elements are outside the area covered by *HorizontalResolution* and are not visible. For direct frame buffer access, this number is used as a span between starts of pixel lines in video memory. Based on the size of an individual pixel element and *PixelsPerScanline* , the offset in video memory from pixel element (x, y) to pixel element (x, y+1) has to be calculated as "sizeof(PixelElement) * PixelsPerScanLine", not "sizeof(PixelElement) * HorizontalResolution", though in many cases those values can coincide. This value can depend on video hardware and mode resolution. GOP implementation is responsible for providing accurate value for this field.

Note: *The following code sample is an example of the intended field usage*:

```
INTN
GetPixelElementSize (
 IN EFI_PIXEL_BITMASK   *PixelBits
 )
{
 INTN HighestPixel = -1;
```

(continues on next page)

(continued from previous page)

```
 INTN BluePixel;
 INTN RedPixel;
 INTN GreenPixel;
 INTN RsvdPixel;

 BluePixel = FindHighestSetBit (PixelBits->BlueMask);
 RedPixel = FindHighestSetBit (PixelBits->RedMask);
 GreenPixel = FindHighestSetBit (PixelBits->GreenMask);
 RsvdPixel = FindHighestSetBit (PixelBits->ReservedMask);

 HighestPixel = max (BluePixel, RedPixel);
 HighestPixel = max (HighestPixel, GreenPixel);
 HighestPixel = max (HighestPixel, RsvdPixel);

 return HighestPixel;
}

EFI_PHYSICAL_ADDRESS                NewPixelAddress;
EFI_PHYSICAL_ADDRESS                CurrentPixelAddress* ;
EFI_GRAPHICS_OUTPUT_MODE_INFORMATION   OutputInfo;
INTN                                PixelElementSize;

switch (OutputInfo.PixelFormat) {
 case PixelBitMask:
  PixelElementSize =
   GetPixelElementSize (&OutputInfo.PixelInformation);
  break;

 case PixelBlueGreenRedReserved8BitPerColor:
 case PixelRedGreenBlueReserved8BitPerColor:
  PixelElementSize =
  sizeof (EFI_GRAPHICS_OUTPUT_BLT_PIXEL);
  break;
}

//
// NewPixelAddress after execution points to the pixel
// positioned one line below the one pointed by
// CurrentPixelAddress
//
NewPixelAddress = CurrentPixelAddress +
        (PixelElementSize *
        OutputInfo.PixelsPerScanLine);
```

End of note code sample.

```
typedef struct {
  UINT32                                MaxMode;
  UINT32                                Mode;
  EFI_GRAPHICS_OUTPUT_MODE_INFORMATION     *Info;
 UINTN                                  SizeOfInfo;
  EFI_PHYSICAL_ADDRESS                  FrameBufferBase;
```

(continues on next page)

(continued from previous page)

```
  UINTN                                    FrameBufferSize;
} EFI_GRAPHICS_OUTPUT_PROTOCOL_MODE;
```

The EFI_GRAPHICS_OUTPUT_PROTOCOL_MODE is read-only and values are only changed by using the appropriate interface functions:

MaxMode
The number of modes supported by QueryMode() and EFI_GRAPHICS_OUTPUT_PROTOCOL.SetMode()_.

Mode
Current Mode of the graphics device. Valid mode numbers are 0 to MaxMode -1.

Info
Pointer to read-only EFI_GRAPHICS_OUTPUT_MODE_INFORMATION data.

SizeOfInfo
Size of Info structure in bytes. Future versions of this specification may increase the size of the EFI_GRAPHICS_OUTPUT_MODE_INFORMATION data.

FrameBufferBase
Base address of graphics linear frame buffer. Info contains information required to allow software to draw directly to the frame buffer without using Blt().Offset zero in FrameBufferBase represents the upper left pixel of the display.

FrameBufferSize
Amount of frame buffer needed to support the active mode as defined by *PixelsPerScanLine* x *VerticalResolution* x *PixelElementSize* .

Description

The EFI_GRAPHICS_OUTPUT_PROTOCOL provides a software abstraction to allow pixels to be drawn directly to the frame buffer. The EFI_GRAPHICS_OUTPUT_PROTOCOL is designed to be lightweight and to support the basic needs of graphics output prior to Operating System boot.

12.9.2.1 EFI_GRAPHICS_OUTPUT_PROTOCOL.QueryMode()

Summary

Returns information for an available graphics mode that the graphics device and the set of active video output devices supports.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_GRAPHICS_OUTPUT_PROTOCOL_QUERY_MODE) (
 IN EFI_GRAPHICS_OUTPUT_PROTOCOL             *This,
 IN UINT32                                   ModeNumber,
 OUT UINTN                                   *SizeOfInfo
 OUT EFI_GRAPHICS_OUTPUT_MODE_INFORMATION     **Info
 );
```

Parameters

This
The *EFI_GRAPHICS_OUTPUT_PROTOCOL* instance. Type EFI_GRAPHICS_OUTPUT_PROTOCOL is defined in this section.

ModeNumber

The mode number to return information on. The current mode and valid modes are read-only values in the Mode structure of the *EFI_GRAPHICS_OUTPUT_PROTOCOL* .

SizeOfInfo

A pointer to the size, in bytes, of the Info buffer.

Info

A pointer to a callee allocated buffer that returns information about ModeNumber.

Description

The QueryMode() function returns information for an available graphics mode that the graphics device and the set of active video output devices supports. If ModeNumber is not between 0 and MaxMode - 1, then EFI_INVALID_PARAMETER is returned. MaxMode is available from the Mode structure of the EFI_GRAPHICS_OUTPUT_PROTOCOL.

The size of the Info structure should never be assumed and the value of SizeOfInfo is the only valid way to know the size of Info.

If the EFI_GRAPHICS_OUTPUT_PROTOCOL is installed on the handle that represents a single video output device, then the set of modes returned by this service is the subset of modes supported by both the graphics controller and the video output device.

If the EFI_GRAPHICS_OUTPUT_PROTOCOL is installed on the handle that represents a combination of video output devices, then the set of modes returned by this service is the subset of modes supported by the graphics controller and the all of the video output devices represented by the handle.

Status Codes Returned

EFI_SUCCESS	Valid mode information was returned.
EFI_DEVICE_ERROR	A hardware error occurred trying to retrieve the video mode.
EFI_INVALID_PARAMETER	*ModeNumber* is not valid.

12.9.2.2 EFI_GRAPHICS_OUTPUT_PROTOCOL.SetMode()

Summary

Set the video device into the specified mode and clears the visible portions of the output display to black.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_GRAPHICS_OUTPUT_PROTOCOL_SET_MODE) (
 IN EFI_GRAPHICS_OUTPUT_PROTOCOL                *This,
 IN UINT32                                      ModeNumber
 );
```

Parameters

This

The *EFI_GRAPHICS_OUTPUT_PROTOCOL* instance. Type EFI_GRAPHICS_OUTPUT_PROTOCOL is defined in this section.

ModeNumber

Abstraction that defines the current video mode. The current mode and valid modes are read-only values in the Mode structure of the *EFI_GRAPHICS_OUTPUT_PROTOCOL* .

Description

This SetMode() function sets the graphics device and the set of active video output devices to the video mode specified by ModeNumber. If ModeNumber is not supported EFI_UNSUPPORTED is returned.

If a device error occurs while attempting to set the video mode, then EFI_DEVICE_ERROR is returned. Otherwise, the graphics device is set to the requested geometry, the set of active output devices are set to the requested geometry, the visible portion of the hardware frame buffer is cleared to black, and EFI_SUCCESS is returned.

Status Codes Returned

EFI_SUCCESS	The graphics mode specified by ModeNumber was selected.
EFI_DEVICE_ERROR	The device had an error and could not complete the request.
EFI_UNSUPPORTED	ModeNumber is not supported by this device.

12.9.2.3 EFI_GRAPHICS_OUTPUT_PROTOCOL.Blt()

Summary

Blt a rectangle of pixels on the graphics screen. Blt stands for BLock Transfer.

Prototype

```
typedef struct {
 UINT8                        Blue;
 UINT8                        Green;
 UINT8                        Red;
 UINT8                        Reserved;
} EFI_GRAPHICS_OUTPUT_BLT_PIXEL;

typedef enum {
 EfiBltVideoFill,
 EfiBltVideoToBltBuffer,
 EfiBltBufferToVideo,
 EfiBltVideoToVideo,
 EfiGraphicsOutputBltOperationMax
} EFI_GRAPHICS_OUTPUT_BLT_OPERATION;

typedef
EFI_STATUS
(EFIAPI *EFI_GRAPHICS_OUTPUT_PROTOCOL_BLT) (
 IN EFI_GRAPHICS_OUTPUT_PROTOCOL               *This,
 IN OUT EFI_GRAPHICS_OUTPUT_BLT_PIXEL          *BltBuffer, OPTIONAL
 IN EFI_GRAPHICS_OUTPUT_BLT_OPERATION          BltOperation,
 IN UINTN                                      SourceX,
 IN UINTN                                      SourceY,
 IN UINTN                                      DestinationX,
 IN UINTN                                      DestinationY,
 IN UINTN                                      Width,
 IN UINTN                                      Height,
 IN UINTN                                      Delta OPTIONAL
 );
```

Parameters

This

The *EFI_GRAPHICS_OUTPUT_PROTOCOL* instance.

BltBuffer

The data to transfer to the graphics screen. Size is at least Width*Height*sizeof(EFI_GRAPHICS_OUTPUT_BLT_PIXEL).

BltOperation

The operation to perform when copying BltBuffer on to the graphics screen.

SourceX

The X coordinate of the source for the BltOperation. The origin of the screen is 0, 0 and that is the upper left-hand corner of the screen. SourceY The Y coordinate of the source for the BltOperation. The origin of the screen is 0, 0 and that is the upper left-hand corner of the screen.

DestinationX

The X coordinate of the destination for the BltOperation. The origin of the screen is 0, 0 and that is the upper left-hand corner of the screen.

DestinationY

The Y coordinate of the destination for the BltOperation. The origin of the screen is 0, 0 and that is the upper left-hand corner of the screen.

Width

The width of a rectangle in the blt rectangle in pixels. Each pixel is represented by an EFI_GRAPHICS_OUTPUT_BLT_PIXEL element.

Height

The height of a rectangle in the blt rectangle in pixels. Each pixel is represented by an EFI_GRAPHICS_OUTPUT_BLT_PIXEL element.

Delta

Not used for EfiBltVideoFill or the EfiBltVideoToVideo operation. If a Delta of zero is used, the entire BltBuffer is being operated on. If a subrectangle of the BltBuffer is being used then Delta represents the number of bytes in a row of the BltBuffer.

Description

The Blt() function is used to draw the BltBuffer rectangle onto the video screen.

The BltBuffer represents a rectangle of Height by Width pixels that will be drawn on the graphics screen using the operation specified by BltOperation. The Delta value can be used to enable the BltOperation to be performed on a sub-rectangle of the BltBuffer.

Blt Operation Table describes the BltOperations that are supported on rectangles. Rectangles have coordinates (left, upper) (right, bottom):

Table 12.32: Blt Operation Table

Blt Operation	Operation
Efibltvideofill	Write data from the BltBuffer pixel (0,0) directly to every pixel of the video display rectangle (DestinationX, DestinationY) (DestinationX + Width, DestinationY + Height). Only one pixel will be used from the BltBuffer. Delta is NOT used.
Efibltvideoto-bltbuffer	Read data from the video display rectangle (SourceX, SourceY) (SourceX + Width, SourceY + Height) and place it in the BltBuffer rectangle (DestinationX, DestinationY) (DestinationX + Width, DestinationY + Height). If DestinationX or DestinationY is not zero then Delta must be set to the length in bytes of a row in the BltBuffer.

continues on next page

Table 12.32 – continued from previous page

Efibltbuffertovideo	Write data from the BltBuffer rectangle (SourceX, SourceY) (SourceX + Width, SourceY + Height) directly to the video display rectangle (DestinationX, DestinationY) (DestinationX + Width, DestinationY + Height). If SourceX or SourceY is not zero then Delta must be set to the length in bytes of a row in the BltBuffer.
Efi-bltvideotovideo	Copy from the video display rectangle (SourceX, SourceY) (SourceX + Width, SourceY + Height) to the video display rectangle(DestinationX, DestinationY) (DestinationX + Width, DestinationY + Height. The BltBuffer and Delta are not used in this mode. There is no limitation on the overlapping of the source and destination rectangles.

Status Codes Returned

EFI_SUCCESS	BltBuffer was drawn to the graphics screen.
EFI_INVALID_PARAMETER	BltOperation is not valid.
EFI_DEVICE_ERROR	The device had an error and could not complete the request.

12.9.2.4 EFI_EDID_DISCOVERED_PROTOCOL

Summary

This protocol contains the EDID information retrieved from a video output device.

GUID

```
#define EFI_EDID_DISCOVERED_PROTOCOL_GUID \
 {0x1c0c34f6,0xd380,0x41fa,\
  {0xa0,0x49,0x8a,0xd0,0x6c,0x1a,0x66,0xaa}}
```

Protocol Interface Structure

```
typedef struct {
 UINT32                                SizeOfEdid;
 UINT8                                 *Edid;
} EFI_EDID_DISCOVERED_PROTOCOL;
```

Parameter

SizeOfEdid

The size, in bytes, of the Edid buffer. 0 if no EDID information is available from the video output device. Otherwise, it must be a minimum of 128 bytes.

Edid

A pointer to a read-only array of bytes that contains the EDID information for a video output device. This pointer is NULL if no EDID information is available from the video output device. The minimum size of a valid Edid buffer is 128 bytes. EDID information is defined in the E-EDID EEPROM specification published by VESA (*www.vesa.org <www.vesa.org>__*)

Description

EFI_EDID_DISCOVERED_PROTOCOL represents the EDID information that is returned from a video output device. If the video output device does not contain any EDID information, then the SizeOfEdid field must set to zero and the Edid field must be set to NULL. The EFI_EDID_DISCOVERED_PROTOCOL must be placed on every child handle that represents a possible video output device. The EFI_EDID_DISCOVERED_PROTOCOL is never placed on child handles that represent combinations of two or more video output devices.

12.9.2.5 EFI_EDID_ACTIVE_PROTOCOL

Summary

This protocol contains the EDID information for an active video output device. This is either the EDID information retrieved from the EFI_EDID_OVERRIDE_PROTOCOL if an override is available, or an identical copy of the EDID information from the EFI_EDID_DISCOVERED_PROTOCOL if no overrides are available.

GUID

```
#define EFI_EDID_ACTIVE_PROTOCOL_GUID \
 {0xbd8c1056,0x9f36,0x44ec,\
  {0x92,0xa8,0xa6,0x33,0x7f,0x81,0x79,0x86}}
```

Protocol Interface Structure

```
typedef struct {
 UINT32                             SizeOfEdid;
 UINT8                              *Edid;
} EFI_EDID_ACTIVE_PROTOCOL;
```

Parameter

SizeOfEdid
The size, in bytes, of the Edid buffer. 0 if no EDID information is available from the video output device. Otherwise, it must be a minimum of 128 bytes.

Edid
A pointer to a read-only array of bytes that contains the EDID information for an active video output device. This pointer is NULL if no EDID information is available for the video output device. The minimum size of a valid Edid buffer is 128 bytes. EDID information is defined in the E-EDID EEPROM specification published by VESA (*www.vesa.org*).

Description

When the set of active video output devices attached to a frame buffer are selected, the EFI_EDID_ACTIVE_PROTOCOL must be installed onto the handles that represent the each of those active video output devices. If the EFI_EDID_OVERRIDE_PROTOCOL has override EDID information for an active video output device, then the EDID information specified by GetEdid() is used for the EFI_EDID_ACTIVE_PROTOCOL. Otherwise, the EDID information from the EFI_EDID_DISCOVERED_PROTOCOL is used for the EFI_EDID_ACTIVE_PROTOCOL. Since all EDID information is read-only, it is legal for the pointer associated with the EFI_EDID_ACTIVE_PROTOCOL to be the same as the pointer associated with the EFI_EDID_DISCOVERED_PROTOCOL when no overrides are present.

12.9.2.6 EFI_EDID_OVERRIDE_PROTOCOL

Summary

This protocol is produced by the platform to allow the platform to provide EDID information to the producer of the Graphics Output protocol.

GUID

```
#define EFI_EDID_OVERRIDE_PROTOCOL_GUID \
 {0x48ecb431,0xfb72,0x45c0,\
  {0xa9,0x22,0xf4,0x58,0xfe,0x04,0x0b,0xd5}}
```

Protocol Interface Structure

```
typedef struct _EFI_EDID_OVERRIDE_PROTOCOL {
 EFI_EDID_OVERRIDE_PROTOCOL_GET_EDID      GetEdid;
  } EFI_EDID_OVERRIDE_PROTOCOL;
```

Parameter

GetEdid

Returns EDID values and attributes that the Video BIOS must use

Description

This protocol is produced by the platform to allow the platform to provide EDID information to the producer of the Graphics Output protocol.

12.9.2.7 EFI_EDID_OVERRIDE_PROTOCOL.GetEdid()

Summary

Returns policy information and potentially a replacement EDID for the specified video output device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI \*EFI_EDID_OVERRIDE_PROTOCOL_GET_EDID) (
 IN   EFI_EDID_OVERRIDE_PROTOCOL                     *This,
 IN   EFI_HANDLE                                     *ChildHandle,
 OUT  UINT32                                         *Attributes,
 OUT UINTN                                           *EdidSize,
 OUT UINT8                                           **Edid
 );
```

Parameters

This

The *EFI_EDID_OVERRIDE_PROTOCOL.GetEdid()* instance. Type EFI_EDID_OVERRIDE_PROTOCOL is defined in *Rules for PCI/AGP Devices* .

ChildHandle

A pointer to a child handle that represents a possible video output device.

Attributes

A pointer to the attributes associated with ChildHandle video output device.

EdidSize

A pointer to the size, in bytes, of the Edid buffer.

Edid

A pointer to the callee allocated buffer that contains the EDID information associated with ChildHandle. If EdidSize is 0, then a pointer to NULL is returned.

Note: the (EFI_HANDLE *) type of the "ChildHandle" parameter is an historical typing error in the UEFI specification. To match existent practice however, implementors and callers of the protocol are now expected to conform to the declaration of the parameter as written. That is, callers must pass the address of an EFI_HANDLE object as "ChildHandle", and implementors must dereference "ChildHandle" for finding the EFI_HANDLE object.*

Related Definitions

```
#define EFI_EDID_OVERRIDE_DONT_OVERRIDE 0x01
#define EFI_EDID_OVERRIDE_ENABLE_HOT_PLUG 0x02
```

Table 12.34: Attributes Definition Table

Attribute Bit	Edid-Size	Operation
EFI_EDID_OVERRIDE_DONT_OVERRIDE=0	0	No override support device.
EFI_EDID_OVERRIDE_DONT_OVERRIDE=0	!= 0	Always use returned display device.
EFI_EDID_OVERRIDE_DONT_OVERRIDE!=0	0	No override support for the display device.
EFI_EDID_OVERRIDE_DONT_OVERRIDE!=0	!= 0	Only use returned override EDID if the display device has no EDID or the EDID is incorrect. Otherwise, use the EDID from the display device.
EFI_EDID_OVERRIDE_ENABLE_HOT_PLUG=0	0	No hot plug support for the display device. AGraphics Output protocol will not be installed if no display device is not present.
EFI_EDID_OVERRIDE_ENABLE_HOT_PLUG=0	!= 0	No hot plug support for the display device. The returned override EDID should be used according to the EFI_EDID_OVERRIDE_DONT_OVERRIDE attribute bit if the display device is present.
EFI_EDID_OVERRIDE_ENABLE_HOT_PLUG!=0	0	Invalid. The client of this protocol will not enable hot plug for the display device, and a Graphics Output protocol will not be installed if no other display is present.
EFI_EDID_OVERRIDE_ENABLE_HOT_PLUG!=0	!= 0	Enable hot plug for the display device. A Graphics Output protocol will be installed even if the display device is not present.

Description

This protocol is optionally provided by the platform to override or provide EDID information and/or output device display properties to the producer of the Graphics Output protocol. If ChildHandle does not represent a video output device, or there are no override for the video output device specified by ChildHandle, then EFI_UNSUPPORTED is returned. Otherwise, the Attributes, EdidSize, and Edid parameters are returned along with a status of EFI_SUCCESS. The *Attributes Definition Table* defines the behavior for the combinations of the Attribute and EdidSize parameters when EFI_SUCCESS is returned.

Status Codes Returned

EFI_SUCCESS	Valid over rides returned for ChildHandle.
EFI_UNSUPPORTED	ChildHandle has no over rides.

12.10 Rules for PCI/AGP Devices

A UEFI driver that produces the Graphics Output Protocol must follow the UEFI driver model, produce an *EFI Driver Binding Protocol* , and follow the rules on implementing the Supported() *EFI_DRIVER_BINDING_PROTOCOL.Supported()* , *efi-driver-binding-protocol-Start-protocols-uefi-driver-model* , and :ref:efi-driver-binding-protocol-Stop-protocols-uefi-driver-model` . The Start() function must not update the video output device in any way that is visible to the user. The Start() function must create child handle for each physical video output device and each supported combination of video output devices. The driver must retrieve the EDID information from each physical video output device and produce a *EFI_EDID_DISCOVERED_PROTOCOL* on the child handle that corresponds each physical video output device. The following summary describes the common initialization steps for a driver that produces the EFI_GRAPHICS_OUTPUT_PROTOCOL. This summary assumes the graphics controller supports a single frame buffer. If a graphics device supports multiple frame buffers, then handles for the frame buffers must be created first, and then the handles for the video output devices can be created as children of the frame buffer handles.

Summary of Initialization Steps:

- “If *RemainingDevicePath* is *NULL* or the first Device Path Node is the End of Device Path Node, then *Supported()* returns *EFI_SUCCESS* . Otherwise, if the first node of *RemainingDevicePath* is not an ACPI _ADR node or the first two nodes of *RemainingDevicePath* are not a Controller node followed by an ACPI _ADR node, then *Supported()* returns *EFI_UNSUPPORTED* .
- “If *Supported()* returned *EFI_SUCCESS* , system calls *Start()* .
- “If *RemainingDevicePath* is *NULL* , then a default set of active video output devices are selected by the driver.
- “If the first Device Path Node of *RemainingDevicePath* is the End of Device Path Node, then skip to the “The EFI Driver must provide *EFI_COMPONENT_NAME2_PROTOCOL* ” step.
- Start() function creates a ChildHandle for each physical video output device and installs the EFI_DEVICE_PATH_PROTOCOL onto the created ChildHandle. The EFI_DEVICE_PATH_PROTOCOL is constructed by appending an ACPI _ADR device path node describing the physical video output device to the end of the device path installed on the ControllerHandle passed into Start().
- Start()function retrieves EDID information for each physical video output device and installs the EFI_EDID_DISCOVERED_PROTOCOL onto the ChildHandle for each physical video output device. If no EDID data is available from the video output device, then SizeOfEdid is set to zero, and Edid is set to NULL.
- Start()function create a ChildHandle for each valid combination of two or more video output devices, and installs the EFI_DEVICE_PATH_PROTOCOL onto the created ChildHandle. The EFI_DEVICE_PATH_PROTOCOL is constructed by appending an ACPI _ADR device path node describing the combination of video output devices to the end of the device path installed on the ControllerHandle passed into Start(). The ACPI _ADR entry can represent complex topologies of devices and it is possible to have more than one ACPI _ADR entry in a single device path node. Support of complex video output device topologies is an optional feature.
- Start()function evaluates the RemainingDevicePath to select the set of active video output devices. If RemainingDevicePath is NULL, then Start() selects a default set of video output devices. If RemainingDevicePath is not NULL, and ACPI _ADR device path node of RemainingDevicePath does not match any of the created ChildHandles, then Start()must destroy all its ChildHandles and return EFI_UNSUPPORTED. Otherwise, Start() selects the set of active video output devices specified by the ACPI _ADR device path node in RemainingDevicePath.
- Start() retrieves the ChildHandle associated with each active video output device. Only ChildHandles that represent a physical video output device are considered. Start() calls the EFI_EDID_OVERRIDE_PROTOCOL.GetEdid() service passing in ChildHandle. Depending on the return values from GetEdid(), either the override EDID information or the EDID information from the EFI_EDID_DISCOVERED_PROTOCOL on ChildHandle is selected. See GetEdid() for a detailed description of this decision. The selected EDID information is used to produce the EFI_EDID_ACTIVE_PROTOCOL, and that protocol is installed onto ChildHandle.

- Start() retrieves the one ChildHandle that represents the entire set of active video output devices. If this set is a single video output device, then this ChildHandle will be the same as the one used in the previous step. If this set is a combination of video output devices, then this will not be one of the ChildHandles used in the previous two steps. The EFI_GRAPHICS_OUTPUT_PROTOCOL is installed onto this ChildHandle.
- The QueryMode() service of the EFI_GRAPHICS_OUTPUT_PROTOCOL returns the set of modes that both the graphics controller and the set of active video output devices all support. If a different set of active video output device is selected, then a different set of modes will likely be produced by QueryMode().
- Start()function optionally initializes video frame buffer hardware. The EFI driver has the option of delaying this operation until SetMode() is called.
- The EFI Driver must provide EFI_COMPONENT_NAME2_PROTOCOL GetControllerName() support for ControllerHandle and all the ChildHandles created by this driver. The name returned for ControllerHandle must return the name of the graphics device. The name returned for each of the ChildHandles allow the user to pick output display settings and should be constructed with this in mind.
- The EFI Driver's Stop() function must cleanly undo what the Start() function created.
- An EFI_GRAPHICS_OUTPUT_PROTOCOL must be implemented for every video frame buffer that exists on a video adapter. In most cases there will be a single EFI_GRAPHICS_OUTPUT_PROTOCOL placed on one of the a children of the ControllerHandle passed into the EFI_DRIVER_BINDING.Start() function.

If a single PCI device/function contains multiple frame buffers the EFI_GRAPHICS_OUTPUT_PROTOCOL must create child handles of the PCI handle that inherit its PCI device path and appends a controller device path node. The handles for the video output devices are children of the handles that represent the frame buffers.

A video device can support an arbitrary number of geometries, but it must support one or more of the following modes to conform to this specification:

Onboard graphics device

- A mode required in a platform design guide
- Native mode of the display

Plug in graphics device

- A mode required in a platform design guide
- 800 x 600 with 32-bit color depth or 640 x 480 with 32-bit color depth and a pixel format described by PixelRedGreenBlueReserved8BitPerColor or PixelBlueGreenRedReserved8BitPerColor.

If graphics output device supports both landscape and portrait mode displays it must return a different mode via QueryMode(). For example landscape mode could be 800 horizontal and 600 vertical while the equivalent portrait mode would be 600 horizontal and 800 vertical.

CHAPTER

THIRTEEN

PROTOCOLS – MEDIA ACCESS

13.1 Load File Protocol

The Load File protocol is used to obtain files, that are primarily boot options, from arbitrary devices.

13.1.1 EFI_LOAD_FILE_PROTOCOL

Summary

Used to obtain files, that are primarily boot options, from arbitrary devices.

GUID

```
#define EFI_LOAD_FILE_PROTOCOL_GUID \
 {0x56EC3091,0x954C,0x11d2,\
  {0x8e,0x3f,0x00,0xa0, 0xc9,0x69,0x72,0x3b}}
```

Protocol Interface Structure

```
typedef struct  _EFI_LOAD_FILE_PROTOCOL {
   EFI_LOAD_FILE                       LoadFile;
} EFI_LOAD_FILE_PROTOCOL;
```

Parameters

LoadFile
Causes the driver to load the requested file. See the *EFI_LOAD_FILE_PROTOCOL.LoadFile()* function description.

Description

The EFI_LOAD_FILE_PROTOCOL is a simple protocol used to obtain files from arbitrary devices.

When the firmware is attempting to load a file, it first attempts to use the device's Simple File System protocol to read the file. If the file system protocol is found, the firmware implements the policy of interpreting the File Path value of the file being loaded. If the device does not support the file system protocol, the firmware then attempts to read the file via the EFI_LOAD_FILE_PROTOCOL and the LoadFile() function. In this case the LoadFile() function implements the policy of interpreting the File Path value.

13.1.2 EFI_LOAD_FILE_PROTOCOL.LoadFile()

Summary

Causes the driver to load a specified file.

Prototype

```
typedef
EFI_STATUS
 (EFIAPI *EFI_LOAD_FILE) (
 IN EFI_LOAD_FILE_PROTOCOL                 *This,
 IN EFI_DEVICE_PATH_PROTOCOL               *FilePath,
 IN BOOLEAN                                BootPolicy,
 IN OUT UINTN                              *BufferSize,
 IN VOID                                   *Buffer OPTIONAL
 );
```

Parameters

This

Indicates a pointer to the calling context. Type *EFI_LOAD_FILE_PROTOCOL* is defined in *Load File Protocol*.

FilePath

The device specific path of the file to load. Type EFI_DEVICE_PATH_PROTOCOL is defined in *EFI Device Path Protocol* .

BootPolicy

If **TRUE**, indicates that the request originates from the boot manager, and that the boot manager is attempting to load FilePath as a boot selection. If **FALSE**, then FilePath must match an exact file to be loaded.

BufferSize

On input the size of Buffer in bytes. On output with a return code of EFI_SUCCESS, the amount of data transferred to Buffer. On output with a return code of EFI_BUFFER_TOO_SMALL, the size of Buffer required to retrieve the requested file.

Buffer

The memory buffer to transfer the file to. If Buffer is NULL, then the size of the requested file is returned in BufferSize.

Description

The LoadFile() function interprets the device-specific FilePath parameter, returns the entire file into Buffer, and sets BufferSize to the amount of data returned. If Buffer is **NULL**, then the size of the file is returned in BufferSize. If Buffer is not **NULL**, and BufferSize is not large enough to hold the entire file, then EFI_BUFFER_TOO_SMALL is returned, and BufferSize is updated to indicate the size of the buffer needed to obtain the file. In this case, no data is returned in Buffer.

If BootPolicy is **FALSE** the FilePath must match an exact file to be loaded. If no such file exists, EFI_NOT_FOUND is returned. If BootPolicy is **FALSE**, and an attempt is being made to perform a network boot through the PXE Base Code protocol, EFI_UNSUPPORTED is returned.

If BootPolicy is **TRUE** the firmware's boot manager is attempting to load an EFI image that is a boot selection. In this case, FilePath contains the file path value in the boot selection option. Normally the firmware would implement the policy on how to handle an inexact boot file path; however, since in this case the firmware cannot interpret the file path, the LoadFile() function is responsible for implementing the policy. For example, in the case of a network boot through the PXE Base Code protocol, FilePath merely points to the root of the device, and the firmware interprets this as wanting to boot from the first valid loader. The following is a list of events that LoadFile() will implement for a PXE boot:

- Perform DHCP.
- Optionally prompt the user with a menu of boot selections.
- Discover the boot server and the boot file.
- Download the boot file into Buffer and update BufferSize with the size of the boot file.

If the boot file downloaded from boot server is not an UEFI-formatted executable, but a binary image which contains a UEFI-compliant file system, then *EFI_WARN_FILE_SYSTEM* is returned, and a new RAM disk mapped on the returned *Buffer* is registered.

Status Codes Returned

EFI_SUCCESS	The file was loaded.
EFI_UNSUPPORTED	The device does not support the provided BootPolicy.
EFI_INVALID_PARAMETER	FilePath is not a valid device path, or BufferSize is NULL.
EFI_NO_MEDIA	No medium was present to load the file.
EFI_DEVICE_ERROR	The file was not loaded due to a device error.
EFI_NO_RESPONSE	The remote system did not respond.
EFI_NOT_FOUND	The file was not found.
EFI_ABORTED	The file load process was manually cancelled.
EFI_BUFFER_TOO_SMALL	The *BufferSize* is too small to read the current directory entry. *BufferSize* has been updated with the size needed to complete the request.
EFI_WARN_FILE_SYSTEM	The resulting *Buffer* contains UEFI-compliant file system.

13.2 Load File 2 Protocol

The Load File 2 protocol is used to obtain files from arbitrary devices that are not boot options.

13.2.1 EFI_LOAD_FILE2_PROTOCOL

Summary

Used to obtain files from arbitrary devices but are not used as boot options.

GUID

```
#define EFI_LOAD_FILE2_PROTOCOL_GUID \
 { 0x4006c0c1, 0xfcb3, 0x403e, \
 { 0x99, 0x6d, 0x4a, 0x6c, 0x87, 0x24, 0xe0, 0x6d }}
```

Protocol Interface Structure

```
typedef EFI_LOAD_FILE_PROTOCOL EFI_LOAD_FILE2_PROTOCOL;
```

Parameters

LoadFile
Causes the driver to load the requested file. See the *LoadFile()* functional description.

Description

The *EFI_LOAD_FILE2_PROTOCOL* is a simple protocol used to obtain files from arbitrary devices that are not boot options. It is used by *LoadImage()* when its *BootOption* parameter is *FALSE* and the *FilePath* does not have an instance of the *EFI_SIMPLE_FILE_SYSTEM_PROTOCOL*.

13.2.2 EFI_LOAD_FILE2_PROTOCOL.LoadFile()

Summary

Causes the driver to load a specified file.

Prototype

The same prototype as *EFI_LOAD_FILE_PROTOCOL.LoadFile()*.

Parameters

This
Indicates a pointer to the calling context.

FilePath
The device specific path of the file to load.

BootPolicy
Should always be *FALSE*.

BufferSize
On input the size of *Buffer* in bytes. On output with a return code of *EFI_SUCCESS,* the amount of data transferred to *Buffer*. On output with a return code of *EFI_BUFFER_TOO_SMALL,* the size of *Buffer* required to retrieve the requested file.

Buffer
The memory buffer to transfer the file to. If *Buffer* is *NULL,* then no the size of the requested file is returned in *BufferSize*.

Description

The *LoadFile()* function interprets the device-specific *FilePath* parameter, returns the entire file into *Buffer,* and sets *BufferSize* to the amount of data returned. If *Buffer* is **NULL,** then the size of the file is returned in *BufferSize*. If *Buffer* is not **NULL,** and *BufferSize* is not large enough to hold the entire file, then *EFI_BUFFER_TOO_SMALL* is returned, and *BufferSize* is updated to indicate the size of the buffer needed to obtain the file. In this case, no data is returned in *Buffer*.

FilePath contains the file path value in the boot selection option. Normally the firmware would implement the policy on how to handle an inexact boot file path; however, since in this case the firmware cannot interpret the file path, the *LoadFile()* function is responsible for implementing the policy.

Status Codes Returned

EFI_SUCCESS	The file was loaded.
EFI_UNSUPPORTED	BootPolicy is **TRUE**.
EFI_INVALID_PARAMETER	FilePath is not a valid device path, or BufferSize is NULL.
EFI_NO_MEDIA	No medium was present to load the file.
EFI_DEVICE_ERROR	The file was not loaded due to a device error.
EFI_NO_RESPONSE	The remote system did not respond.
EFI_NOT_FOUND	The file was not found.
EFI_ABORTED	The file load process was manually cancelled.
EFI_BUFFER_TOO_SMALL	The BufferSize is too small to read the current directory entry. BufferSize has been updated with the size needed to complete the request.

13.3 File System Format

The file system supported by the Extensible Firmware Interface is based on the FAT file system. EFI defines a specific version of FAT that is explicitly documented and testable. Conformance to the EFI specification and its associate reference documents is the only definition of FAT that needs to be implemented to support EFI. To differentiate the EFI file system from pure FAT, a new partition file system type has been defined.

EFI encompasses the use of FAT32 for a system partition, and FAT12 or FAT16 for removable media. The FAT32 system partition is identified by an OSType value other than that used to identify previous versions of FAT. This unique partition type distinguishes an EFI defined file system from a normal FAT file system. The file system supported by EFI includes support for long file names.

The definition of the EFI file system will be maintained by specification and will not evolve over time to deal with errata or variant interpretations in OS file system drivers or file system utilities. Future enhancements and compatibility enhancements to FAT will not be automatically included in EFI file systems. The EFI file system is a target that is fixed by the EFI specification, and other specifications explicitly referenced by the EFI specification.

For more information about the EFI file system and file image format, visit the web site from which this document was obtained.

13.3.1 System Partition

A System Partition is a partition in the conventional sense of a partition on a legacy system. For a hard disk, a partition is a contiguous grouping of sectors on the disk where the starting sector and size are defined by the Master Boot Record (MBR), which resides on LBA 0 (i.e., the first sector of the hard disk) (*LBA 0 Format*), or the GUID Partition Table (GPT), which resides on logical block 1 (the second sector of the hard disk) (*GPT overview*). For a diskette (floppy) drive, a partition is defined to be the entire media. A System Partition can reside on any media that is supported by EFI Boot Services.

A System Partition supports backward compatibility with legacy systems by reserving the first block (sector) of the partition for compatibility code. On legacy systems, the first block (sector) of a partition is loaded into memory and execution is transferred to this code. EFI firmware does not execute the code in the MBR. The EFI firmware contains knowledge about the partition structure of various devices, and can understand legacy MBR, GPT, and “El Torito.”

The System Partition contains directories, data files, and UEFI Images. UEFI Images can contain a OS Loader, an driver to extend platform firmware capability, or an application that provides a transient service to the system. Applications written to this specification could include things such as a utility to create partitions or extended diagnostics. A System Partition can also support data files, such as error logs, that can be defined and used by various OS or system firmware software components.

13.3.1.1 File System Format

The first block (sector) of a partition contains a data structure called the BIOS Parameter Block (BPB) that defines the type and location of FAT file system on the drive. The BPB contains a data structure that defines the size of the media, the size of reserved space, the number of FAT tables, and the location and size of the root directory (not used in FAT32). The first block (sector) also contains code that will be executed as part of the boot process on a legacy system. This code in the first block (sector) usually contains code that can read a file from the root directory into memory and transfer control to it. Since EFI firmware contains a file system driver, EFI firmware can load any file from the file system with out nhe FAT32, FAT16, and FAT12 variants of the EFI file system. What variant of EFI FAT to use is defined by the size of the media. The rules defining theeeding to execute any code from the media.

The EFI firmware must support the FAT32, FAT16, and FAT12 variants of the EFI file system. What variant of EFI FAT to use is defined by the size of the media. The rules defining the relationship between media size and FAT variants is defined in the specification for the EFI file system.

The UEFI system partition FAT32 Data region should be aligned to the physical block boundary and optimal transfer length granularity of the device (*GPT overview*). This is controlled by the BPB_RsvdSecCnt field and the applicable BPB_FATSz field (e.g., formatting software may set the BPB_RsvdSecCnt field to a value that results in alignment and/or may set the BPB_FATSz field to a value that ensures alignment).

13.3.1.2 File Names

FAT stores file names in two formats. The original FAT format limited file names to eight characters with three extension characters. This type of file name is called an 8.3, pronounced eight dot three, file name. FAT was extended to include support for long file names (LFN).

FAT 8.3 file names are always stored as uppercase ASCII characters. LFN can either be stored as ASCII or UCS-2 characters and are stored case sensitive. The string that was used to open or create the file is stored directly into LFN. FAT defines that all files in a directory must have a unique name, and unique is defined as a case insensitive match. The following are examples of names that are considered to be the same and cannot exist in a single directory:

- “ThisIsAnExampleDirectory.Dir”
- “thisisanexamppledirectory.dir”
- THISISANEXAMPLEDIRECTORY.DIR
- ThisIsAnExampleDirectory.DIR

Note: *Although the FAT32 specification allows file names to be encoded using UTF-16, this specification only recognizes the UCS-2 subset for the purposes of sorting or collation.*

13.3.1.3 Directory Structure

An EFI system partition that is present on a hard disk must contain an EFI defined directory in the root directory. This directory is named EFI. All OS loaders and applications will be stored in subdirectories below EFI. Applications that are loaded by other applications or drivers are not required to be stored in any specific location in the EFI system partition. The choice of the subdirectory name is up to the vendor, but all vendors must pick names that do not collide with any other vendor’s subdirectory name. This applies to system manufacturers, operating system vendors, BIOS vendors, and third party tool vendors, or any other vendor that wishes to install files on an EFI system partition. There must also only be one executable EFI image for each supported processor architecture in each vendor subdirectory. This guarantees that there is only one image that can be loaded from a vendor subdirectory by the EFI Boot Manager. If more than one executable EFI image is present, then the boot behavior for the system will not be deterministic. There may also be an optional vendor subdirectory called BOOT.

This directory contains EFI images that aide in recovery if the boot selections for the software installed on the EFI system partition are ever lost. Any additional UEFI-compliant executables must be in subdirectories below the vendor subdirectory. The following is a sample directory structure for an EFI system partition present on a hard disk.

```
\EFI
   \<OS Vendor 1 Directory>
         <OS Loader Image>
   \<OS Vendor 2 Directory>
         <OS Loader Image>
  ...

   \<OS Vendor N Directory>
```

(continues on next page)

(continued from previous page)

```
        <OS Loader Image>
   \<OEM Directory>
        <OEM Application Image>
   \<BIOS Vendor Directory>
        <BIOS Vendor Application Image>
   \<Third Party Tool Vendor Directory>
        <Third Party Tool Vendor Application Image>
   \BOOT
        BOOT{machine type short name}.EFI
```

For removable media devices there must be only one UEFI-compliant system partition, and that partition must contain an UEFI-defined directory in the root directory. The directory will be named EFI. All OS loaders and applications will be stored in a subdirectory below EFI called BOOT. There must only be one executable EFI image for each supported processor architecture in the BOOT directory. For removable media to be bootable under EFI, it must be built in accordance with the rules laid out in *Removable Media Boot Behavior*. This guarantees that there is only one image that can be automatically loaded from a removable media device by the EFI Boot Manager. Any additional EFI executables must be in directories other than BOOT. The following is a sample directory structure for an EFI system partition present on a removable media device.

```
\EFI
   \BOOT
   BOOT{machine type short name}.EFI
```

13.3.2 Partition Discovery

This specification requires the firmware to be able to parse the *Legacy MBR*), GUID Partition Table (GPT)(*GPT overview*), and El Torito (*ISO-9660 and El Torito*) logical device volumes. The EFI firmware produces a logical *EFI_BLOCK_IO_PROTOCOL* device for:

- each GUID Partition Entry (see table 16 in 5.3.3) with bit 1 set to zero;
- each El Torito logical device volume; and
- if no GPT is present, each partition found in the legacy MBR partition tables.

LBA zero of the *EFI_BLOCK_IO_PROTOCOL* device will correspond to the first logical block of the partition. See *Nesting of Legacy MBR Partition Records*. If a GPT Partition Entry has Attribute bit 1 set then a logical *EFI_BLOCK_IO_PROTOCOL* device must not be created.

The following is the order in which a block device must be scanned to determine if it contains partitions. When a check for a valid partitioning scheme succeeds, the search terminates.

1. Check for GUID Partition Table Headers.
2. Follow ISO-9660 specification to search for ISO-9660 volume structures on the magic LBA.
3. Check for an “El Torito” volume extension and follow the “El Torito” CD-ROM specification.
4. If none of the above, check LBA 0 for a legacy MBR partition table.
5. No partition found on device.

If a disk contains a recognized RAID structure (e.g. DDF structure as defined in *The Storage Networking Industry Association Common RAID Disk Data Format Specification*– see Glossary), the data on the disk must be ignored, unless the driver is using the RAID structure to produce a logical RAID volume.

EFI supports the nesting of legacy MBR partitions, by allowing any legacy MBR partition to contain more legacy MBR partitions. This is accomplished by supporting the same partition discovery algorithm on every logical block device. It

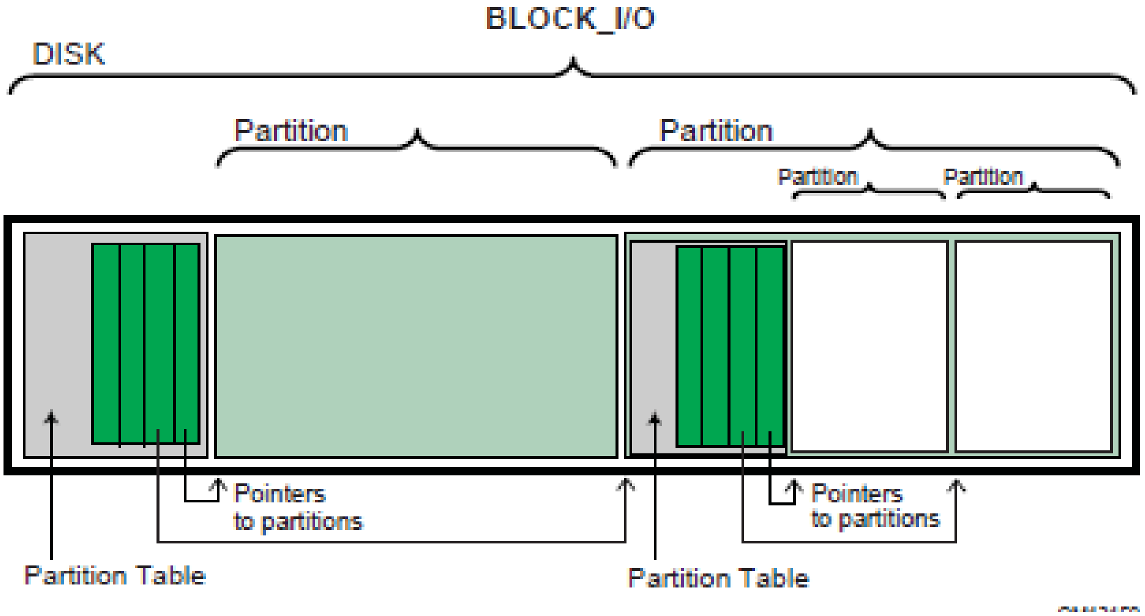

Fig. 13.1: Nesting of Legacy MBR Partition Records

should be noted that the GUID Partition Table does not allow nesting of GUID Partition Table Headers. Nesting is not needed since a GUID Partition Table Header can support an arbitrary number of partitions (the addressability limits of a 64-bit LBA are the limiting factor).

13.3.2.1 ISO-9660 and El Torito

IS0-9660 is the industry standard low level format used on CD-ROM and DVD-ROM. The CD-ROM format is completely described by the "El Torito" Bootable CD-ROM Format Specification Version 1.0. To boot from a CD-ROM or DVD-ROM in the boot services environment, an EFI System partition is stored in a "no emulation" mode as defined by the "El Torito" specification. A Platform ID of 0xEF indicates an EFI System Partition. The Platform ID is in either the Section Header Entry or the Validation Entry of the Booting Catalog as defined by the "El Torito" specification. EFI differs from "El Torito" "no emulation" mode in that it does not load the "no emulation" image into memory and jump to it. EFI interprets the "no emulation" image as an EFI system partition. EFI interprets the Sector Count in the Initial/Default Entry or the Section Header Entry to be the size of the EFI system partition. If the value of Sector Count is set to 0 or 1, EFI will assume the system partition consumes the space from the beginning of the "no emulation" image to the end of the CD-ROM.

A DVD-ROM image formatted as required by the UDF 2.0 specification (OSTA Universal Disk Format Specification, Revision 2.0) shall be booted by UEFI if:

- the DVD-ROM image conforms to the "UDF Bridge" format defined in the UDF 2.0 specification, and
- the DVD-ROM image contains exactly one ISO-9660 file system, and
- the ISO-9660 file system conforms to the "El Torito" Bootable CD-ROM Format Specification.

Booting from a DVD-ROM that satisfies the above requirements is accomplished using the same methods as booting from a CD-ROM: the ISO-9660 file system shall be booted.

Since the EFI file system definition does not use the same Initial/Default entry as a legacy CD-ROM it is possible to boot personal computers using an EFI CD-ROM or DVD-ROM. The inclusion of boot code for personal computers is optional and not required by EFI.

13.3.3 Number and Location of System Partitions

UEFI does not impose a restriction on the number or location of System Partitions that can exist on a system. System Partitions are discovered when required by UEFI firmware by examining the partition GUID and verifying that the contents of the partition conform to the FAT file system as defined in *File System Format*. Further, UEFI implementations may allow the use of conforming FAT partitions which do not use the ESP GUID. Partition creators may prevent UEFI firmware from examining and using a specific partition by setting bit 1 of the Partition Attributes (see 5.3.3) which will exclude the partition as a potential ESP.

Software installation may choose to create and locate an ESP on each target OS boot disk, or may choose to create a single ESP independent of the location of OS boot disks and OS partitions. It is outside of the scope of this specification to attempt to coordinate the specification of size and location of an ESP that can be shared by multiple OS or Diagnostics installations, or to manage potential namespace collisions in directory naming in a single (central) ESP.

13.3.4 Media Formats

This section describes how booting from different types of removable media is handled. In general the rules are consistent regardless of a media's physical type and whether it is removable or not.

13.3.4.1 Removable Media

Removable media may contain a standard FAT12, FAT16, or FAT32 file system.

Booting from a removable media device can be accomplished the same way as any other boot. The boot file path provided to the boot manager can consist of a UEFI application image to load, or can merely be the path to a removable media device. In the first case, the path clearly indicates the image that is to be loaded. In the later case, the boot manager implements the policy to load the default application image from the device.

For removable media to be bootable under EFI, it must be built in accordance with the rules laid out in *Removable Media Boot Behavior*

13.3.4.2 Diskette

EFI bootable diskettes follow the standard formatting conventions used on personal computers. The diskette contains only a single partition that complies to the EFI file system type. For diskettes to be bootable under EFI, it must be built in accordance with the rules laid out in *Removable Media Boot Behavior*.

Since the EFI file system definition does not use the code in the first block of the diskette, it is possible to boot personal computers using a diskette that is also formatted as an EFI bootable removable media device. The inclusion of boot code for personal computers is optional and not required by EFI.

Diskettes include the legacy 3.5-inch diskette drives as well as the newer larger capacity removable media drives such as an Iomega* Zip,* Fujitsu MO, or MKE LS-120/SuperDisk*.

13.3.4.3 Hard Drive

Hard drives may contain multiple partitions as defined in See *Partition Discovery* on partition discovery. Any partition on the hard drive may contain a file system that the EFI firmware recognizes. Images that are to be booted must be stored under the EFI subdirectory as defined in *System Partition* and *Partition Discovery*.

EFI code does not assume a fixed block size.

Since EFI firmware does not execute the MBR code and does not depend on the BootIndicator field in the legacy MBR partition records, the hard disk can still boot and function normally.

13.3.4.4 CD-ROM and DVD-ROM

A CD-ROM or DVD-ROM may contain multiple partitions as defined in *System Partition* and *Partition Discovery* and in the "El Torito" specification.

EFI code does not assume a fixed block size.

Since the EFI file system definition does not use the same Initial/Default entry as a legacy CD-ROM, it is possible to boot personal computers using an EFI CD-ROM or DVD-ROM. The inclusion of boot code for personal computers is optional and not required by EFI.

13.3.4.5 Network

To boot from a network device, the Boot Manager uses the Load File Protocol to perform a *EFI_LOAD_FILE_PROTOCOL.LoadFile()* on the network device. This uses the PXE Base Code Protocol to perform DHCP and Discovery. This may result in a list of possible boot servers along with the boot files available on each server. The Load File Protocol for a network boot may then optionally produce a menu of these selections for the user to choose from. If this menu is presented, it will always have a timeout, so the Load File Protocol can automatically boot the default boot selection. If there is only one possible boot file, then the Load File Protocol can automatically attempt to load the one boot file.

The Load File Protocol will download the boot file using the MTFTP service in the PXE Base Code Protocol. The downloaded image must be an EFI image that the platform supports.

13.4 Simple File System Protocol

The Simple File System protocol allows code running in the EFI boot services environment to obtain file based access to a device. *EFI_SIMPLE_FILE_SYSTEM_PROTOCOL* is used to open a device volume and return an *EFI_FILE_PROTOCOL* that provides interfaces to access files on a device volume.

13.4.1 EFI_SIMPLE_FILE_SYSTEM_PROTOCOL

Summary

Provides a minimal interface for file-type access to a device.

GUID

```
#define EFI_SIMPLE_FILE_SYSTEM_PROTOCOL_GUID \
 {0x0964e5b22,0x6459,0x11d2,\
  {0x8e,0x39,0x00,0xa0,0xc9,0x69,0x72,0x3b}}
```

Revision Number

```
#define EFI_SIMPLE_FILE_SYSTEM_PROTOCOL_REVISION 0x00010000
```

Protocol Interface Structure

```
typedef struct _EFI_SIMPLE_FILE_SYSTEM_PROTOCOL {
 UINT64                                         Revision;
 EFI_SIMPLE_FILE_SYSTEM_PROTOCOL_OPEN_VOLUME    OpenVolume;
} EFI_SIMPLE_FILE_SYSTEM_PROTOCOL;
```

Parameters

Revision
The version of the EFI_FILE_PROTOCOL. The version specified by this specification is 0x00010000. All future revisions must be backwards compatible. If a future version is not backwards compatible, it is not the same GUID.

OpenVolume
Opens the volume for file I/O access. See the OpenVolume() *EFI_SIMPLE_FILE SYSTEM_PROTOCOL.OpenVolume()* function description.

Description

The EFI_SIMPLE_FILE_SYSTEM_PROTOCOL provides a minimal interface for file-type access to a device. This protocol is only supported on some devices.

Devices that support the Simple File System protocol return an EFI_FILE_PROTOCOL. The only function of this interface is to open a handle to the root directory of the file system on the volume. Once opened, all accesses to the volume are performed through the volume's file handles, using the *EFI_FILE_PROTOCOL* protocol. The volume is closed by closing all the open file handles.

The firmware automatically creates handles for any block device that supports the following file system formats:

- FAT12
- FAT16
- FAT32

13.4.2 EFI_SIMPLE_FILE SYSTEM_PROTOCOL.OpenVolume()

Summary

Opens the root directory on a volume.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SIMPLE_FILE_SYSTEM_PROTOCOL_OPEN_VOLUME) (
  IN EFI_SIMPLE_FILE_SYSTEM PROTOCOL                   *This,
  OUT EFI_FILE_PROTOCOL                                **Root
  );
```

Parameters

This
A pointer to the volume to open the root directory of. See the type *EFI_SIMPLE_FILE_SYSTEM_PROTOCOL* description.

Root

A pointer to the location to return the opened file handle for the root directory. See the type see *EFI_FILE_PROTOCOL* description.

Description

The OpenVolume() function opens a volume, and returns a file handle to the volume's root directory. This handle is used to perform all other file I/O operations. The volume remains open until all the file handles to it are closed.

If the medium is changed while there are open file handles to the volume, all file handles to the volume will return EFI_MEDIA_CHANGED. To access the files on the new medium, the volume must be reopened with OpenVolume(). If the new medium is a different file system than the one supplied in the EFI_HANDLE's DevicePath for the EFI_SIMPLE_SYSTEM_PROTOCOL, OpenVolume() will return EFI_UNSUPPORTED.

Status Codes Returned

EFI_SUCCESS	The file volume was opened.
EFI_UNSUPPORTED	The volume does not support the requested file system type.
EFI_NO_MEDIA	The device has no medium.
EFI_DEVICE_ERROR	The device reported an error.
EFI_VOLUME_CORRUPTED	The file system structures are corrupted.
EFI_ACCESS_DENIED	The service denied access to the file.
EFI_OUT_OF_RESOURCES	The file volume was not opened.
EFI_MEDIA_CHANGED	The device has a different medium in it or the medium is no longer supported. Any existing file handles for this volume are no longer valid. To access the files on the new medium, the volume must be reopened with OpenVolume().

13.5 File Protocol

The protocol and functions described in this section support access to EFI-supported file systems.

13.5.1 EFI_FILE_PROTOCOL

Summary

Provides file based access to supported file systems.

Revision Number

```
#define EFI_FILE_PROTOCOL_REVISION           0x00010000
#define EFI_FILE_PROTOCOL_REVISION2          0x00020000
#define EFI_FILE_PROTOCOL_LATEST_REVISION EFI_FILE_PROTOCOL_REVISION2
```

Protocol Interface Structure

```
typedef struct_EFI_FILE_PROTOCOL {
  UINT64                          Revision;
  EFI_FILE_OPEN                   Open;
  EFI_FILE_CLOSE                  Close;
  EFI_FILE_DELETE                 Delete;
  EFI_FILE_READ                   Read;
  EFI_FILE_WRITE                  Write;
  EFI_FILE_GET_POSITION           GetPosition;
```

(continues on next page)

(continued from previous page)

```
  EFI_FILE_SET_POSITION           SetPosition;
  EFI_FILE_GET_INFO               GetInfo;
  EFI_FILE_SET_INFO               SetInfo;
  EFI_FILE_FLUSH                  Flush;
  EFI_FILE_OPEN_EX                OpenEx; // Added for revision 2
  EFI_FILE_READ_EX                ReadEx; // Added for revision 2
  EFI_FILE_WRITE_EX               WriteEx; // Added for revision 2
  EFI_FILE_FLUSH_EX               FlushEx; // Added for revision 2
} EFI_FILE_PROTOCOL;
```

Parameters

Revision
The version of the EFI_FILE_PROTOCOL interface. The version specified by this specification is *EFI_FILE_PROTOCOL_LATEST_REVISION*. Future versions are required to be backward compatible to version 1.0.

Open
Opens or creates a new file. See the *EFI_FILE_PROTOCOL.Open()* function description.

Close
Closes the current file handle. See the *EFI_FILE_PROTOCOL.Close()* function description.

Delete
Deletes a file. See the *EFI_FILE_PROTOCOL.Delete()* function description.

Read
Reads bytes from a file. See the *EFI_FILE_PROTOCOL.Read()* function description.

Write
Writes bytes to a file. See the *EFI_FILE_PROTOCOL.Write()* function description.

GetPosition
Returns the current file position. See the *EFI_FILE_PROTOCOL.GetPosition()* function description.

SetPosition
Sets the current file position. See the *EFI_FILE_PROTOCOL.SetPosition()* function description.

GetInfo
Gets the requested file or volume information. See the *EFI_FILE_PROTOCOL.GetInfo()* function description.

SetInfo
Sets the requested file information. See the *EFI_FILE_PROTOCOL.SetInfo()* function description.

Flush
Flushes all modified data associated with the file to the device. See the *EFI_FILE_PROTOCOL.Flush()* function description.

OpenEx
Opens a new file relative to the source directory's location.

ReadEx
Reads data from a file.

WriteEx
Writes data to a file.

FlushEx
Flushes all modified data associated with a file to a device.

Description

The EFI_FILE_PROTOCOL provides file IO access to supported file systems.

An EFI_FILE_PROTOCOL provides access to a file's or directory's contents, and is also a reference to a location in the directory tree of the file system in which the file resides. With any given file handle, other files may be opened relative to this file's location, yielding new file handles.

On requesting the file system protocol on a device, the caller gets the *EFI_FILE_PROTOCOL* to the volume. This interface is used to open the root directory of the file system when needed. The caller must *EFI_FILE_PROTOCOL.Close()* the file handle to the root directory, and any other opened file handles before exiting. While there are open files on the device, usage of underlying device protocol(s) that the file system is abstracting must be avoided. For example, when a file system that is layered on a *EFI_DISK_IO_PROTOCOL EFI_BLOCK_IO_PROTOCOL* , direct block access to the device for the blocks that comprise the file system must be avoided while there are open file handles to the same device.

A file system driver may cache data relating to an open file. A Flush() function is provided that flushes all dirty data in the file system, relative to the requested file, to the physical medium. If the underlying device may cache data, the file system must inform the device to flush as well.

Implementations must account for cases where there is pending queued asynchronous I/O when a call is received on a blocking protocol interface. In these cases the pending I/O will be processed and completed before the blocking function is executed so that operation are carried out in the order they were requested.

13.5.2 EFI_FILE_PROTOCOL.Open()

Summary

Opens a new file relative to the source file's location.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_FILE_OPEN) (
  IN EFI_FILE_PROTOCOL                  *This,
  OUT EFI_FILE_PROTOCOL                 **NewHandle,
  IN CHAR16                             *FileName,
  IN UINT64                             OpenMode,
  IN UINT64                             Attributes
  );
```

Parameters

This
A pointer to the *EFI_FILE_PROTOCOL* instance that is the file handle to the source location. This would typically be an open handle to a directory. See the type EFI_FILE_PROTOCOL description.

NewHandle
A pointer to the location to return the opened handle for the new file. See the type EFI_FILE_PROTOCOL description.

FileName
The Null-terminated string of the name of the file to be opened. The file name may contain the following path modifiers: “", “.”, and “..”.

OpenMode
The mode to open the file. The only valid combinations that the file may be opened with are: Read, Read/Write, or Create/Read/Write. See “Related Definitions” below.

Attributes

Only valid for EFI_FILE_MODE_CREATE, in which case these are the attribute bits for the newly created file. See "Related Definitions" below.

Related Definitions

```
//*******************************************************
// Open Modes
//*******************************************************
#define EFI_FILE_MODE_READ       0x0000000000000001
#define EFI_FILE_MODE_WRITE      0x0000000000000002
#define EFI_FILE_MODE_CREATE     0x8000000000000000

//*******************************************************
// File Attributes
//*******************************************************
#define EFI_FILE_READ_ONLY       0x0000000000000001
#define EFI_FILE_HIDDEN          0x0000000000000002
#define EFI_FILE_SYSTEM          0x0000000000000004
#define EFI_FILE_RESERVED        0x0000000000000008
#define EFI_FILE_DIRECTORY       0x0000000000000010
#define EFI_FILE_ARCHIVE         0x0000000000000020
#define EFI_FILE_VALID_ATTR      0x0000000000000037
```

Description

The Open()function opens the file or directory referred to by FileName relative to the location of This and returns a NewHandle. The FileName may include the following path modifiers:

"\"

If the filename starts with a "\" the relative location is the root directory that This resides on; otherwise "" separates name components. Each name component is opened in turn, and the handle to the last file opened is returned.

"."

Opens the current location.

".."

Opens the parent directory for the current location. If the location is the root directory the request will return an error, as there is no parent directory for the root directory.

If EFI_FILE_MODE_CREATE is set, then the file is created in the directory. If the final location of FileName does not refer to a directory, then the operation fails. If the file does not exist in the directory, then a new file is created. If the file already exists in the directory, then the existing file is opened.

If the medium of the device changes, all accesses (including the File handle) will result in EFI_MEDIA_CHANGED. To access the new medium, the volume must be reopened.

Status Codes Returned

EFI_SUCCESS	The file was opened.
EFI_NOT_FOUND	The specified file could not be found on the device.
EFI_NO_MEDIA	The device has no medium.
EFI_MEDIA_CHANGED	The device has a different medium in it or the medium is no longer supported.
EFI_DEVICE_ERROR	The device reported an error.
EFI_VOLUME_CORRUPTED	The file system structures are corrupted.

continues on next page

Table 13.4 – continued from previous page

EFI_WRITE_PROTECTED	An attempt was made to create a file, or open a file for write when the media is write-protected.
EFI_ACCESS_DENIED	The service denied access to the file.
EFI_OUT_OF_RESOURCES	Not enough resources were available to open the file.
EFI_VOLUME_FULL	The volume is full.

13.5.3 EFI_FILE_PROTOCOL.Close()

Summary

Closes a specified file handle.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_FILE_CLOSE) (
  IN EFI_FILE_PROTOCOL                          *This
  );
```

Parameters

This

A pointer to the *EFI_FILE_PROTOCOL* instance that is the file handle to close. See the type EFI_FILE_PROTOCOL description.

Description

The Close() function closes a specified file handle. All "dirty" cached file data is flushed to the device, and the file is closed. In all cases the handle is closed. The operation will wait for all pending asynchronous I/O requests to complete before completing.

Status Codes Returned

EFI_SUCCESS	The file was closed.

13.5.4 EFI_FILE_PROTOCOL.Delete()

Summary

Closes and deletes a file.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_FILE_DELETE) (
  IN EFI_FILE_PROTOCOL                          *This
  );
```

Parameters

This

A pointer to the *EFI_FILE_PROTOCOL* instance that is the handle to the file to delete. See the type EFI_FILE_PROTOCOL description.

Description

The Delete() function closes and deletes a file. In all cases the file handle is closed. If the file cannot be deleted, the warning code EFI_WARN_DELETE_FAILURE is returned, but the handle is still closed.

Status Codes Returned

EFI_SUCCESS	The file was closed and deleted, and the handle was closed.
EFI_WARN_DELETE_FAILURE	The handle was closed, but the file was not deleted.

13.5.5 EFI_FILE_PROTOCOL.Read()

Summary

Reads data from a file.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_FILE_READ) (
  IN EFI_FILE_PROTOCOL           *This,
  IN OUT UINTN                   *BufferSize,
  OUT VOID                       *Buffer
  );
```

Parameters

This

A pointer to the *EFI_FILE_PROTOCOL* instance that is the file handle to read data from. See the type EFI_FILE_PROTOCOL description.

BufferSize

On input, the size of the Buffer. On output, the amount of data returned in Buffer. In both cases, the size ismeasured in bytes.

Buffer

The buffer into which the data is read.

Description

The Read() function reads data from a file.

If This is not a directory, the function reads the requested number of bytes from the file at the file's current position and returns them in Buffer. If the read goes beyond the end of the file, the read length is truncated to the end of the file. The file's current position is increased by the number of bytes returned.

If This is a directory, the function reads the directory entry at the file's current position and returns the entry in Buffer. If the Buffer is not large enough to hold the current directory entry, then EFI_BUFFER_TOO_SMALL is returned and the current file position is not updated. BufferSize is set to be the size of the buffer needed to read the entry. On success, the current position is updated to the next directory entry. If there are no more directory entries, the read returns a zero-length buffer. *EFI_FILE_INFO* is the structure returned as the directory entry.

Status Codes Returned

EFI_SUCCESS	The data was read.
EFI_NO_MEDIA	The device has no medium.

continues on next page

Table 13.6 – continued from previous page

EFI_DEVICE_ERROR	The device reported an error.
EFI_DEVICE_ERROR	An attempt was made to read from a deleted file.
EFI_DEVICE_ERROR	On entry, the current file position is beyond the end of the file.
EFI_VOLUME_CORRUPTED	The file system structures are corrupted.
EFI_BUFFER_TOO_SMALL	The BufferSize is too small to read the current directory entry. BufferSize has been updated with the size needed to complete the request.

13.5.6 EFI_FILE_PROTOCOL.Write()

Summary

Writes data to a file.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_FILE_WRITE) (
  IN EFI_FILE_PROTOCOL              *This,
  IN OUT UINTN                      *BufferSize,
  IN VOID                           *Buffer
  );
```

Parameters

This

A pointer to the *EFI_FILE_PROTOCOL* instance that is the file handle to write data to. See the type EFI_FILE_PROTOCOL description.

BufferSize

On input, the size of the Buffer. On output, the amount of data actually written. In both cases, the size is measured in bytes.

Buffer

The buffer of data to write.

Description

The Write() function writes the specified number of bytes to the file at the current file position. The current file position is advanced the actual number of bytes written, which is returned in BufferSize. Partial writes only occur when there has been a data error during the write attempt (such as “file space full”). The file is automatically grown to hold the data if required.

Direct writes to opened directories are not supported.

Status Codes Returned

EFI_SUCCESS	The data was written.
EFI_UNSUPPORT	Writes to open directory files are not supported.
EFI_NO_MEDIA	The device has no medium.
EFI_DEVICE_ERROR	The device reported an error.
EFI_DEVICE_ERROR	An attempt was made to write to a deleted file.
EFI_VOLUME_CORRUPTED	The file system structures are corrupted.
EFI_WRITE_PROTECTED	The file or medium is write-protected.
EFI_ACCESS_DENIED	The file was opened read only.

Table 13.7 – continued from previous page

EFI_VOLUME_FULL	The volume is full.

13.5.7 EFI_FILE_PROTOCOL.OpenEx()

Summary

Opens a new file relative to the source directory's location.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_FILE_OPEN_EX) (
IN EFI_FILE_PROTOCOL                  *This,
OUT EFI_FILE_PROTOCOL                 **NewHandle,
IN CHAR16                             *FileName,
IN UINT64                             OpenMode,
IN UINT64                             Attributes,
IN OUT EFI_FILE_IO_TOKEN              *Token
);
```

Parameters

This

A pointer to the *EFI_FILE_PROTOCOL* instance that is the file handle to read data from. See the type *EFI_FILE_PROTOCOL* description

NewHandle

A pointer to the location to return the opened handle for the new file. See the type *EFI_FILE_PROTOCOL* description. For asynchronous I/O, this pointer must remain valid for the duration of the asynchronous operation.

FileName

The Null-terminated string of the name of the file to be opened. The file name may contain the following path modifiers: “", “.”, and “..”.

OpenMode

The mode to open the file. The only valid combinations that the file may be opened with are: Read, Read/Write, or Create/Read/Write. See “Related Definitions” below.

Attributes

Only valid for *EFI_FILE_MODE_CREATE,* in which case these are the attribute bits for the

Token

A pointer to the token associated with the transaction. Type *EFI_FILE_IO_TOKEN* is defined in “Related Definitions” below.

Description

The *OpenEx()* function opens the file or directory referred to by *FileName* relative to the location of This and returns a *NewHandle*. The *FileName* may include the path modifiers described previously in *Open()*.

If *EFI_FILE_MODE_CREATE* is set, then the file is created in the directory. If the final location of *FileName* does not refer to a directory, then the operation fails. If the file does not exist in the directory, then a new file is created. If the file already exists in the directory, then the existing file is opened.

If the medium of the device changes, all accesses (including the *File* handle) will result in *EFI_MEDIA_CHANGED*. To access the new medium, the volume must be reopened.

If an error is returned from the call to *OpenEx()* and non-blocking I/O is being requested, the Event associated with this request will not be signaled. If the call to *OpenEx()* succeeds then the *Event* will be signaled upon completion of the open or if an error occurs during the processing of the request. The status of the read request can be determined from the Status field of the Token once the event is signaled.

Related Definitions

```
typedef struct {
  EFI_EVENT                          Event;
  EFI_STATUS                         Status;
  UINTN                              BufferSize;
  VOID                               *Buffer;
  } EFI_FILE_IO_TOKEN;
```

Event

If *Event* is **NULL**, then blocking I/O is performed. If *Event* is not **NULL** and non-blocking I/O is supported, then non-blocking I/O is performed, and *Event* will be signaled when the read request is completed. The caller must be prepared to handle the case where the callback associated with *Event* occurs before the original asynchronous I/O request call returns.

Status

Defines whether or not the signaled event encountered an error.

BufferSize

For OpenEx() : Not Used, ignored

For ReadEx() :On input, the size of the *Buffer*. On output, the amount of data returned in *Buffer*. In both cases, the size is measured in bytes.

For WriteEx() : On input, the size of the *Buffer*. On output, the amount of data actually written. In both cases, the size is measured in bytes.

For FlushEx() : Not used, ignored

Buffer

For OpenEx(): Not Used, ignored

For ReadEx() : The buffer into which the data is read.

For WriteEx() : The buffer of data to write.

For FlushEx() : Not Used, ignored

Status Codes Returned

EFI_SUCCESS	Returned from the call *OpenEx()* If *Event* is NULL (blocking I/O): The file was opened successfully. If *Event* is not NULL (asynchronous I/O): The request was successfully queued for processing. *Event* will be signaled upon completion. Returned in the token after signaling *Event* The file was opened successfully.
EFI_NOT_FOUND	The device has no medium.
EFI_NO_MEDIA	The specified file could not be found on the device.
EFI_VOLUME_CORRUPTED	The file system structures are corrupted.

continues on next page

Table 13.8 – continued from previous page

EFI_WRITE_PROTECTED	An attempt was made to create a file, or open a file for write when the media is write-protected.
EFI_ACCESS_DENIED	The service denied access to the file.
EFI_OUT_OF_RESOURCES	Unable to queue the request or open the file due to lack of resources.
EFI_VOLUME_FULL	The volume is full.

13.5.8 EFI_FILE_PROTOCOL.ReadEx()

Summary

Reads data from a file.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_FILE_READ_EX) (
  IN EFI_FILE_PROTOCOL                      *This,
  IN OUT EFI_FILE_IO_TOKEN                  *Token
  );
```

Parameters

This

A pointer to the *EFI_FILE_PROTOCOL* instance that is the file handle to read data from. See the type *EFI_FILE_PROTOCOL* description.

Token

A pointer to the token associated with the transaction. Type EFI_FILE_IO_TOKEN is defined in “Related Definitions” below.

Description

The *ReadEx()* function reads data from a file.

If This is not a directory, the function reads the requested number of bytes from the file at the file’s current position and returns them in *Buffer* . If the read goes beyond the end of the file, the read length is truncated to the end of the file. The file’s current position is increased by the number of bytes returned.

If This is a directory, the function reads the directory entry at the file’s current position and returns the entry in* *Buffer*. If the *Buffer* is not large enough to hold the current directory entry, then *EFI_BUFFER_TOO_SMALL* is returned and the current file position is not updated. *BufferSize* is set to be the size of the buffer needed to read the entry. On success, the current position is updated to the next directory entry. If there are no more directory entries, the read returns a zero-length buffer. *EFI_FILE_INFO* is the structure returned as the directory entry.

If non-blocking I/O is used the file pointer will be advanced based on the order that read requests were submitted.

If an error is returned from the call to *ReadEx()* and non-blocking I/O is being requested, the Event associated with this request will not be signaled. If the call to *ReadEx()* succeeds then the *Event* will be signaled upon completion of the read or if an error occurs during the processing of the request. The status of the read request can be determined from the *Status* field of the *Token* once the event is signaled.

Status Codes Returned

EFI_SUCCESS	Returned from the call *ReadEx()* If *Event* is NULL (blocking I/O): The data was read successfully. If *Event* is not NULL (asynchronous I/O): The request was successfully queued for processing. Event will be signaled upon completion. Returned in the token after signaling *Event* The data was read successfully.
EFI_NO_MEDIA	The device has no medium.
EFI_DEVICE_ERROR	The device reported an error.
EFI_DEVICE_ERROR	An attempt was made to read from a deleted file.
EFI_DEVICE_ERROR	On entry, the current file position is beyond the end of the file.
EFI_VOLUME_CORRUPTED	The file system structures are corrupted.
EFI_OUT_OF_RESOURCES	Unable to queue the request due to lack of resources.

13.5.9 EFI_FILE_PROTOCOL.WriteEx()

Summary

Writes data to a file.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_FILE_WRITE_EX) (
  IN EFI_FILE_PROTOCOL                *This,
  IN OUT EFI_FILE_IO_TOKEN            *Token
  );
```

Parameters

This

A pointer to the *EFI_FILE_PROTOCOL* instance that is the file handle to write data to. See the type *EFI_FILE_PROTOCOL* description.

Token

A pointer to the token associated with the transaction. Type *EFI_FILE_IO_TOKEN* is defined in “Related Definitions” above.

Description

The *WriteEx()* function writes the specified number of bytes to the file at the current file position. The current file position is advanced the actual number of bytes written, which is returned in *BufferSize*. Partial writes only occur when there has been a data error during the write attempt (such as “file space full”). The file is automatically grown to hold the data if required.

Direct writes to opened directories are not supported.

If non-blocking I/O is used the file pointer will be advanced based on the order that write requests were submitted.

If an error is returned from the call to *WriteEx()* and non-blocking I/O is being requested, the *Event* associated with this request will not be signaled. If the call to *WriteEx()* succeeds then the *Event* will be signaled upon completion of the write or if an error occurs during the processing of the request. The status of the write request can be determined from the *Status* field of the *Token* once the event is signaled.

Status Codes Returned

EFI_SUCCESS	Returned from the call *WriteEx()* If *Event* is NULL (blocking I/O): The data was written successfully. If *Event* is not NULL (asynchronous I/O): The request was successfully queued for processing. *Event* will be signaled upon completion. Returned in the token after signaling *Event* The data was written successfully.
EFI_UNSUPPORTED	Writes to open directory files are not supported.
EFI_NO_MEDIA	The device has no medium.
EFI_DEVICE_ERROR	The device reported an error.
EFI_DEVICE_ERROR	An attempt was made to write to a deleted file.
EFI_VOLUME_CORRUPTED	The file system structures are corrupted.
EFI_WRITE_PROTECTED	The file or medium is write-protected.
EFI_ACCESS_DENIED	The file was opened read only.
EFI_VOLUME_FULL	The volume is full.
EFI_OUT_OF_RESOURCES	Unable to queue the request due to lack of resources.

13.5.10 EFI_FILE_PROTOCOL.FlushEx()

Summary

Flushes all modified data associated with a file to a device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_FILE_FLUSH_EX) (
  IN EFI_FILE_PROTOCOL                        *This,
  IN OUT EFI_FILE_IO_TOKEN                    *Token
  );
```

Parameters

This

A pointer to the *EFI_FILE_PROTOCOL* instance that is the file handle to flush. See the type *EFI_FILE_PROTOCOL* description.

Token

A pointer to the token associated with the transaction. Type *EFI_FILE_IO_TOKEN* is defined in "Related Definitions" above. The *BufferSize* and *Buffer* fields are not used for a *FlushEx* operation.

Description

The *FlushEx()* function flushes all modified data associated with a file to a device.

For non-blocking I/O all writes submitted before the flush request will be flushed.

If an error is returned from the call to *FlushEx()* and non-blocking I/O is being requested, the *Event* associated with this request will not be signaled.

Status Codes Returned

EFI_SUCCESS	Returned from the call *FlushEx()* If *Event* is NULL (blocking I/O): The data was flushed successfully. If *Event* is not NULL (asynchronous I/O): The request was successfully queued for processing. Event will be signaled upon completion. Returned in the token after signaling *Event* The data was flushed successfully.
EFI_NO_MEDIA	The device has no medium.
EFI_DEVICE_ERROR	The device reported an error.
EFI_VOLUME_CORRUPTED	The file system structures are corrupted.
EFI_WRITE_PROTECTED	The file or medium is write-protected.
EFI_ACCESS_DENIED	The file was opened read-only.
EFI_VOLUME_FULL	The volume is full.
EFI_OUT_OF_RESOURCES	Unable to queue the request due to lack of resources.

13.5.11 EFI_FILE_PROTOCOL.SetPosition()

Summary

Sets a file's current position.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_FILE_SET_POSITION) (
   IN EFI_FILE_PROTOCOL      *This,
   IN UINT64                 Position
   );
```

Parameters

This

A pointer to the *EFI_FILE_PROTOCOL* instance that is the he file handle to set the requested position on. See the type EFI_FILE_PROTOCOL description.

Position

The byte position from the start of the file to set.

Description

The SetPosition() function sets the current file position for the handle to the position supplied. With the exception of seeking to position 0xFFFFFFFFFFFFFFFF, only absolute positioning is supported, and seeking past the end of the file is allowed (a subsequent write would grow the file). Seeking to position 0xFFFFFFFFFFFFFFFF causes the current position to be set to the end of the file.

If This is a directory, the only position that may be set is zero. This has the effect of starting the read process of the directory entries over.

Status Codes Returned

EFI_SUCCESS	The position was set.
EFI_UNSUPPORTED	The seek request for nonzero is not valid on open directories.
EFI_DEVICE_ERROR	An attempt was made to set the position of a deleted file.

13.5.12 EFI_FILE_PROTOCOL.GetPosition()

Summary

Returns a file's current position.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_FILE_GET_POSITION) (
  IN EFI_FILE_PROTOCOL                *This,
  OUT UINT64                          *Position
  );
```

Parameters

This

A pointer to the *EFI_FILE_PROTOCOL* instance that is the file handle to get the current position on. See the type EFI_FILE_PROTOCOL description.

Position

The address to return the file's current position value.

Description

The GetPosition() function returns the current file position for the file handle. For directories, the current file position has no meaning outside of the file system driver and as such the operation is not supported. An error is returned if This is a directory.

Status Codes Returned

EFI_SUCCESS	The position was returned.
EFI_UNSUPPORTED	The request is not valid on open directories.
EFI_DEVICE_ERROR	An attempt was made to get the position from a deleted file.

13.5.13 EFI_FILE_PROTOCOL.GetInfo()

Summary

Returns information about a file.

Prototype

```
typedef
EFI_STATUS
```

(continues on next page)

(continued from previous page)

```
(EFIAPI *EFI_FILE_GET_INFO) (
  IN EFI_FILE_PROTOCOL            *This,
  IN EFI_GUID                     *InformationType,
  IN OUT UINTN                    *BufferSize,
  OUT VOID                        *Buffer
  );
```

Parameters

This

A pointer to the *EFI_FILE_PROTOCOL* instance that is the file handle the requested information is for. See the type EFI_FILE_PROTOCOL description.

InformationType

The type identifier for the information being requested. Type EFI_GUID is defined on page 181. See the *EFI_FILE_INFO* and *EFI_FILE_SYSTEM_INFO* descriptions for the related GUID definitions.

BufferSize

On input, the size of Buffer. On output, the amount of data returned in Buffer. In both cases, the size is measured in bytes.

Buffer

A pointer to the data buffer to return. The buffer's type is indicated by InformationType.

Description

The GetInfo() function returns information of type InformationType for the requested file. If the file does not support the requested information type, then EFI_UNSUPPORTED is returned. If the buffer is not large enough to fit the requested structure, EFI_BUFFER_TOO_SMALL is returned and the BufferSize is set to the size of buffer that is required to make the request.

The information types defined by this specification are required information types that all file systems must support.

Status Codes Returned

EFI_SUCCESS	The information was set.
EFI_UNSUPPORTED	The InformationType is not known.
EFI_NO_MEDIA	The device has no medium.
EFI_DEVICE_ERROR	The device reported an error.
EFI_VOLUME_CORRUPTED	The file system structures are corrupted.
EFI_BUFFER_TOO_SMALL	The BufferSize is too small to read the current directory entry. BufferSize has been updated with the size needed to complete the request.

13.5.14 EFI_FILE_PROTOCOL.SetInfo()

Summary

Sets information about a file.

Prototype

```
typedef
EFI_STATUS
```

(continues on next page)

(continued from previous page)

```
(EFIAPI *EFI_FILE_SET_INFO) (
  IN EFI_FILE_PROTOCOL              *This,
  IN EFI_GUID                       *InformationType,
  IN UINTN                          BufferSize,
  IN VOID                           *Buffer
  );
```

Parameters

This
A pointer to the *EFI_FILE_PROTOCOL* instance that is the file handle the information is for. See the type EFI_FILE_PROTOCOL description.

InformationType
The type identifier for the information being set. Type EFI_GUID is defined in page 181. See the *EFI_FILE_INFO* and *EFI_FILE_SYSTEM_INFO* descriptions in this section for the related GUID definitions.

BufferSize
The size, in bytes, of Buffer

Buffer
A pointer to the data buffer to write. The buffer's type is indicated by InformationType.

Description

The SetInfo() function sets information of type InformationType on the requested file. Because a read-only file can be opened only in read-only mode, an *InformationType* of *EFI_FILE_INFO_ID* can be used with a read-only file because this method is the only one that can be used to convert a read-only file to a read-write file. In this circumstance, only the *Attribute* field of the *EFI_FILE_INFO* structure may be modified. One or more calls to *SetInfo()* to change the *Attribute* field are permitted before it is closed. The file attributes will be valid the next time the file is opened with *Open()*.

An *InformationType* of *EFI_FILE_SYSTEM_INFO_ID* or *EFI_FILE_SYSTEM_VOLUME_LABEL_ID* may not be used on read-only media.

Status Codes Returned

EFI_SUCCESS	The information was set.
EFI_UNSUPPORTED	The InformationType is not known.
EFI_NO_MEDIA	The device has no medium.
EFI_DEVICE_ERROR	The device reported an error.
EFI_VOLUME_CORRUPTED	The file system structures are corrupted.
EFI_WRITE_PROTECTED	*InformationType* is *EFI_FILE_INFO_ID* and the media is read-only.
EFI_WRITE_PROTECTED	*InformationType* is *EFI_FILE_PROTOCOL_SYSTEM_INFO_ID* and the media is read only.
EFI_WRITE_PROTECTED	*InformationType* is *EFI_FILE_SYSTEM_VOLUME_LABEL_ID* and the media is read-only.
EFI_ACCESS_DENIED	An attempt is made to change the name of a file to a file that is already present.
EFI_ACCESS_DENIED	An attempt is being made to change the *EFI_FILE_DIRECTORY Attribute*.
EFI_ACCESS_DENIED	An attempt is being made to change the size of a directory.
EFI_ACCESS_DENIED	*InformationType* is *EFI_FILE_INFO_ID* and the file was opened read-only and an attempt is being made to modify a field other than *Attribute*.
EFI_VOLUME_FULL	The volume is full.
EFI_BAD_BUFFER_SIZE	BufferSize is smaller than the size of the type indicated by InformationType.

13.5.15 EFI_FILE_PROTOCOL.Flush()

Summary

Flushes all modified data associated with a file to a device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_FILE_FLUSH) (
  IN EFI_FILE_PROTOCOL              *This
  );
```

Parameters

This

A pointer to the *EFI_FILE_PROTOCOL* instance that is the file handle to flush. See the type EFI_FILE_PROTOCOL description.

Description

The Flush() function flushes all modified data associated with a file to a device.

Status Codes Returned

EFI_SUCCESS	The data was flushed.
EFI_NO_MEDIA	The device has no medium.
EFI_DEVICE_ERROR	The device reported an error.
EFI_VOLUME_CORRUPTED	The file system structures are corrupted.
EFI_WRITE_PROTECTED	The file or medium is write-protected.
EFI_ACCESS_DENIED	The file was opened read-only.
EFI_VOLUME_FULL	The volume is full.

13.5.16 EFI_FILE_INFO

Summary

Provides a GUID and a data structure that can be used with *EFI_FILE_PROTOCOL.SetInfo()* and *EFI_FILE_PROTOCOL.GetInfo()* to set or get generic file information.

GUID

```
#define EFI_FILE_INFO_ID \
 {0x09576e92,0x6d3f,0x11d2,\
  {0x8e39,0x00,0xa0,0xc9,0x69,0x72,0x3b}}
```

Related Definitions

```
typedef struct {
  UINT64                        Size;
  UINT64                        FileSize;
  UINT64                        PhysicalSize;
  EFI_TIME                      CreateTime;
  EFI_TIME                      LastAccessTime;
  EFI_TIME                      ModificationTime;
```

(continues on next page)

(continued from previous page)

```
  UINT64                        Attribute;
  CHAR16                        FileName [];
} EFI_FILE_INFO;

//*******************************************
// File Attribute Bits
//*******************************************

#define EFI_FILE_READ_ONLY      0x0000000000000001
#define EFI_FILE_HIDDEN         0x0000000000000002
#define EFI_FILE_SYSTEM         0x0000000000000004
#define EFI_FILE_RESERVED       0x0000000000000008
#define EFI_FILE_DIRECTORY      0x0000000000000010
#define EFI_FILE_ARCHIVE        0x0000000000000020
#define EFI_FILE_VALID_ATTR     0x0000000000000037
```

Parameters

Size
Size of the EFI_FILE_INFO structure, including the Null-terminated FileName string.

FileSize
The size of the file in bytes.

PhysicalSize
The amount of physical space the file consumes on the file system volume.

CreateTime
The time the file was created.

LastAccessTime
The time when the file was last accessed.

ModificationTime
The time when the file's contents were last modified.

Attribute
The attribute bits for the file. See "Related Definitions" above.

FileName
The Null-terminated name of the file. For a root directory, the name is an empty string.

Description

The EFI_FILE_INFO data structure supports *EFI_FILE_PROTOCOL.GetInfo()* and *EFI_FILE_PROTOCOL.SetInfo()* requests. In the case of SetInfo(), the following additional rules apply:

- On directories, the file size is determined by the contents of the directory and cannot be changed by setting FileSize. On directories, FileSize is ignored during a SetInfo().
- The PhysicalSize is determined by the FileSize and cannot be changed. This value is ignored during a SetInfo() request.
- The EFI_FILE_DIRECTORY attribute bit cannot be changed. It must match the file's actual type.
- A value of zero in CreateTime, LastAccess, or ModificationTime causes the fields to be ignored (and not updated).

13.5.17 EFI_FILE_SYSTEM_INFO

Summary

Provides a GUID and a data structure that can be used with *EFI_FILE_PROTOCOL.GetInfo()* to get information about the system volume, and *EFI_FILE_PROTOCOL.SetInfo()* to set the system volume's volume label.

GUID

```
#define EFI_FILE_SYSTEM_INFO_ID \
 {0x09576e93,0x6d3f,0x11d2,0x8e39,0x00,0xa0,0xc9,0x69,0x72,\
 0x3b}
```

Related Definitions

```
typedef struct {
  UINT64                                 Size;
  BOOLEAN                                ReadOnly;
  UINT64                                 VolumeSize;
  UINT64                                 FreeSpace;
  UINT32                                 BlockSize;
  CHAR16                                 VolumeLabel[];
} EFI_FILE_SYSTEM_INFO;
```

Parameters

Size
Size of the EFI_FILE_SYSTEM_INFO structure, including he Null-terminated VolumeLabel string.

ReadOnly
TRUE if the volume only supports read access.

VolumeSize
The number of bytes managed by the file system.

FreeSpace
The number of available bytes for use by the file system.

BlockSize
The nominal block size by which files are typically grown.

VolumeLabel
The Null-terminated string that is the volume's label.

Description

The EFI_FILE_SYSTEM_INFO data structure is an information structure that can be obtained on the root directory file handle. The root directory file handle is the file handle first obtained on the initial call to the *EFI_BOOT_SERVICES.HandleProtocol()* function to open the file system interface. All of the fields are read-only except for VolumeLabel. The system volume's VolumeLabel can be created or modified by calling EFI_FILE_PROTOCOL.SetInfo() with an updated VolumeLabel field.

13.5.18 EFI_FILE_SYSTEM_VOLUME_LABEL

Summary

Provides a GUID and a data structure that can be used with *EFI_FILE_PROTOCOL.GetInfo()* or *EFI_FILE_PROTOCOL.SetInfo()* to get or set information about the system's volume label.

GUID

```
#define EFI_FILE_SYSTEM_VOLUME_LABEL_ID \
 {0xdb47d7d3,0xfe81,0x11d3,0x9a35,\
  {0x00,0x90,0x27,0x3f,0xC1,0x4d}}
```

Related Definitions

```
typedef struct {
 CHAR16                             VolumeLabel[];
} EFI_FILE_SYSTEM_VOLUME_LABEL;
```

Parameters

VolumeLabel
The Null-terminated string that is the volume's label.

Description

The EFI_FILE_SYSTEM_VOLUME_LABEL data structure is an information structure that can be obtained on the root directory file handle. The root directory file handle is the file handle first obtained on the initial call to the TODO LINK See *EFI_BOOT_SERVICES.HandleProtocol()* function to open the file system interface. The system volume's VolumeLabel can be created or modified by calling EFI_FILE_PROTOCOL.SetInfo() with an updated VolumeLabel field.

13.6 Tape Boot Support

13.6.1 Tape I/O Support

This section defines the Tape I/O Protocol and standard tape header format. These enable the support of booting from tape on UEFI systems. This protocol is used to abstract the tape drive operations to support applications written to this specification.

13.6.2 Tape I/O Protocol

This section defines the Tape I/O Protocol and its functions. This protocol is used to abstract the tape drive operations to support applications written to this specification.

13.6.2.1 EFI_TAPE_IO_PROTOCOL

Summary

The EFI Tape IO protocol provides services to control and access a tape device.

GUID

```
#define EFI_TAPE_IO_PROTOCOL_GUID \
 {0x1e93e633,0xd65a,0x459e, \
  {0xab,0x84,0x93,0xd9,0xec,0x26,0x6d,0x18}}
```

Protocol Interface Structure

```
typedef struct_EFI_TAPE_IO_PROTOCOL {
  EFI_TAPE_READ        TapeRead;
  EFI_TAPE_WRITE       TapeWrite;
  EFI_TAPE_REWIND      TapeRewind;
  EFI_TAPE_SPACE       TapeSpace;
  EFI_TAPE_WRITEFM     TapeWriteFM;
  EFI_TAPE_RESET       TapeReset;
} EFI_TAPE_IO_PROTOCOL;
```

Parameters

TapeRead
Read a block of data from the tape. See the *EFI_TAPE_IO_PROTOCOL.TapeRead()* description.

TapeWrite
Write a block of data to the tape. See the *EFI_TAPE_IO_PROTOCOL.TapeWrite()* description.

TapeRewind
Rewind the tape. See the *EFI_TAPE_IO_PROTOCOL.TapeRewind()* description.

TapeSpace
Position the tape. See the *EFI_TAPE_IO_PROTOCOL.TapeSpace()* description.

TapeWriteFM
Write filemarks to the tape. See the *EFI_TAPE_IO_PROTOCOL.TapeWriteFM()* description.

TapeReset
Reset the tape device or its parent bus. See the *EFI_TAPE_IO_PROTOCOL.TapeReset()* description.

Description

The EFI_TAPE_IO_PROTOCOL provides basic sequential operations for tape devices. These include read, write, rewind, space, write filemarks and reset functions. Per this specification, a boot application uses the services of this protocol to load the bootloader image from tape.

No provision is made for controlling or determining media density or compression settings. The protocol relies on devices to behave normally and select settings appropriate for the media loaded. No support is included for tape partition support, setmarks or other tapemarks such as End of Data. Boot tapes are expected to use normal variable or fixed block size formatting and filemarks.

13.6.2.2 EFI_TAPE_IO_PROTOCOL.TapeRead()

Summary

Reads from the tape.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_TAPE_READ) (
  IN EFI_TAPE_IO_PROTOCOL         *This,
  IN OUT UINTN                    *BufferSize,
  OUT VOID                        *Buffer
  );
```

Parameters

This
A pointer to the *EFI_TAPE_IO_PROTOCOL* instance.

BufferSize
Size of the buffer in bytes pointed to by *Buffer*

Buffer
Pointer to the buffer for data to be read into.

Description

This function will read up to *BufferSize* bytes from media into the buffer pointed to by *Buffer* using an implementation-specific timeout. *BufferSize* will be updated with the number of bytes transferred.

Each read operation for a device that operates in variable block size mode reads one media data block. Unread bytes which do not fit in the buffer will be skipped by the next read operation. The number of bytes transferred will be limited by the actual media block size. Best practice is for the buffer size to match the media data block size. When a filemark is encountered in variable block size mode the read operation will indicate that 0 bytes were transferred and the function will return an *EFI_END_OF_FILE* error condition.

In fixed block mode the buffer is expected to be a multiple of the data block size. Each read operation for a device that operates in fixed block size mode may read multiple media data blocks. The number of bytes transferred will be limited to an integral number of complete media data blocks. *BufferSize* should be evenly divisible by the device's fixed block size. When a filemark is encountered in fixed block size mode the read operation will indicate that the number of bytes transferred is less than the number of blocks that would fit in the provided buffer (possibly 0 bytes transferred) and the function will return an *EFI_END_OF_FILE* error condition.

Two consecutive filemarks are normally used to indicate the end of the last file on the media.

The value specified for *BufferSize* should correspond to the actual block size used on the media. If necessary, the value for *BufferSize* may be larger than the actual media block size.

Specifying a *BufferSize* of 0 is valid but requests the function to provide read-related status information instead of actual media data transfer. No data will be attempted to be read from the device however this operation is classified as an access for status handling. The status code returned may be used to determine if a filemark has been encountered by the last read request with a non-zero size, and to determine if media is loaded and the device is ready for reading. A **NULL** value for *Buffer* is valid when *BufferSize* is zero.

Status Codes Returned

EFI_SUCCESS	Data was successfully transferred from the media.

continues on next page

Table 13.17 – continued from previous page

EFI_END_OF_FILE	A filemark was encountered which limited the data transferred by the read operation or the head is positioned just after a filemark.
EFI_NO_MEDIA	No media is loaded in the device.
EFI_MEDIA_CHANGED	The media in the device was changed since the last access. The transfer was aborted since the current position of the media may be incorrect.
EFI_DEVICE_ERROR	A device error occurred while attempting to transfer data from the media.
EFI_INVALID_PARAMETER	A *NULL Buffer* was specified with a non-zero *BufferSize* or the device is operating in fixed block size mode and the *BufferSize* was not a multiple of device's fixed block size
EFI_NOT_READY	The transfer failed since the device was not ready (e.g. not online). The transfer may be retried at a later time.
EFI_UNSUPPORTED	The device does not support this type of transfer.
EFI_TIMEOUT	The transfer failed to complete within the timeout specified.

13.6.2.3 EFI_TAPE_IO_PROTOCOL.TapeWrite()

Summary

Write to the tape.

Prototype

```
Typedef EFI_STATUS
(EFIAPI *EFI_TAPE_WRITE) (
  IN EFI_TAPE_IO_PROTOCOL          *This,
  IN UINTN                         *BufferSize,
  IN VOID                          *Buffer
  );
```

Parameters

This
A pointer to the *EFI_TAPE_IO_PROTOCOL* instance.

BufferSize
Size of the buffer in bytes pointed to by *Buffer*.

Buffer
Pointer to the buffer for data to be written from.

Description

This function will write *BufferSize* bytes from the buffer pointed to by *Buffer* to media using an implementation-specific timeout.

Each write operation for a device that operates in variable block size mode writes one media data block of *BufferSize* bytes.

Each write operation for a device that operates in fixed block size mode writes one or more media data blocks of the device's fixed block size. *BufferSize* must be evenly divisible by the device's fixed block size.

Although sequential devices in variable block size mode support a wide variety of block sizes, many issues may be avoided in I/O software, adapters, hardware and firmware if common block sizes are used such as: 32768, 16384, 8192, 4096, 2048, 1024, 512, and 80.

BufferSize will be updated with the number of bytes transferred.

When a write operation occurs beyond the logical end of media an *EFI_END_OF_MEDIA* error condition will occur. Normally data will be successfully written and *BufferSize* will be updated with the number of bytes transferred. Additional write operations will continue to fail in the same manner. Excessive writing beyond the logical end of media should be avoided since the physical end of media may be reached.

Specifying a *BufferSize* of 0 is valid but requests the function to provide write-related status information instead of actual media data transfer. No data will be attempted to be written to the device however this operation is classified as an access for status handling. The status code returned may be used to determine if media is loaded, writable and if the logical end of media point has been reached. A **NULL** value for *Buffer* is valid when *BufferSize* is zero.

Status Codes Returned

EFI_SUCCESS	Data was successfully transferred to the media.
EFI_END_OF_MEDIA	The logical end of media has been reached. Data may have been successfully transferred to the media.
EFI_NO_MEDIA	No media is loaded in the device.
EFI_MEDIA_CHANGED	The media in the device was changed since the last access. The transfer was aborted since the current position of the media may be incorrect.
EFI_WRITE_PROTECTED	The media in the device is write-protected. The transfer was aborted since a write cannot be completed.
EFI_DEVICE_ERROR	A device error occurred while attempting to transfer data from the media.
EFI_INVALID_PARAMETER	A *NULL Buffer* was specified with a non-zero *BufferSize* or the device is operating in fixed block size mode and *BufferSize* was not a multiple of device's fixed block size.
EFI_NOT_READY	The transfer failed since the device was not ready (e.g. not online). The transfer may be retried at a later time.
EFI_UNSUPPORTED	The device does not support this type of transfer.
EFI_TIMEOUT	The transfer failed to complete within the timeout specified.

13.6.2.4 EFI_TAPE_IO_PROTOCOL.TapeRewind()

Summary

Rewinds the tape.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_TAPE_REWIND) (
  IN EFI_TAPE_IO_PROTOCOL       *This,
  );
```

Parameters

This

A pointer to the *EFI_TAPE_IO_PROTOCOL* instance.

Description

This function will rewind the media using an implementation-specific timeout. The function will check if the media was changed since the last access and reinstall the *EFI_TAPE_IO_PROTOCOL* interface for the device handle if needed.

Status Codes Returned

EFI_SUCCESS	The media was successfully repositioned.
EFI_NO_MEDIA	No media is loaded in the device.
EFI_DEVICE_ERROR	A device error occurred while attempting to reposition the media.
EFI_NOT_READY	Repositioning the media failed since the device was not ready (e.g. not on-line). The transfer may be retried at a later time.
EFI_UNSUPPORTED	The device does not support this type of media repositioning.
EFI_TIMEOUT	Repositioning of the media did not complete within the timeout specified.

13.6.2.5 EFI_TAPE_IO_PROTOCOL.TapeSpace()

Summary

Positions the tape.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_TAPE_SPACE) (
  IN EFI_TAPE_IO_PROTOCOL       *This,
  IN INTN                       Direction,
  IN UINTN                      Type
  );
```

Parameters

This
A pointer to the *EFI_TAPE_IO_PROTOCOL* instance.

Direction
Direction and number of data blocks or filemarks to space over on media.

Type
Type of mark to space over on media.

Description

This function will position the media using an implementation-specific timeout.

A positive *Direction* value will indicate the number of data blocks or filemarks to forward space the media. A negative *Direction* value will indicate the number of data blocks or filemarks to reverse space the media.

The following **Type** marks are mandatory:

Type of Tape	Mark MarkType
BLOCK	0
FILEMARK	1

Space operations position the media past the data block or filemark. Forward space operations leave media positioned with the tape device head after the data block or filemark. Reverse space operations leave the media positioned with the tape device head before the data block or filemark.

If beginning of media is reached before a reverse space operation passes the requested number of data blocks or filemarks an *EFI_END_OF_MEDIA* error condition will occur. If end of recorded data or end of physical media is reached before a forward space operation passes the requested number of data blocks or filemarks an *EFI_END_OF_MEDIA* error condition will occur. An *EFI_END_OF_MEDIA* error condition will not occur due to spacing over data blocks or filemarks past the logical end of media point used to indicate when write operations should be limited.

Status Codes Returned

EFI_SUCCESS	The media was successfully repositioned.
EFI_END_OF_MEDIA	Beginning or end of media was reached before the indicated number of data blocks or filemarks were found.
EFI_NO_MEDIA	No media is loaded in the device.
EFI_MEDIA_CHANGED	The media in the device was changed since the last access. Repositioning the media was aborted since the current position of the media may be incorrect.
EFI_DEVICE_ERROR	A device error occurred while attempting to reposition the media.
EFI_NOT_READY	Repositioning the media failed since the device was not ready (e.g. not online). The transfer may be retried at a later time.
EFI_UNSUPPORTED	The device does not support this type of media repositioning.
EFI_TIMEOUT	Repositioning of the media did not complete within the timeout specified.

13.6.2.6 EFI_TAPE_IO_PROTOCOL.TapeWriteFM()

Summary

Writes filemarks to the media.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_TAPE_WRITEFM) (
  IN EFI_TAPE_IO_PROTOCOL      *This,
  IN UINTN                     Count
  );
```

Parameters

This
A pointer to the *EFI_TAPE_IO_PROTOCOL* instance.

Count
Number of filemarks to write to the media.

Description

This function will write filemarks to the tape using an implementation-specific timeout.

Writing filemarks beyond logical end of tape does not result in an error condition unless physical end of media is reached.

Status Codes Returned

EFI_SUCCESS	Data was successfully transferred from the media.
EFI_NO_MEDIA	No media is loaded in the device.
EFI_MEDIA_CHANGED	The media in the device was changed since the last access. The transfer was aborted since the current position of the media may be incorrect.
EFI_DEVICE_ERROR	A device error occurred while attempting to transfer data from the media.
EFI_NOT_READY	The transfer failed since the device was not ready (e.g. not online). The transfer may be retried at a later time.
EFI_UNSUPPORTED	The device does not support this type of transfer.
EFI_TIMEOUT	The transfer failed to complete within the timeout specified.

13.6.2.7 EFI_TAPE_IO_PROTOCOL.TapeReset()

Summary

Resets the tape device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_TAPE_RESET) (
  IN EFI_TAPE_IO_PROTOCOL   *This,
  IN BOOLEAN                ExtendedVerification
  );
```

Parameters

This

A pointer to the *EFI_TAPE_IO_PROTOCOL* instance.

ExtendedVerification

Indicates whether the parent bus should also be reset.

Description

This function will reset the tape device. If *ExtendedVerification* is set to **TRUE**, the function will reset the parent bus (e.g., SCSI bus). The function will check if the media was changed since the last access and reinstall the *EFI_TAPE_IO_PROTOCOL* interface for the device handle if needed. Note media needs to be loaded and device online for the reset, otherwise, *EFI_DEVICE_ERROR* is returned.

Status Codes Returned

EFI_SUCCESS	The bus and/or device were successfully reset.
EFI_NO_MEDIA	No media is loaded in the device.
EFI_DEVICE_ERROR	A device error occurred while attempting to reset the bus and/or device.
EFI_NOT_READY	The reset failed since the device and/or bus was not ready. The reset may be retried at a later time.
EFI_UNSUPPORTED	The device does not support this type of reset.
EFI_TIMEOUT	The reset did not complete within the timeout allowed.

13.6.3 Tape Header Format

The boot tape will contain a Boot Tape Header to indicate it is a valid boot tape. The Boot Tape Header must be located within the first 20 blocks on the tape. One or more tape filemarks may appear prior to the Boot Tape Header so that boot tapes may include tape label files. The Boot Tape Header must begin on a block boundary and be contained completely within a block. The Boot Tape Header will have the following format:

Table 13.24: Tape Header Formats

Bytes (Dec)	Value	Purpose
0-7	0x544f4f4220494645	Signature (‘EFI BOOT’ in ASCII)
8-11	1	Revision
12-15	1024	Tape Header Size in bytes
16-19	calculated	Tape Header CRC

continues on next page

Table 13.24 – continued from previous page

20-35	{ 0x8befa29a, 0x3511, 0x4cf7, { 0xa2, 0xeb, 0x5f, 0xe3, 0x7c, 0x3b, 0xf5, 0x5b } }	EFI Boot Tape GUID (same for all EFI Boot Tapes, like EFI Disk GUID)
36-51	User Defined	EFI Boot Tape Type GUID (bootloader / OS specific, like EFI Partition Type GUID)
52-67	User Defined	EFI Boot Tape Unique GUID (unique for every EFI Boot Tape)
68-71	e.g. 2	File Number of EFI Bootloader relative to the Boot Tape Header (first file immediately after the Boot Tape Header is file number 1, ANSI labels are counted)
72-75	e.g. 0x400	EFI Bootloader Block Size in bytes
76-79	e.g. 0x20000	EFI Bootloader Total Size in bytes
80-119	e.g. HPUX 11.23	OS Version (ASCII)
120-159	e.g. Ignite-UX C.6.2.241	Application Version (ASCII)
160-169	e.g.1993-02-28	EFI Boot Tape creation date (UTC) (yyyy-mm-dd ASCII)
170-179	e.g. 13:24:55	EFI Boot Tape creation time (UTC) (hh:mm:ss in ASCII)
180-435	e.g. testsys1 (alt e.g. testsys1.xyzcorp.com)	Computer System Name (UTF-8, ref: RFC 2044)
436-555	e.g. Primary Disaster Recovery	Boot Tape Title / Comment (UTF-8, ref: RFC 2044)
556-1023	reserved	

All numeric values will be specified in binary format. Note that all values are specified in Little Endian byte ordering.

The Boot Tape Header can also be represented as the following data structure:

```
typedef struct EFI_TAPE_HEADER {
  UINT64          Signature;
  UINT32          Revision;
  UINT32          BootDescSize;
  UINT32          BootDescCRC;
  EFI_GUID        TapeGUID;
  EFI_GUID        TapeType;
  EFI_GUID        TapeUnique;
  UINT32          BLLocation;
  UINT32          BLBlocksize;
  UINT32          BLFilesize;
  CHAR8           OSVersion[40];
  CHAR8           AppVersion[40];
  CHAR8           CreationDate[10];
  CHAR8           CreationTime[10];
  CHAR8           SystemName[256]; // UTF-8
  CHAR8           TapeTitle[120]; // UTF-8
  CHAR8           pad[468]; // pad to 1024
} EFI_TAPE_HEADER;
```

13.7 Disk I/O Protocol

This section defines the Disk I/O protocol. This protocol is used to abstract the block accesses of the Block I/O protocol to a more general offset-length protocol. The firmware is responsible for adding this protocol to any Block I/O interface that appears in the system that does not already have a Disk I/O protocol. File systems and other disk access code utilize the Disk I/O protocol.

13.7.1 EFI_DISK_IO_PROTOCOL

Summary

This protocol is used to abstract Block I/O interfaces.

GUID

```
#define EFI_DISK_IO_PROTOCOL_GUID \
 {0xCE345171,0xBA0B,0x11d2,\
  {0x8e,0x4F,0x00,0xa0,0xc9,0x69,0x72,0x3b}}
```

Revision Number

```
#define EFI_DISK_IO_PROTOCOL_REVISION 0x00010000
```

Protocol Interface Structure

```
typedef struct _EFI_DISK_IO_PROTOCOL {
  UINT64                         Revision;
  EFI_DISK_READ                  ReadDisk;
  EFI_DISK_WRITE                 WriteDisk;
} EFI_DISK_IO_PROTOCOL;
```

Parameters

Revision
The revision to which the disk I/O interface adheres. All future revisions must be backwards compatible. If a future version is not backwards compatible, it is not the same GUID.

ReadDisk
Reads data from the disk. See the *EFI_DISK_IO_PROTOCOL.ReadDisk()* function description.

WriteDisk
Writes data to the disk. See the *EFI_DISK_IO_PROTOCOL.WriteDisk()* function description.

Description

The EFI_DISK_IO_PROTOCOL is used to control block I/O interfaces.

The disk I/O functions allow I/O operations that need not be on the underlying device's block boundaries or alignment requirements. This is done by copying the data to/from internal buffers as needed to provide the proper requests to the block I/O device. Outstanding write buffer data is flushed by using the *EFI_BLOCK_IO_PROTOCOL.FlushBlocks()* function of the *EFI_BLOCK_IO_PROTOCOL* on the device handle.

The firmware automatically adds an EFI_DISK_IO_PROTOCOL interface to any EFI_BLOCK_IO_PROTOCOL interface that is produced. It also adds file system, or logical block I/O, interfaces to any *EFI_DISK_IO_PROTOCOL* interface that contains any recognized file system or logical block I/O devices. The firmware must automatically support the following required formats:

- The EFI FAT12, FAT16, and FAT32 file system type.

- The legacy master boot record partition block. (The presence of this on any block I/O device is optional, but if it is present the firmware is responsible for allocating a logical device for each partition).
- The extended partition record partition block.
- The El Torito logical block devices.

13.7.2 EFI_DISK_IO_PROTOCOL.ReadDisk()

Summary

Reads a specified number of bytes from a device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_DISK_READ) (
        IN EFI_DISK_IO_PROTOCOL        *This,
  IN UINT32                          MediaId,
  IN UINT64                          Offset,
  IN UINTN                           BufferSize,
  OUT VOID                           *Buffer
   );
```

Parameters

This
Indicates a pointer to the calling context. Type EFI_DISK_IO_PROTOCOL is defined in the *EFI_DISK_IO_PROTOCOL* description.

MediaId
ID of the medium to be read.

Offset
The starting byte offset on the logical block I/O device to read from.

BufferSize
The size in bytes of Buffer. The number of bytes to read from the device.

Buffer
A pointer to the destination buffer for the data. The caller is responsible for either having implicit or explicit ownership of the buffer.

Description

The ReadDisk() function reads the number of bytes specified by BufferSize from the device. All the bytes are read, or an error is returned. If there is no medium in the device, the function returns EFI_NO_MEDIA. If the MediaId is not the ID of the medium currently in the device, the function returns EFI_MEDIA_CHANGED.

Status Codes Returned

EFI_SUCCESS	The data was read correctly from the device.
EFI_DEVICE_ERROR	The device reported an error while performing the read operation.
EFI_NO_MEDIA	There is no medium in the device.
EFI_MEDIA_CHANGED	The MediaId is not for the current medium.
EFI_INVALID_PARAMETER	The read request contains device addresses that are not valid for the device.

13.7.3 EFI_DISK_IO_PROTOCOL.WriteDisk()

Summary

Writes a specified number of bytes to a device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_DISK_WRITE) (
  IN EFI_DISK_IO_PROTOCOL    *This,
  IN UINT32                  MediaId,
  IN UINT64                  Offset,
  IN UINTN                   BufferSize,
  IN VOID                    *Buffer
  );
```

Parameters

This
Indicates a pointer to the calling context. Type EFI_DISK_IO_PROTOCOL is defined in the *EFI_DISK_IO_PROTOCOL* protocol description.

MediaId
ID of the medium to be written.

Offset
The starting byte offset on the logical block I/O device to write.

BufferSize
The size in bytes of Buffer. The number of bytes to write to the device.

Buffer
A pointer to the buffer containing the data to be written.

Description

The WriteDisk() function writes the number of bytes specified by BufferSize to the device. All bytes are written, or an error is returned. If there is no medium in the device, the function returns EFI_NO_MEDIA. If the MediaId is not the ID of the medium currently in the device, the function returns EFI_MEDIA_CHANGED.

Status Codes Returned

EFI_SUCCESS	The data was written correctly to the device.
EFI_WRITE_PROTECTED	The device cannot be written to.
EFI_NO_MEDIA	There is no medium in the device.
EFI_MEDIA_CHANGED	The MediaId is not for the current medium.
EFI_DEVICE_ERROR	The device reported an error while performing the write operation.
EFI_INVALID_PARAMETER	The write request contains device addresses that are not valid for the device.

13.8 Disk I/O 2 Protocol

The Disk I/O 2 protocol defines an extension to the Disk I/O protocol to enable non-blocking / asynchronous byte-oriented disk operation.

13.8.1 EFI_DISK_IO2_PROTOCOL

Summary

This protocol is used to abstract Block I/O interfaces in a non-blocking manner.

GUID

```
#define EFI_DISK_IO2_PROTOCOL_GUID \
 { 0x151c8eae, 0x7f2c, 0x472c, \
  {0x9e, 0x54, 0x98, 0x28, 0x19, 0x4f, 0x6a, 0x88 }}
```

Revision Number

```
#define EFI_DISK_IO2_PROTOCOL_REVISION 0x00020000
```

Protocol Interface Structure

```
typedef struct _EFI_DISK_IO2_PROTOCOL {
  UINT64                              Revision;
  EFI_DISK_CANCEL_EX                  Cancel;
  EFI_DISK_READ_EX                    ReadDiskEx;
  EFI_DISK_WRITE_EX                   WriteDiskEx;
  EFI_DISK_FLUSH_EX                   FlushDiskEx;
} EFI_DISK_IO2_PROTOCOL;
```

Parameters

Revision
The revision to which the disk I/O interface adheres. All future revisions must be backwards compatible.

Cancel
Terminate outstanding requests. See the *Cancel()* function description.

ReadDiskEx
Reads data from the disk. See the *ReadDiskEx()* function description.

WriteDiskEx
Writes data to the disk. See the *WriteDiskEx()* function description.

FlushDiskEx
Flushes all modified data to the physical device. See the *FlushDiskEx()* function description.

Description

The *EFI_DISK_IO2_PROTOCOL* is used to control block I/O interfaces.

The disk I/O functions allow I/O operations that need not be on the underlying device's block boundaries or alignment requirements. This is done by copying the data to/from internal buffers as needed to provide the proper requests to the block I/O device. Outstanding write buffer data is flushed by using the *FlushBlocksEx()* function of the *EFI_BLOCK_IO2_PROTOCOL* on the device handle.

The firmware automatically adds an *EFI_DISK_IO2_PROTOCOL* interface to any *EFI_BLOCK_IO2_PROTOCOL* interface that is produced. It also adds file system, or logical block I/O, interfaces to any *EFI_DISK_IO2_PROTOCOL* interface that contains any recognized file system or logical block I/O devices.

Implementations must account for cases where there is pending queued asynchronous I/O when a call is received on a blocking protocol interface. In these cases the pending I/O will be processed and completed before the blocking function is executed so that operation are carried out in the order they were requested.

13.8.2 EFI_DISK_IO2_PROTOCOL.Cancel()

Summary

Terminate outstanding asynchronous requests to a device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_DISK_CANCEL_EX) (
  IN EFI_DISK_IO2_PROTOCOL      *This
  );
```

Parameters

This

Indicates a pointer to the calling context. Type *EFI_DISK_IO2_PROTOCOL* is defined in the *EFI_DISK_IO2_PROTOCOL* description.

Description

The *Cancel()* function will terminate any in-flight non-blocking I/O requests by signaling the *EFI_DISK_IO2_TOKEN* Event and with *TransactionStatus* set to EFI_ABORTED. After the *Cancel()* function returns it is safe to free any *Token* or *Buffer* data structures that were allocated as part of the non-blocking I/O operation.

Status Codes Returned

EFI_SUCCESS	All outstanding requests were successfully terminated.
EFI_DEVICE_ERROR	The device reported an error while performing the cancel operation.

13.8.3 EFI_DISK_IO2_PROTOCOL.ReadDiskEx()

Summary

Reads a specified number of bytes from a device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_DISK_READ_EX) (
  IN EFI_DISK_IO2_PROTOCOL      *This,
  IN UINT32                     MediaId,
  IN UINT64                     Offset,
```

(continues on next page)

(continued from previous page)

```
  IN OUT EFI_DISK_IO2_TOKEN      *Token,
  IN UINTN                       BufferSize,
  OUT VOID                       *Buffer
  );
```

Parameters

This

Indicates a pointer to the calling context. Type *EFI_DISK_IO2_PROTOCOL* is defined in the *EFI_DISK_IO2_PROTOCOL* description.

MediaId

ID of the medium to be read.

Offset

The starting byte offset on the logical block I/O device to read from.

Token

A pointer to the token associated with the transaction. Type *EFI_DISK_IO2_TOKEN* is defined in "Related Definitions" below. If this field is NULL, synchronous/blocking IO is performed.

BufferSize

The size in bytes of *Buffer*. The number of bytes to read from the device.

Buffer

A pointer to the destination buffer for the data. The caller is responsible either having implicit or explicit ownership of the buffer.

Description

The *ReadDiskEx()* function reads the number of bytes specified by *BufferSize* from the device. All the bytes are read, or an error is returned. If there is no medium in the device, the function returns *EFI_NO_MEDIA*. If the *MediaId* is not the ID of the medium currently in the device, the function returns *EFI_MEDIA_CHANGED*.

If an error is returned from the call to *ReadDiskEx()* and non-blocking I/O is being requested, the *Event* associated with this request will not be signaled. If the call to *ReadDiskEx()* succeeds then the *Event* will be signaled upon completion of the read or if an error occurs during the processing of the request. The status of the read request can be determined from the *Status* field of the *Token* once the event is signaled.

Related Definitions

```
typedef struct {
  EFI_EVENT                Event;
  EFI_STATUS               TransactionStatus;
  } EFI_DISK_IO2_TOKEN;
```

Event

If *Event* is **NULL**, then blocking I/O is performed. If Event is not **NULL** and non-blocking I/O is supported, then non-blocking I/O is performed, and *Event* will be signaled when the I/O request is completed. The caller must be prepared to handle the case where the callback associated with *Event* occurs before the original asynchronous I/O request call returns.

TransactionStatus

Defines whether or not the signaled event encountered an error.

Status Codes Returned

EFI_SUCCESS	Returned from the call *ReadDiskEx()* If Event is **NULL** (blocking I/O): The data was read correctly from the device. If Event is not **NULL** (asynchronous I/O): The request was successfully queued for processing. Event will be signaled upon completion. Returned in the token after signaling Event The data was read correctly from the device.
EFI_DEVICE_ERROR	The device reported an error while performing the read operation.
EFI_NO_MEDIA	There is no medium in the device.
EFI_MEDIA_CHANGED	The MediaId is not for the current medium.
EFI_INVALID_PARAMETER	The read request contains device addresses that are not valid for the device.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources

13.8.4 EFI_DISK_IO2_PROTOCOL.WriteDiskEx()

Summary

Writes a specified number of bytes to a device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_DISK_WRITE_EX) (
  IN EFI_DISK_IO2_PROTOCOL          *This,
  IN UINT32                         MediaId,
  IN UINT64                         Offset,
  IN OUT EFI_DISK_IO2_TOKEN         *Token,
  IN UINTN                          BufferSize,
  IN VOID                           *Buffer
  );
```

Parameters

This

Indicates a pointer to the calling context. Type *EFI_DISK_IO2_PROTOCOL* is defined in the *EFI_DISK_IO2_PROTOCOL* description.

MediaId

ID of the medium to be written.

Offset

The starting byte offset on the logical block I/O device to write to.

Token

A pointer to the token associated with the transaction. Type *EFI_DISK_IO2_TOKEN* is defined in “Related Definitions” below. If this field is NULL, synchronous/blocking IO is performed.

BufferSize

The size in bytes of *Buffer*. The number of bytes to write to the device.

Buffer

A pointer to the source buffer for the data. The caller is responsible.

Description

The *WriteDiskEx()* function writes the number of bytes specified by *BufferSize* to the device. All bytes are written, or an error is returned. If there is no medium in the device, the function returns *EFI_NO_MEDIA*. If the *MediaId* is not the ID of the medium currently in the device, the function returns *EFI_MEDIA_CHANGED*.

If an error is returned from the call to *WriteDiskEx()* and non-blocking I/O is being requested, the *Event* associated with this request will not be signaled. If the call to *WriteDiskEx()* succeeds then the *Event* will be signaled upon completion of the write or if an error occurs during the processing of the request. The status of the write request can be determined from the *Status* field of the *Token* once the event is signaled.

Status Codes Returned

EFI_SUCCESS	Returned from the call *WriteDiskEx()* If *Event* is NULL (blocking I/O): • The data was written correctly to the device. If Event is not NULL (asynchronous I/O): • The request was successfully queued for processing. Event will be signaled upon completion. Returned in the token after signaling Event • The data was written correctly to the device.
EFI_WRITE_PROTECTED	The device cannot be written to.
EFI_DEVICE_ERROR	The device reported an error while performing the write operation.
EFI_NO_MEDIA	There is no medium in the device.
EFI_MEDIA_CHANGED	The *MediaId* is not for the current medium.
EFI_INVALID_PARAMETER	The read request contains device addresses that are not valid for the device.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources

13.8.5 EFI_DISK_IO2_PROTOCOL.FlushDiskEx()

Summary

Flushes all modified data to the physical device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_DISK_FLUSH_EX) (
  IN EFI_DISK_IO2_PROTOCOL          *This,
  IN OUT EFI_DISK_IO2_TOKEN         *Token
  );
```

Parameters

This

Indicates a pointer to the calling context. Type *EFI_DISK_IO2_PROTOCOL* is defined in the *EFI_DISK_IO2_PROTOCOL* description.

Token

A pointer to the token associated with the transaction. Type *EFI_DISK_IO2_TOKEN* is defined in "Related Definitions" below. If this field is **NULL**, synchronous/blocking IO is performed.

Description

The *FlushDiskEx()* function flushes all modified data to the physical device. If an error is returned from the call to *FlushDiskEx()* and non-blocking I/O is being requested, the Event associated with this request will not be signaled. If the call to *FlushDiskEx()* succeeds then the *Event* will be signaled upon completion of the flush or if an error occurs during the processing of the request. The status of the flush request can be determined from the *Status* field of the *Token* once the event is signaled.

Status Codes Returned

EFI_SUCCESS	Returned from the call FlushDiskEx() If Event is NULL (blocking I/O): •The data was flushed successfully to the device. If Event is not NULL (asynchronous I/O): •The request was successfully queued for processing. Event will be signaled upon completion. Returned in the token after signaling Event The data was flushed successfully to the device.
EFI_WRITE_PROTECTED	The device cannot be written to.
EFI_DEVICE_ERROR	The device reported an error while performing the flush operation.
EFI_NO_MEDIA	There is no medium in the device.
EFI_MEDIA_CHANGED	The medium in the device has changed since the last access.
EFI_INVALID_PARAMETER	Token is NULL.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources

13.9 Block I/O Protocol

This section defines the Block I/O protocol. This protocol is used to abstract mass storage devices to allow code running in the EFI boot services environment to access them without specific knowledge of the type of device or controller that manages the device. Functions are defined to read and write data at a block level from mass storage devices as well as to manage such devices in the EFI boot services environment.

13.9.1 EFI_BLOCK_IO_PROTOCOL

Summary

This protocol provides control over block devices.

GUID

```
#define EFI_BLOCK_IO_PROTOCOL_GUID \
 {0x964e5b21,0x6459,0x11d2,\
  {0x8e,0x39,0x00,0xa0,0xc9,0x69,0x72,0x3b}}
```

Revision Number

```
#define EFI_BLOCK_IO_PROTOCOL_REVISION2   0x00020001
#define EFI_BLOCK_IO_PROTOCOL_REVISION3   ((2<<16) | (31))
```

Protocol Interface Structure

```
typedef struct _EFI_BLOCK_IO_PROTOCOL {
  UINT64                         Revision;
  EFI_BLOCK_IO_MEDIA             *Media;
  EFI_BLOCK_RESET                Reset;
  EFI_BLOCK_READ                 ReadBlocks;
  EFI_BLOCK_WRITE                WriteBlocks;
  EFI_BLOCK_FLUSH                FlushBlocks;
} EFI _BLOCK_IO_PROTOCOL;
```

Parameters

Revision
The revision to which the block IO interface adheres. All future revisions must be backwards compatible. If a future version is not back wards compatible it is not the same GUID.

Media
A pointer to the EFI_BLOCK_IO_MEDIA data for this device. Type EFI_BLOCK_IO_MEDIA is defined in "Related Definitions" below.

Reset
Resets the block device hardware. See the *EFI_BLOCK_IO_PROTOCOL.Reset()* function description.

ReadBlocks
Reads the requested number of blocks from the device. See the *EFI_BLOCK_IO_PROTOCOL.ReadBlocks()* function description.

WriteBlocks
Writes the requested number of blocks to the device. See the *EFI_BLOCK_IO_PROTOCOL.WriteBlocks()* function description.

FlushBlocks
Flushes any cache blocks. This function is optional and only needs to be supported on block devices that cache writes. See the *EFI_BLOCK_IO_PROTOCOL.FlushBlocks()* function description.

Related Definitions

```
//*******************************************************
// EFI_BLOCK_IO_MEDIA
//*******************************************************

typedef struct {
  UINT32                    MediaId;
  BOOLEAN                   RemovableMedia;
  BOOLEAN                   MediaPresent;
  BOOLEAN                   LogicalPartition;
  BOOLEAN                   ReadOnly;
  BOOLEAN                   WriteCaching;

  UINT32                    IoAlign;
  EFI_LBA                   LastBlock;
```

(continues on next page)

(continued from previous page)

```
   EFI_LBA                 LowestAlignedLba; //added in Revision 2
   UINT32                  LogicalBlocksPerPhysicalBlock;
//added in Revision 2
UINT32 OptimalTransferLengthGranularity;
// added in Revision 3
} EFI_BLOCK_IO_MEDIA;

//*******************************************************
// EFI_LBA
//*******************************************************
typedef UINT64 EFI_LBA;
```

The following data values in EFI_BLOCK_IO_MEDIA are read-only and are updated by the code that produces the EFI_BLOCK_IO_PROTOCOL functions:

MediaId
The current media ID. If the media changes, this value is changed.

RemovableMedia
TRUE if the media is removable; otherwise, **FALSE**.

MediaPresent
TRUE if there is a media currently present in the device; otherwise, **FALSE**. This field shows the media present status as of the most recent *EFI_BLOCK_IO_PROTOCOL.ReadBlocks()* or WriteBlocks() call.

LogicalPartition
TRUE if the EFI_BLOCK_IO_PROTOCOL was produced to abstract partition structures on the disk. **FALSE** if the BLOCK_IO protocol was produced to abstract the logical blocks on a hardware device.

ReadOnly
TRUE if the media is marked read-only otherwise, **FALSE**. This field shows the read-only status as of the most recent *EFI_BLOCK_IO_PROTOCOL.WriteBlocks()* call.

WriteCaching
TRUE if the WriteBlocks() function caches write data.

BlockSize
The intrinsic block size of the device. If the media changes, then this field is updated.Returns the number of bytes per logical block. For ATA devices, this is reported in IDENTIFY DEVICE data words 117-118 (i.e., Words per Logical Sector) (see ATA8-ACS). For SCSI devices, this is reported in the READ CAPACITY (16) parameter data Logical Block Length In Bytes field (see SBC-3).

IoAlign
Supplies the alignment requirement for any buffer used in a data transfer. IoAlign values of 0 and 1 mean that the buffer can be placed anywhere in memory. Otherwise, IoAlign must be a power of 2, and the requirement is that the start address of a buffer must be evenly divisible by IoAlign with no remainder.

LastBlock
The last LBA on the device. If the media changes, then this field is updated. For ATA devices, this is reported in IDENTIFY DEVICE data words 60-61 (i.e., Total number of user addressable logical sectors) (see ATA8-ACS) minus one. For SCSI devices, this is reported in the READ CAPACITY (16) parameter data Returned Logical Block Address field (see SBC-3) minus one.

LowestAlignedLba
Only present if *EFI_BLOCK_IO_PROTOCOL. Revision* is greater than or equal to *EFI_BLOCK_IO_PROTOCOL_REVISION2*. Returns the first LBA that is aligned to a physical block

boundary (See *GPT overview*). Note that this field follows the SCSI definition, not the ATA definition. If *LogicalPartition* is *TRUE* this value will be zero.

LogicalBlocksPerPhysicalBlock
Only present if *EFI_BLOCK_IO_PROTOCOL. Revision* is greater than or equal to *EFI_BLOCK_IO_PROTOCOL_REVISION2*. Returns the number of logical blocks per physical block (See *GPT overview*) . Unlike the ATA and SCSI fields that provide the information for this field, this field does not contain an exponential value. A value of 0 means there is either one logical block per physical block, or there are more than one physical block per logical block. If *LogicalPartition* is *TRUE* this value will be zero.

OptimalTransferLengthGranularity
Only present if *EFI_BLOCK_IO_PROTOCOL*.Revision is greater than or equal to *EFI_BLOCK_IO_PROTOCOL_REVISION3*. Returns the optimal transfer length granularity as a number of logical blocks (See *GPT overview*). A value of 0 means there is no reported optimal transfer length granularity. If *LogicalPartition* is *TRUE* this value will be zero.

Description

The LogicalPartition is **TRUE** if the device handle is for a partition. For media that have only one partition, the value will always be **TRUE**. For media that have multiple partitions, this value is **FALSE** for the handle that accesses the entire device. The firmware is responsible for adding device handles for each partition on such media.

The firmware is responsible for adding an *EFI_DISK_IO_PROTOCOL* interface to every *EFI_BLOCK_IO_PROTOCOL* interface in the system. The EFI_DISK_IO_PROTOCOL interface allows byte-level access to devices.

13.9.2 EFI_BLOCK_IO_PROTOCOL.Reset()

Summary

Resets the block device hardware.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_BLOCK_RESET) (
  IN EFI_BLOCK_IO_PROTOCOL    *This,
  IN BOOLEAN                  ExtendedVerification
  );
```

Parameters

This
Indicates a pointer to the calling context. Type EFI_BLOCK_IO_PROTOCOL is defined in the *EFI_BLOCK_IO_PROTOCOL* description.

ExtendedVerification
Indicates that the driver may perform a more exhaustive verification operation of the device during reset.

Description

The Reset() function resets the block device hardware.

As part of the initialization process, the firmware/device will make a quick but reasonable attempt to verify that the device is functioning. If the ExtendedVerification flag is **TRUE** the firmware may take an extended amount of time to verify the device is operating on reset. Otherwise the reset operation is to occur as quickly as possible.

The hardware verification process is not defined by this specification and is left up to the platform firmware or driver to implement.

EFI_SUCCESS	The block device was reset.
EFI_DEVICE_ERROR	The block device is not functioning correctly and could not be reset.

13.9.3 EFI_BLOCK_IO_PROTOCOL.ReadBlocks()

Summary

Reads the requested number of blocks from the device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_BLOCK_READ) (
  IN EFI_BLOCK_IO_PROTOCOL    *This,
  IN UINT32                   MediaId,
  IN EFI_LBA                  LBA,
  IN UINTN                    BufferSize,
  OUT VOID                    *Buffer
  );
```

Parameters

This
Indicates a pointer to the calling context. Type EFI_BLOCK_IO_PROTOCOL is defined in the *EFI_BLOCK_IO_PROTOCOL* description.

MediaId
The media ID that the read request is for.

LBA
The starting logical block address to read from on the device. Type EFI_LBA is defined in the *EFI_BLOCK_IO_PROTOCOL* description.

BufferSize
The size of the Buffer in bytes. This must be a multiple of the intrinsic block size of the device.

Buffer
A pointer to the destination buffer for the data. The caller is responsible for either having implicit or explicit ownership of the buffer.

Description

The ReadBlocks() function reads the requested number of blocks from the device. All the blocks are read, or an error is returned.

If there is no media in the device, the function returns EFI_NO_MEDIA. If the MediaId is not the ID for the current media in the device, the function returns EFI_MEDIA_CHANGED. The function must return *EFI_NO_MEDIA* or *EFI_MEDIA_CHANGED* even if *LBA, BufferSize,* or *Buffer* are invalid so the caller can probe for changes in media state.

Status Codes Returned

EFI_SUCCESS	The data was read correctly from the device.
EFI_DEVICE_ERROR	The device reported an error while attempting to perform the read operation.
EFI_NO_MEDIA	There is no media in the device.

continues on next page

Table 13.31 – continued from previous page

EFI_MEDIA_CHANGED	The MediaId is not for the current media.
EFI_BAD_BUFFER_SIZE	The BufferSize parameter is not a multiple of the intrinsic block size of the device.
EFI_INVALID_PARAMETER	The read request contains LBAs that are not valid, or the buffer is not on proper alignment.

13.9.4 EFI_BLOCK_IO_PROTOCOL.WriteBlocks()

Summary

Writes a specified number of blocks to the device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_BLOCK_WRITE) (
  IN EFI_BLOCK_IO_PROTOCOL       *This,
  IN UINT32                      MediaId,
  IN EFI_LBA                     LBA,
  IN UINTN                       BufferSize,
  IN VOID                        *Buffer
  );
```

Parameters

This
Indicates a pointer to the calling context. Type is defined in the See *EFI_BLOCK_IO_PROTOCOL* description.

MediaId
The media ID that the write request is for.

LBA
The starting logical block address to be written. The caller is responsible for writing to only legitimate locations. Type EFI_LBA is defined in the *EFI_BLOCK_IO_PROTOCOL* description.

BufferSize
The size in bytes of Buffer. This must be a multiple of the intrinsic block size of the device.

Buffer
A pointer to the source buffer for the data.

Description

The WriteBlocks() function writes the requested number of blocks to the device. All blocks are written, or an error is returned.

If there is no media in the device, the function returns EFI_NO_MEDIA. If the MediaId is not the ID for the current media in the device, the function returns EFI_MEDIA_CHANGED. The function must return *EFI_NO_MEDIA* or *EFI_MEDIA_CHANGED* even if *LBA, BufferSize,* or *Buffer* are invalid so the caller can probe for changes in media state.

Status Codes Returned

EFI_SUCCESS	The data were written correctly to the device.
EFI_WRITE_PROTECTED	The device cannot be written to.

continues on next page

Table 13.32 – continued from previous page

EFI_NO_MEDIA	There is no media in the device.
EFI_MEDIA_CHANGED	The MediaId is not for the current media.
EFI_DEVICE_ERROR	The device reported an error while attempting to perform the write operation.
EFI_BAD_BUFFER_SIZE	The BufferSize parameter is not a multiple of the intrinsic block size of the device.
EFI_INVALID_PARAMETER	The write request contains LBAs that are not valid, or the buffer is not on proper alignment.

13.9.5 EFI_BLOCK_IO_PROTOCOL.FlushBlocks()

Summary

Flushes all modified data to a physical block device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_BLOCK_FLUSH) (
  IN EFI_BLOCK_IO_PROTOCOL    *This
  );
```

Parameters

This

Indicates a pointer to the calling context. Type EFI_BLOCK_IO_PROTOCOL is defined in the *EFI_BLOCK_IO_PROTOCOL* protocol description.

Description

The FlushBlocks() function flushes all modified data to the physical block device.

All data written to the device prior to the flush must be physically written before returning EFI_SUCCESS from this function. This would include any cached data the driver may have cached, and cached data the device may have cached. A flush may cause a read request following the flush to force a device access.

Status Codes Returned

EFI_SUCCESS	All outstanding data were written correctly to the device.
EFI_DEVICE_ERROR	The device reported an error while attempting to write data.
EFI_NO_MEDIA	There is no media in the device.

13.10 Block I/O 2 Protocol

The Block I/O 2 protocol defines an extension to the Block I/O protocol which enables the ability to read and write data at a block level in a non-blocking manner.

13.10.1 EFI_BLOCK_IO2_PROTOCOL

Summary

This protocol provides control over block devices.

GUID

```
#define EFI_BLOCK_IO2_PROTOCOL_GUID \
 {0xa77b2472, 0xe282, 0x4e9f, \
  {0xa2, 0x45, 0xc2, 0xc0, 0xe2, 0x7b, 0xbc, 0xc1}}
```

Protocol Interface Structure

```
typedef struct _EFI_BLOCK_IO2_PROTOCOL {
  EFI_BLOCK_IO_MEDIA       *Media;
  EFI_BLOCK_RESET_EX       Reset;
  EFI_BLOCK_READ_EX        ReadBlocksEx;
  EFI_BLOCK_WRITE_EX       WriteBlocksEx;
  EFI_BLOCK_FLUSH_EX       FlushBlocksEx;
}  EFI_BLOCK_IO2_PROTOCOL;
```

Parameters

Media
A pointer to the *EFI_BLOCK_IO_MEDIA* data for this device. Type *EFI_BLOCK_IO_MEDIA* is defined in the *EFI_BLOCK_IO_PROTOCOL* section.

Reset
Resets the block device hardware. See the *EFI_BLOCK_IO_PROTOCOL.Reset()* function description following below.

ReadBlocksEx
Reads the requested number of blocks from the device. See the *EFI_BLOCK_IO2_PROTOCOL* function description.

WriteBlocksEx
Writes the requested number of blocks to the device. See the *EFI_BLOCK_IO2_PROTOCOL.WriteBlocksEx()* function description.

FlushBlocksEx
Flushes any cache blocks. This function is optional and only needs to be supported on block devices that cache writes. See the *EFI_BLOCK_IO2_PROTOCOL.FlushBlocksEx()* function description.

13.10.2 EFI_BLOCK_IO2_PROTOCOL.Reset()

Summary

Resets the block device hardware.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_BLOCK_RESET_EX) (
  IN EFI_BLOCK_IO2_PROTOCOL   *This,
  IN BOOLEAN                  ExtendedVerification
  );
```

Parameters

This

Indicates a pointer to the calling context. Type *EFI_BLOCK_IO2_PROTOCOL* is defined in the *EFI_BLOCK_IO2_PROTOCOL* description.

ExtendedVerification

Indicates that the driver may perform a more exhaustive verification operation of the device during reset.

Description

The *Reset()* function resets the block device hardware.

As part of the initialization process, the firmware/device will make a quick but reasonable attempt to verify that the device is functioning. If the *ExtendedVerification* flag is **TRUE** the firmware may take an extended amount of time to verify the device is operating on reset. Otherwise the reset operation is to occur as quickly as possible.

The hardware verification process is not defined by this specification and is left up to the platform firmware or driver to implement.

The *Reset()* function will terminate any in-flight non-blocking I/O requests by signaling an *EFI_ABORTED* in the *TransactionStatus* member of the *EFI_BLOCK_IO2_TOKEN* for the non-blocking I/O. After the *Reset()* function returns it is safe to free any *Token* or *Buffer* data structures that were allocated to initiate the non-blocking I/O requests that were in-flight for this device.

Status Codes Returned

EFI_SUCCESS	The block device was reset.
EFI_DEVICE_ERROR	The block device is not functioning correctly and could not be reset.

13.10.3 EFI_BLOCK_IO2_PROTOCOL.ReadBlocksEx()

Summary

Reads the requested number of blocks from the device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_BLOCK_READ_EX) (
  IN EFI_BLOCK_IO2_PROTOCOL      *This,
  IN UINT32                      MediaId,
  IN EFI_LBA                     LBA,
  IN OUT EFI_BLOCK_IO2_TOKEN     *Token,
  IN UINTN                       BufferSize,
  OUT VOID                       *Buffer
  );
```

Parameters

This

Indicates a pointer to the calling context. Type *EFI_BLOCK_IO2_PROTOCOL* is defined in the *EFI_BLOCK_IO2_PROTOCOL* description.

MediaId

The media ID that the read request is for.

LBA

The starting logical block address to read from on the device. Type *EFI_LBA* is defined in the *EFI_BLOCK_IO_PROTOCOL* description.

Token

A pointer to the token associated with the transaction. Type *EFI_BLOCK_IO2_TOKEN* is defined in "Related Definitions" below.

BufferSize

The size of the *Buffer* in bytes. This must be a multiple of the intrinsic block size of the device.

Buffer

A pointer to the destination buffer for the data. The caller is responsible for either having implicit or explicit ownership of the buffer.

Description

The *ReadBlocksEx()* function reads the requested number of blocks from the device. All the blocks are read, or an error is returned.

If there is no media in the device, the function returns EFI_NO_MEDIA. If the MediaId is not the ID for the current media in the device, the function returns EFI_MEDIA_CHANGED. The function must return *EFI_NO_MEDIA* or *EFI_MEDIA_CHANGED* even if *LBA, BufferSize,* or *Buffer* are invalid so the caller can probe for changes in media state.

If *EFI_DEVICE_ERROR, EFI_NO_MEDIA,*_or *EFI_MEDIA_CHANGED* is returned and non-blocking I/O is being used, the *Event* associated with this request will not be signaled.

Related Definitions

```
typedef struct {
  EFI_EVENT          Event;
  EFI_STATUS         TransactionStatus;
} EFI_BLOCK_IO2_TOKEN;
```

Event

If *Event* is **NULL**, then blocking I/O is performed. If *Event* is not **NULL** and non-blocking I/O is supported, then non-blocking I/O is performed, and *Event* will be signaled when the read request is completed.

TransactionStatus

Defines whether the signaled event encountered an error.

Status Codes Returned

EFI_SUCCESS	The read request was queued if Token-> Event is not **NULL**. The data was read correctly from the device if theToken-> Event is **NULL**.
EFI_DEVICE_ERROR	The device reported an error while attempting to perform the read operation.
EFI_NO_MEDIA	There is no media in the device.
EFI_MEDIA_CHANGED	The *MediaId* is not for the current media.
EFI_BAD_BUFFER_SIZE	The *BufferSize* parameter is not a multiple of the intrinsic block size of the device.
EFI_INVALID_PARAMETER	The read request contains LBAs that are not valid, or the buffer is not on proper alignment.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources

---

13.10.4 EFI_BLOCK_IO2_PROTOCOL.WriteBlocksEx()

Summary

Writes a specified number of blocks to the device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_BLOCK_WRITE_EX) (
  IN EFI_BLOCK_IO2_PROTOCOL   *This,
  IN UINT32                   MediaId,
  IN EFI_LBA                  LBA,
  IN OUT EFI_BLOCK_IO2_TOKEN  *Token,
  IN UINTN                    BufferSize,
  IN VOID                     *Buffer
  );
```

Parameters

This

Indicates a pointer to the calling context. Type *EFI_BLOCK_IO2_PROTOCOL* is defined in the *EFI_BLOCK_IO2_PROTOCOL* description.

MediaId

The media ID that the write request is for.

LBA

The starting logical block address to be written. The caller is responsible for writing to only legitimate locations. Type *EFI_LBA* is defined in the *EFI_BLOCK_IO2_PROTOCOL* description.

Token

A pointer to the token associated with the transaction. Type EFI_BLOCK_IO2_TOKEN is defined in *EFI_BLOCK_IO2_PROTOCOL.ReadBlocksEx()* "Related Definitions".

BufferSize

The size in bytes of *Buffer*. This must be a multiple of the intrinsic block size of the device.

Buffer

A pointer to the source buffer for the data.

Description

The WriteBlocksEx() function writes the requested number of blocks to the device. All blocks are written, or an error is returned.

If there is no media in the device, the function returns EFI_NO_MEDIA. If the MediaId is not the ID for the current media in the device, the function returns EFI_MEDIA_CHANGED. The function must return *EFI_NO_MEDIA* or *EFI_MEDIA_CHANGED* even if *LBA, BufferSize,* or *Buffer* are invalid so the caller can probe for changes in media state.

If *EFI_DEVICE_ERROR, EFI_NO_MEDIA,* * _EFI_WRITE_PROTECTED* or *EFI_MEDIA_CHANGED* is returned and non-blocking I/O is being used, the *Event* associated with this request will not be signaled.

Related Definitions

```
typedef struct {
  EFI_EVENT             Event;
  EFI_STATUS            TransactionStatus;
}  EFI_BLOCK_IO2_TOKEN;
```

Event

If *Event* is **NULL**, then blocking I/O is performed. If *Event* is not **NULL** and non-blocking I/O is supported, then non-blocking I/O is performed, and *Event* will be signaled when the write request is completed.

TransactionStatus

Defines whether the signaled event encountered an error.

Status Codes Returned

EFI_SUCCESS	The write request was queued if Event is not NULL. The data was written correctly to the device if the Event is NULL.
EFI_WRITE_PROTECTED	The device cannot be written to.
EFI_NO_MEDIA	There is no media in the device.
EFI_MEDIA_CHANGED	The *MediaId* is not for the current media.
EFI_DEVICE_ERROR	The device reported an error while attempting to perform the write operation.
EFI_BAD_BUFFER_SIZE	The *BufferSize* parameter is not a multiple of the intrinsic block size of the device.
EFI_INVALID_PARAMETER	The write request contains LBAs that are not valid, or the buffer is not on proper alignment.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources

13.10.5 EFI_BLOCK_IO2_PROTOCOL.FlushBlocksEx()

Summary

Flushes all modified data to a physical block device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_BLOCK_FLUSH_EX) (
  IN EFI_BLOCK_IO2_PROTOCOL         *This,
  IN OUT EFI_BLOCK_IO2_TOKEN        *Token,
  );
```

Parameters

This

Indicates a pointer to the calling context. Type *EFI_BLOCK_IO2_PROTOCOL* is defined in the *EFI_BLOCK_IO2_PROTOCOL* protocol description.

Token

A pointer to the token associated with the transaction. Type *EFI_BLOCK_IO2_TOKEN* is defined in *EFI_BLOCK_IO2_PROTOCOL.ReadBlocksEx()* “Related Definitions”.

Related Definitions

```
typedef struct {
  EFI_EVENT             Event;
  EFI_STATUS            TransactionStatus;
}  EFI_BLOCK_IO2_TOKEN;
```

Event

If *Event* is **NULL**, then blocking I/O is performed. If *Event* is not **NULL** and non-blocking I/O is supported, then non-blocking I/O is performed, and *Event* will be signaled when the flush request is completed.

TransactionStatus

Defines whether the signaled event encountered an error.

Description

The *FlushBlocksEx()* function flushes all modified data to the physical block device.

All data written to the device prior to the flush must be physically written before returning *EFI_SUCCESS* from this function. This would include any cached data the driver may have cached, and cached data the device may have cached. A flush may cause a read request following the flush to force a device access.

If *EFI_DEVICE_ERROR, EFI_NO_MEDIA, EFI_WRITE_PROTECTED* or *EFI_MEDIA_CHANGED* is returned and non-blocking I/O is being used, the *Event* associated with this request will not be signaled.

Status Codes Returned

EFI_SUCCESS	The flush request was queued if Event is not **NULL**. All outstanding data was written correctly to the device if the Event is **NULL**.
EFI_DEVICE_ERROR	The device reported an error while attempting to write data.
EFI_WRITE_PROTECTED	The device cannot be written to.
EFI_NO_MEDIA	There is no media in the device.
EFI_MEDIA_CHANGED	The *MediaId* is not for the current media.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources

13.11 Inline Cryptographic Interface Protocol

13.11.1 EFI_BLOCK_IO_CRYPTO_PROTOCOL

Summary

The UEFI Inline Cryptographic Interface protocol provides services to abstract access to inline cryptographic capabilities.

The usage model of this protocol is similar to the one of the *EFI_STORAGE_SECURITY_COMMAND_PROTOCOL* where FDE (Full Disk Encryption) solutions leave ESP partition unprotected (unencrypted) allowing storage clients to continue using *EFI_BLOCK_IO_PROTOCOL* or *EFI_BLOCK_IO2_PROTOCOL* protocol interfaces to load OS boot components from ESP partition. For other partitions boot apps (including OS boot app) that are enlightened to take advantage of inline cryptographic capability will be empowered to use this new protocol.

GUID

```
#define EFI_BLOCK_IO_CRYPTO_PROTOCOL_GUID \
 {0xa00490ba,0x3f1a,0x4b4c,\
  {0xab,0x90,0x4f,0xa9,0x97,0x26,0xa1,0xe8}}
```

Protocol Interface Structure

```
typedef struct _EFI_BLOCK_IO_CRYPTO_PROTOCOL {
  EFI_BLOCK_IO_MEDIA                        *Media;
  EFI_BLOCK_IO_CRYPTO_RESET                 Reset;
  EFI_BLOCK_IO_CRYPTO_GET_CAPABILITIES      GetCapabilities;
  EFI_BLOCK_IO_CRYPTO_SET_CONFIGURATION     SetConfiguration;
  EFI_BLOCK_IO_CRYPTO_GET_CONFIGURATION     GetConfiguration;
  EFI_BLOCK_IO_CRYPTO_READ_DEVICE_EXTENDED  ReadExtended;
  EFI_BLOCK_IO_CRYPTO_WRITE_DEVICE_EXTENDED WriteExtended;
  EFI_BLOCK_IO_CRYPTO_FLUSH                 FlushBlocks;
} EFI_BLOCK_IO_CRYPTO_PROTOCOL;
```

Parameters

Media
A pointer to the *EFI_BLOCK_IO_MEDIA* data for this device. Type *EFI_BLOCK_IO_MEDIA* is defined in the *EFI_BLOCK_IO_PROTOCOL* section.

Reset
Reset the block device hardware.

GetCapabilities
Get the current capabilities of the ICI.

SetConfiguration
Set the configuration for the ICI instance.

GetConfiguration
Get the configuration for the ICI instance.

ReadExtended
Provide an extended version of the storage device read command.

WriteExtended
Provide an extended version of the storage device write command.

FlushBlocks
Flushes any cache blocks. This function is optional and only needs to be supported on block devices that cache writes.

Related Definitions

Some functions defined for this protocol require the caller to specify the device capabilities, keys and/or attributes of the keys to be used. These parameters must be consistent with the supported capabilities as reported by the device.

```
typedef struct {
  EFI_GUID        Algorithm;
  UINT64          KeySize;
  UINT64          CryptoBlockSizeBitMask;
} EFI_BLOCK_IO_CRYPTO_CAPABILITY;
```

Algorithm
GUID of the algorithm.

KeySize
Specifies *KeySize* in bits used with this Algorithm.

CryptoBlockSizeBitMask
Specifies bitmask of block sizes supported by this algorithm. Bit j being set means that 2^j bytes crypto block size is supported.

```
#define EFI_BLOCK_IO_CRYPTO_ALGO_GUID_AES_XTS \
 {0x2f87ba6a,\
  0x5c04,0x4385,0xa7,0x80,0xf3,0xbf,0x78,0xa9,0x7b,0xec}
```

EFI_BLOCK_IO_CRYPTO_ALGO_GUID_AES_XTS GUID represents Inline Cryptographic Interface capability supporting AES XTS crypto algorithm as described in IEEE Std 1619-2007: IEEE Standard for Cryptographic Protection of Data on Block-Oriented Storage Devices.

```
typedef struct {
  EFI_BLOCK_IO_CRYPTO_IV_INPUT    Header;
  UINT64                          CryptoBlockNumber;
  UINT64                          CryptoBlockByteSize;
} EFI_BLOCK_IO_CRYPTO_IV_INPUT_AES_XTS;
```

EFI_BLOCK_IO_CRYPTO_IV_INPUT_AES_XTS structure is used as CryptoIvInput parameter to the ReadExtended and WriteExtended methods for Inline Cryptographic Interface supporting and using AES XTS algorithm with IV input as defined for AES XTS algorithm. IO operation (read or write) range should consist of one or more blocks of *CryptoBlockByteSize* size. *CryptoBlockNumber* is used as the AES XTS IV for the first crypto block and is incremented by one for each consecutive crypto block in the IO operation range.

```
#define EFI_BLOCK_IO_CRYPTO_ALGO_GUID_AES_CBC_MICROSOFT_BITLOCKER \
{0x689e4c62,\
 0x70bf,0x4cf3,0x88,0xbb,0x33,0xb3,0x18,0x26,0x86,0x70}
```

EFI_BLOCK_IO_CRYPTO_ALGO_GUID_AES_CBC_MICROSOFT_BITLOCKER GUID represents Inline Cryptographic Interface capability supporting AES CBC crypto algorithm in the *non-diffuser* mode as described in following Microsoft white paper, section 4: See “Links to UEFI-Related Documents” (http://uefi.org/uefi) under the heading “Inline Cryptographic Interface–Bit Locker Cipher”. It is important to note that when excluding diffuser operations (A diffuser and B diffuser) described in the above document one should also exclude derivation of sector key and XOR-ing it with plaintext as that operation is part of the diffuser part of the algorithm and does not belong to the AES-CBC Microsoft BitLocker algorithm being referred to here.

```
typedef struct {
  EFI_BLOCK_IO_CRYPTO_IV_INPUT   Header;
  UINT64                         CryptoBlockByteOffset;
  UINT64                         CryptoBlockByteSize;
} EFI_BLOCK_IO_CRYPTO_IV_INPUT_AES_CBC_MICROSOFT_BITLOCKER;
```

EFI_BLOCK_IO_CRYPTO_IV_INPUT_AES_CBC_MICROSOFT_BITLOCKER structure is used to pass as CryptoIvInput parameter to the ReadExtended and WriteExtended methods for Inline Cryptographic Interface supporting and using AES CBC algorithm with IV input as defined for Microsoft BitLocker Drive Encryption. IO operation (read or write) range should consist of one or more blocks of *CryptoBlockByteSize* size. *CryptoBlockByteOffset* is used as the AES CBC Microsoft Bitlocker algorithm IV for the first crypto block and is incremented by *CryptoBlockByteSize* for each consecutive crypto block in the IO operation range.

```
typedef struct {
  UINT64                 InputSize;
}  EFI_BLOCK_IO_CRYPTO_IV_INPUT;
```

EFI_BLOCK_IO_CRYPTO_IV_INPUT structure is used as a common header in *CryptoIvInput* parameters passed to the ReadExtended and WriteExtended methods for Inline Cryptographic Interface. Its purpose is to pass size of the entire *CryptoIvInput* parameter memory buffer to the Inline Cryptographic Interface.

Further extensions of crypto algorithm support by Inline Cryptographic Interface should follow the same pattern established above for the AES XTS and AES CBC Microsoft BitLocker algorithms. In particular each added crypto algorithm should:

- Define its crypto algorithm GUID using following pattern:

```
#define EFI_BLOCK_IO_CRYPTO_ALGO_GUID_<algo-name> {<algo-guid>}
```

- Define its corresponding *CryptoIvInput* parameter structure and describe how it is populated for each IO operation (read / write):

```
typedef struct {
  EFI_BLOCK_IO_CRYPTO_IV_INPUT          Header;
  <TBD>                                 <TBD>;
}  EFI_BLOCK_IO_CRYPTO_IV_INPUT_<algo-name>;

#define EFI_BLOCK_IO_CRYPTO_INDEX_ANY  0xFFFFFFFFFFFFFFFF
typedef struct {
  BOOLEAN                             Supported;
  UINT64                              KeyCount;
  UINT64                              CapabilityCount;
  EFI_BLOCK_IO_CRYPTO_CAPABILITY    Capabilities [1];
} EFI_BLOCK_IO_CRYPTO_CAPABILITIES;
```

Supported
Is inline cryptographic capability supported on this device.

KeyCount
Maximum number of keys that can be configured at the same time.

CapabilityCount
Number of supported capabilities.

Capabilities
Array of supported capabilities.

```
typedef struct {
  UINT64                              Index;
  EFI_GUID                            KeyOwnerGuid;
  EFI_BLOCK_IO_CRYPTO_CAPABILITY     Capability;
  VOID                                *CryptoKey;
} EFI_BLOCK_IO_CRYPTO_CONFIGURATION_TABLE_ENTRY;
```

Index
Configuration table index. A special Index *EFI_BLOCK_IO_CRYPTO_INDEX_ANY* can be used to set any available entry in the configuration table.

KeyOwnerGuid
Identifies the owner of the configuration table entry. Entry can also be used with the Nil value to clear key from the configuration table index.

Capability
A supported capability to be used. The *CryptoBlockSizeBitMask* field of the structure should have only one bit set from the supported mask.

CryptoKey
Pointer to the key. The size of the key is defined by the *KeySize* field of the capability specified by the Capability parameter.

```
typedef struct {
  UINT64                           Index;
  EFI_GUID                         KeyOwnerGuid;
  EFI_BLOCK_IO_CRYPTO_CAPABILITY     Capability;
}  EFI_BLOCK_IO_CRYPTO_RESPONSE_CONFIGURATION_ENTRY;
```

Index
Configuration table index.

KeyOwnerGuid
Identifies the current owner of the entry.

Capability
The capability to be used. The *CryptoBlockSizeBitMask* field of the structure has only one bit set from the supported mask.

Description

The *EFI_BLOCK_IO_CRYPTO_PROTOCOL* defines a UEFI protocol that can be used by UEFI drivers and applications to perform block encryption on a storage device, such as UFS.

The *EFI_BLOCK_IO_CRYPTO_PROTOCOL* instance will be on the same handle as the device path of the inline encryption device.

While this protocol is intended to abstract the encryption process for block device access, the protocol user does not have to be aware of the specific underlying encryption hardware.

13.11.2 EFI_BLOCK_IO_CRYPTO_PROTOCOL.Reset()

Summary

Resets the block device hardware.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_BLOCK_IO_CRYPTO_RESET) (
IN EFI_BLOCK_IO_CRYPTO_PROTOCOL     *This,
IN BOOLEAN                          ExtendedVerification
);
```

Parameters

This
Pointer to the *EFI_BLOCK_IO_CRYPTO_PROTOCOL* instance.

ExtendedVerification
Indicates that the driver may perform a more exhaustive verification operation of the device during reset.

Description

The *Reset()* function resets the block device hardware.

As part of the initialization process, the firmware/device will make a quick but reasonable attempt to verify that the device is functioning. If the *ExtendedVerification* flag is **TRUE** the firmware may take an extended amount of time to verify the device is operating on reset. Otherwise the reset operation is to occur as quickly as possible.

The hardware verification process is not defined by this specification and is left up to the platform firmware or driver to implement.

Status Codes Returned

EFI_SUCCESS	The block device was reset.
EFI_DEVICE_ERROR	The block device is not functioning correctly and could not be reset.
EFI_INVALID_PARAMETER	*This* is **NULL**.

13.11.3 EFI_BLOCK_IO_CRYPTO_PROTOCOL.GetCapabilities()

Summary

Get the capabilities of the underlying inline cryptographic interface.

Prototype

```
typedef EFI_STATUS
(EFIAPI *EFI_BLOCK_IO_CRYPTO_GET_CAPABILITIES) (
  IN EFI_BLOCK_IO_CRYPTO_PROTOCOL         *This,
  OUT EFI_BLOCK_IO_CRYPTO_CAPABILITIES    *Capabilities
  );
```

Parameters

This
Pointer to the *EFI_BLOCK_IO_CRYPTO_PROTOCOL* instance.

Capabilities
Pointer to the *EFI_BLOCK_IO_CRYPTO_CAPABILITIES* structure.

Description

The GetCapabilities() function determines whether pre-OS controllable inline crypto is supported by the system for the current disk and, if so, returns the capabilities of the crypto engine.

The caller is responsible for providing the Capabilities structure with a sufficient number of entries. If the structure is too small, the *EFI_BUFFER_TOO_SMALL* error code is returned and the CapabilityCount field contains the number of entries needed to contain the capabilities.

Status Codes Returned

EFI_SUCCESS	The ICI is ready for use.
EFI_BUFFER_TOO_SMALL	The Capabilities structure was too small. The number of entries needed is returned in the CapabilityCount field of the structure.
EFI_NO_RESPONSE	No response was received from the ICI
EFI_DEVICE_ERROR	An error occurred when attempting to access the ICI
EFI_INVALID_PARAMETER	*This* is **NULL**.
EFI_INVALID_PARAMETER	Capabilities is **NULL**

13.11.4 EFI_BLOCK_IO_CRYPTO_PROTOCOL.SetConfiguration()

Summary

Set the configuration of the underlying inline cryptographic interface.

Prototype

```
typedef EFI_STATUS
(EFIAPI *EFI_BLOCK_IO_CRYPTO_SET_CONFIGURATION) (
  IN EFI_BLOCK_IO_CRYPTO_PROTOCOL                    *This,
  IN UINT64                                          ConfigurationCount,
  IN EFI_BLOCK_IO_CRYPTO_CONFIGURATION_TABLE_ENTRY   *ConfigurationTable,
  OUT EFI_BLOCK_IO_CRYPTO_RESPONSE_CONFIGURATION_ENTRY
  *ResultingTable  OPTIONAL
  );
```

Parameters

This
Pointer to the *EFI_BLOCK_IO_CRYPTO_PROTOCOL* instance.

ConfigurationCount
Number of entries being configured with this call.

ConfigurationTable
Pointer to a table used to populate the configuration table.

ResultingTable
Optional pointer to a table that receives the newly configured entries.

Description

The *SetConfiguration()* function allows the user to set the current configuration of the inline cryptographic interface and should be called before attempting any crypto operations.

This configures the configuration table entries with algorithms, key sizes and keys. Each configured entry can later be referred to by index at the time of storage transaction.

The configuration table index will refer to the combination of KeyOwnerGuid, Algorithm, and CryptoKey. KeyOwnerGuid identifies the component taking ownership of the entry. It helps components to identify their own entries, cooperate with other owner components, and avoid conflicts. This Guid identifier is there to help coordination between cooperating components and not a security or synchronization feature. The Nil GUID can be used by a component to release use of entry owned. It is also used to identify potentially available entries (see GetConfiguration).

CryptoKey specifies algorithm-specific key material to use within parameters of selected crypto capability.

> This function is called infrequently - typically once, on device start, before IO starts. It can be called at later times in cases the number of keys used on the drive is higher than what can be configured at a time or a new key has to be added.
>
> Components setting or changing an entry or entries for a given index or indices must ensure that IO referencing affected indices is temporarily blocked (run-down) at the time of change.
>
> Indices parameters in each parameter table entry allow to set only a portion of the available table entries in the crypto module anywhere from single entry to entire table supported.
>
> If corresponding table entry or entries being set are already in use by another owner the call should be failed and none of the entries should be modified. The interface implementation must enforce atomicity of this

operation (should either succeed fully or fail completely without modifying state). Note that components using GetConfiguration command to discover available entries should be prepared that by the time of calling SetConfiguration the previously available entry may have become occupied. Such components should be prepared to re-try the sequence of operations. Alternatively *EFI_BLOCK_IO_CRYPTO_INDEX_ANY* can be used to have the implementation discover and allocate available, if any, indices atomically.

An optional ResultingTable pointer can be provided by the caller to receive the newly configured entries. The array provided by the caller must have at least ConfigurationCount of entries.

Status Codes Returned

EFI_SUCCESS	The ICI is ready for use.
EFI_NO_RESPONSE	No response was received from the ICI
EFI_DEVICE_ERROR	An error occurred when attempting to access the ICI
EFI_INVALID_PARAMETER	This is **NULL**.
EFI_INVALID_PARAMETER	*ConfigurationTable* is **NULL**
EFI_INVALID_PARAMETER	*ConfigurationCount* is 0
EFI_OUT_OF_RESOURCES	Could not find the requested number of available entries in the configuration table.

13.11.5 EFI_BLOCK_IO_CRYPTO_PROTOCOL.GetConfiguration()

Summary

Get the configuration of the underlying inline cryptographic interface.

Prototype

```
typedef EFI_STATUS
(EFIAPI *EFI_BLOCK_IO_CRYPTO_GET_CONFIGURATION) (
  IN EFI_BLOCK_IO_CRYPTO_PROTOCOL            *This,
  IN UINT64                                  StartIndex,
  IN UINT64                                  ConfigurationCount,
  IN EFI_GUID                                *KeyOwnerGuid OPTIONAL,
  OUT EFI_BLOCK_IO_CRYPTO_RESPONSE_CONFIGURATION_ENTRY
                                      *ConfigurationTable
);
```

Parameters

This

Pointer to the *EFI_BLOCK_IO_CRYPTO_PROTOCOL* instance.

StartIndex

Configuration table index at which to start the configuration query.

ConfigurationCount

Number of entries to return in the response table.

KeyOwnerGuid

Optional parameter to filter response down to entries with a given owner. A pointer to the Nil value can be used to return available entries. Set to NULL when no owner filtering is required.

ConfigurationTable

Table of configured configuration table entries (with no CryptoKey returned): configuration table index, *KeyOwnerGuid,* Capability. Should have sufficient space to store up to *ConfigurationCount* entries.

Description

The GetConfiguration() function allows the user to get the configuration of the inline cryptographic interface.

Retrieves, entirely or partially, the currently configured key table. Note that the keys themselves are not retrieved, but rather just indices, owner GUIDs and capabilities.

If fewer entries than specified by *ConfigurationCount* are returned, the Index field of the unused entries is set to *EFI_BLOCK_IO_CRYPTO_INDEX_ANY*.

Status Codes Returned

EFI_SUCCESS	The ICI is ready for use.
EFI_NO_RESPONSE	No response was received from the ICI
EFI_DEVICE_ERROR	An error occurred when attempting to access the ICI
EFI_INVALID_PARAMETER	This is NULL.
EFI_INVALID_PARAMETER	Configuration table is NULL
EFI_INVALID_PARAMETER	*StartIndex* is out of bounds

13.11.6 EFI_BLOCK_IO_CRYPTO_PROTOCOL.ReadExtended()

Summary

Reads the requested number of blocks from the device and optionally decrypts them inline.

Prototype

```
typedef EFI_STATUS
(EFIAPI *EFI_BLOCK_IO_CRYPTO_READ_EXTENDED) (
  IN EFI_BLOCK_IO_CRYPTO_PROTOCOL    *This,
  IN UINT32                          MediaId,
  IN EFI_LBA                         LBA,
  IN OUT EFI_BLOCK_IO_CRYPTO_TOKEN   *Token,
  IN UINT64                          BufferSize,
  OUT VOID                           *Buffer,
  IN UINT64                          *Index OPTIONAL,
  IN VOID                            *CryptoIvInput OPTIONAL
  );
```

Parameters

This

Pointer to the EFI_BLOCK_IO_CRYPTO_PROTOCOL instance.

MediaId

The media ID that the read request is for.

LBA

The starting logical block address to read from on the device. Type *EFI_LBA* is defined in the *EFI_BLOCK_IO_PROTOCOL* description.

Token

A pointer to the token associated with the transaction. Type *EFI_BLOCK_IO_CRYPTO_TOKEN* is defined in "Related Definitions" below.

BufferSize

The size of the *Buffer* in bytes. This must be a multiple of the intrinsic block size of the device.

Buffer

A pointer to the destination buffer for the data. The caller is responsible for either having implicit or explicit ownership of the buffer.

Index

A pointer to the configuration table index. This is optional.

CryptoIvInput

A pointer to a buffer that contains additional cryptographic parameters as required by the capability referenced by the configuration table index, such as cryptographic initialization vector.

Description

The *ReadExtended()* function allows the caller to perform a storage device read operation. The function reads the requested number of blocks from the device and then if *Index* is specified decrypts them inline. All the blocks are read and decrypted (if decryption requested), or an error is returned.

If there is no media in the device, the function returns *EFI_NO_MEDIA*. If the MediaId is not the ID for the current media in the device, the function returns *EFI_MEDIA_CHANGED*.

If *EFI_DEVICE_ERROR, EFI_NO_MEDIA,* or *EFI_MEDIA_CHANGED* is returned and non-blocking I/O is being used, the Event associated with this request will not be signaled.

In addition to standard storage transaction parameters (LBA, IO size, and buffer), this command will also specify a configuration table *Index* and *CryptoIvInput* when data has to be decrypted inline by the controller after being read from the storage device. If an *Index* parameter is not specified, no decryption is performed.

Related Definitions

```
typedef struct {
  EFI_EVENT             Event;
  EFI_STATUS            TransactionStatus;
}  EFI_BLOCK_IO_CRYPTO_TOKEN;
```

Event

If *Event* is NULL, then blocking I/O is performed. If *Event* is not NULL and non-blocking I/O is supported, then non- blocking I/O is performed, and *Event* will be signaled when the read request is completed and data was decrypted (when *Index* was specified).

TransactionStatus

Defines whether or not the signaled event encountered an error.

Status Codes Returned

EFI_SUCCESS	The read request was queued if Token-> Event is not **NULL**. The data was read correctly from the device if the Token-> Event is **NULL**.
EFI_DEVICE_ERROR	The device reported an error while attempting to perform the read operation and/or decryption operation.
EFI_NO_MEDIA	There is no media in the device.
EFI_MEDIA_CHANGED	The *MediaId* is not for the current media.
EFI_BAD_BUFFER_SIZE	The *BufferSize* parameter is not a multiple of the intrinsic block size of the device.
EFI_INVALID_PARAMETER	*This* is **NULL**, or the read request contains LBAs that are not valid, or the buffer is not on proper alignment
EFI_INVALID_PARAMETER	*CryptoIvInput* is incorrect.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.

13.11.7 EFI_BLOCK_IO_CRYPTO_PROTOCOL.WriteExtended()

Summary

Optionally encrypts a specified number of blocks inline and then writes to the device.

Prototype

```
typedef EFI_STATUS
(EFIAPI *EFI_BLOCK_IO_CRYPTO_WRITE_EXTENDED) (
  IN EFI_BLOCK_IO_CRYPTO_PROTOCOL        *This,
  IN UINT32                              MediaId,
  IN EFI_LBA                             LBA,
  IN OUT EFI_BLOCK_IO_CRYPTO_TOKEN       *Token,
  IN UINT64                              BufferSize,
  IN VOID                                *Buffer,
  IN UINT64                              *Index, OPTIONAL
  IN VOID                                *CryptoIvInput OPTIONAL
  );
```

Parameters

This
Pointer to the EFI_BLOCK_IO_CRYPTO_PROTOCOL instance.

MediaId
The media ID that the read request is for.

LBA
The starting logical block address to read from on the device. Type *EFI_LBA* is defined in the *EFI_BLOCK_IO_PROTOCOL* description.

Token
A pointer to the token associated with the transaction. Type *EFI_BLOCK_IO_CRYPTO_TOKEN* is defined in "Related Definitions" section for *ReadExtended()* function above.

BufferSize
The size of the *Buffer* in bytes. This must be a multiple of the intrinsic block size of the device.

Buffer
A pointer to the source buffer for the data.

Index
A pointer to the configuration table index. This is optional.

CryptoIvInput
A pointer to a buffer that contains additional cryptographic parameters as required by the capability referenced by the configuration table index, such as cryptographic initialization vector.

Description

The *WriteExtended()* function allows the caller to perform a storage device write operation. The function encrypts the requested number of blocks inline if *Index* is specified and then writes them to the device. All the blocks are encrypted (if encryption requested) and written, or an error is returned.

If there is no media in the device, the function returns *EFI_NO_MEDIA*. If the *MediaId* is not the ID for the current media in the device, the function returns *EFI_MEDIA_CHANGED*.

If *EFI_DEVICE_ERROR, EFI_NO_MEDIA, EFI_WRITE_PROTECTED* or *EFI_MEDIA_CHANGED* is returned and non-blocking I/O is being used, the Event associated with this request will not be signaled.

In addition to standard storage transaction parameters (LBA, IO size, and buffer), this command will also specify a configuration table *Index* and a *CryptoIvInput* when data has to be encrypted inline by the controller before being written to the storage device. If no *Index* parameter is specified, no encryption is performed.

Status Codes Returned

EFI_SUCCESS	The request to encrypt (optionally) and write was queued if Event is not **NULL**. The data was encrypted (optionally) and written correctly to the device if the Event is **NULL**.
EFI_WRITE_PROTECTED	The device cannot be written to.
EFI_NO_MEDIA	There is no media in the device.
EFI_MEDIA_CHANGED	The MediaId is not for the current media.
EFI_DEVICE_ERROR	The device reported an error while attempting to encrypt blocks or to perform the write operation.
EFI_BAD_BUFFER_SIZE	The BufferSize parameter is not a multiple of the intrinsic block size of the device.
EFI_INVALID_PARAMETER	This is NULL, or the write request contains LBAs that are not valid, or the buffer is not on proper alignment.
EFI_INVALID_PARAMETER	CryptoIvInput is incorrect.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.

13.11.8 EFI_BLOCK_IO_CRYPTO_PROTOCOL.FlushBlocks()

Summary

Flushes all modified data to a physical block device.

Prototype

```
typedef EFI_STATUS
(EFIAPI *EFI_BLOCK_IO_CRYPTO_FLUSH) (
  IN EFI_BLOCK_IO_CRYPTO_PROTOCOL        *This,
  IN OUT EFI_BLOCK_IO_CRYPTO_TOKEN       *Token
  );
```

Parameters

This

Pointer to the *EFI_BLOCK_IO_CRYPTO_PROTOCOL* instance.

Token

A pointer to the token associated with the transaction. Type *EFI_BLOCK_IO_CRYPTO_TOKEN* is defined in “Related Definitions” section for *ReadExtended()* function above.

Description

The *FlushBlocks()* function flushes all modified data to the physical block device. Any modified data that has to be encrypted must have been already encrypted as a part of *WriteExtended()* operation - inline crypto operation cannot be a part of flush operation.

All data written to the device prior to the flush must be physically written before returning *EFI_SUCCESS* from this function. This would include any cached data the driver may have cached, and cached data the device may have cached. A flush may cause a read request following the flush to force a device access.

If *EFI_DEVICE_ERROR, EFI_NO_MEDIA, EFI_WRITE_PROTECTED* or *EFI_MEDIA_CHANGED* is returned and non-blocking I/O is being used, the *Event* associated with this request will not be signaled.

Status Codes Returned

EFI_SUCCESS	The flush request was queued if Event is not **NULL**. All outstanding data was written correctly to the device if the Event is **NULL**.
EFI_DEVICE_ERROR	The device reported an error while attempting to write data.
EFI_WRITE_PROTECTED	The device cannot be written to.
EFI_NO_MEDIA	There is no media in the device.
EFI_MEDIA_CHANGED	The MediaId is not for the current media.
EFI_INVALID_PARAMETER	This is **NULL**.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.

13.12 Erase Block Protocol

13.12.1 EFI_ERASE_BLOCK_PROTOCOL

Summary

This protocol provides the ability for a device to expose erase functionality. This optional protocol is installed on the same handle as the *EFI_BLOCK_IO_PROTOCOL* or *EFI_BLOCK_IO2_PROTOCOL.*

GUID

```
#define EFI_ERASE_BLOCK_PROTOCOL_GUID \
{0x95A9A93E, 0x A86E, 0x4926, \
{0xaa, 0xef, 0x99, 0x18, 0xe7, 0x72, 0xd9, 0x87}}
```

Revision Number

```
#define EFI_ERASE_BLOCK_PROTOCOL_REVISION ((2<<16) \(60))
```

Protocol Interface Structure

```
typedef struct _EFI_ERASE_BLOCK_PROTOCOL {
  UINT64                        Revision;
  UINT32                        EraseLengthGranularity;
  EFI_BLOCK_ERASE               EraseBlocks;
}  EFI_ERASE_BLOCK_PROTOCOL;
```

Parameters

Revision

The revision to which the EFI_ERASE_BLOCK_PROTOCOL adheres. All future revisions must be backwards compatible. If a future version is not backwards compatible, it is not the same GUID.

EraseLengthGranularity

Returns the erase length granularity as a number of logical blocks. A value of 1 means the erase granularity is one logical block.

EraseBlocks

Erase the requested number of blocks from the device. See the *EraseBlocks()* function description.

13.12.2 EFI_ERASE_BLOCK_PROTOCOL.EraseBlocks()

Summary

Erase a specified number of device blocks.

Prototype

```
Typedef
EFI_STATUS*
(EFIAPI *EFI_BLOCK_ERASE)
IN EFI_BLOCK_IO_PROTOCOL        *This,
IN UINT32                       MediaId,
IN EFI_LBA                      LBA,
IN OUT EFI_ERASE_BLOCK_TOKEN    *Token,
IN UINTN                        Size
);
```

Parameters

This
Indicates a pointer to the calling context. Type is defined in the *EFI_ERASE_BLOCK_PROTOCOL* description.

MediaId
The media ID that the erase request is for.

LBA
The starting logical block address to be erased. The caller is responsible for erasing only legitimate locations. Type *EFI_LBA* is defined in the *EFI_BLOCK_IO_PROTOCOL* description.

Token
A pointer to the token associated with the transaction. Type *EFI_ERASE_BLOCK_TOKEN* is defined in "Related Definitions" below.

Size
The size in bytes to be erased. This must be a multiple of the physical block size of the device.

Description

The *EraseBlocks()* function erases the requested number of device blocks. Upon the successful execution of *EraseBlocks()* with an *EFI_SUCCESS* return code, any subsequent reads of the same LBA range would return an initialized/formatted value.

If there is no media in the device, the function returns *EFI_NO_MEDIA*. If the *MediaId* is not the ID for the current media in the device, the function returns *EFI_MEDIA_CHANGED*. The function must return *EFI_NO_MEDIA* or *EFI_MEDIA_CHANGED* even if LBA or Size are invalid so the caller can probe for changes in media state.

It is the intention of the *EraseBlocks()* operation to be at least as performant as writing zeroes to each of the specified LBA locations while ensuring the equivalent security.

On some devices, the granularity of the erasable units is defined by *EraseLengthGranularity* which is the smallest number of consecutive blocks which can be addressed for erase. The size of the *EraseLengthGranularity* is device specific and can be obtained from *EFI_ERASE_BLOCK_MEDIA* structure. The fields of *EFI_ERASE_MEDIA* are not the same as *EFI_BLOCK_IO_MEDIA,* so look at the *EFI_BLOCK_IO_PROTOCOL* and/or *EFI_BLOCK_IO2_PROTOCOL* on the handle for the complete list of fields, if needed. For optimal performance, the starting LBA to be erased shall be *EraseLengthGranularity* aligned and the Size shall be an integer multiple of an *EraseLengthGranularity*.

Related Definitions

```
typedef struct {
  EFI_EVENT                  Event;
  EFI_STATUS                 TransactionStatus;
}  EFI_ERASE_BLOCK_TOKEN;
```

Event

If *Event* is **NULL,** then blocking I/O is performed. If *Event* is not **NULL** and non-blocking I/O is supported, then non-blocking I/O is performed, and *Event* will be signaled when the erase request is completed.

TransactionStatus

Defines whether the signaled event encountered an error.

Status Codes Returned

EFI_SUCCESS	The erase request was queued if *Event* is not **NULL**. The data was erased correctly to the device if the *Event* is **NULL** to the device.
EFI_WRITE_PROTECTED	The device cannot be erased due to write protection.
EFI_DEVICE_ERROR	The device reported an error while attempting to perform the erase operation.
EFI_INVALID_PARAMETER	The erase request contains LBAs that are not valid.
EFI_NO_MEDIA	There is no media in the device.
EFI_MEDIA_CHANGED	The *MediaId* is not for the current media.

13.13 ATA Pass Thru Protocol

13.13.1 EFI_ATA_PASS_THRU_PROTOCOL

This section provides a detailed description of the *EFI_ATA_PASS_THRU_PROTOCOL*.

Summary

Provides services that allow ATA commands to be sent to ATA Devices attached to an ATA controller. Packet-based commands would be sent to ATAPI devices only through the Extended SCSI Pass Thru Protocol. While the *ATA_PASS_THRU* interface would expose an interface to the underlying ATA devices on an ATA controller, *EXT_SCSI_PASS_THRU* is responsible for exposing a packet-based command interface for the ATAPI devices on the same ATA controller.

GUID

```
#define EFI_ATA_PASS_THRU_PROTOCOL_GUID \
 {0x1d3de7f0,0x807,0x424f,\
  {0xaa,0x69,0x11,0xa5,0x4e,0x19,0xa4,0x6f}}
```

Protocol Interface Structure

```
typedef struct _EFI_ATA_PASS_THRU_PROTOCOL {
  EFI_ATA_PASS_THRU_MODE                    *Mode;
  EFI_ATA_PASS_THRU_PASSTHRU                PassThru;
  EFI_ATA_PASS_THRU_GET_NEXT_PORT           GetNextPort;
  EFI_ATA_PASS_THRU_GET_NEXT_DEVICE         GetNextDevice;
  EFI_ATA_PASS_THRU_BUILD_DEVICE_PATH       BuildDevicePath;
  EFI_ATA_PASS_THRU_GET_DEVICE              GetDevice;
  EFI_ATA_PASS_THRU_RESET_PORT              ResetPort;
```

(continues on next page)

(continued from previous page)

```
  EFI_ATA_PASS_THRU_RESET_DEVICE          ResetDevice;
}  EFI_ATA_PASS_THRU_PROTOCOL;
```

Parameters

Mode

A pointer to the *EFI_ATA_PASS_THRU_MODE* data for this ATA controller. *EFI_ATA_PASS_THRU_MODE* is defined in "Related Definitions" below.

PassThru

Sends an ATA command to an ATA device that is connected to the ATA controller. See the *PassThru()* function description.

GetNextPort

Retrieves the list of legal ports for ATA devices on an ATA controller. See the *GetNextPort()* function description.

GetNextDevice

Retrieves the list of legal ATA devices on a specific port of an ATA controller. See the *GetNextDevice()* function description.

BuildDevicePath

Allocates and builds a device path node for an ATA Device on an ATA controller. See the *BuildDevicePath()* function description.

GetDevice

Translates a device path node to a port and port multiplier port. See the *GetDevice()* function description.

ResetPort

Resets an ATA port or channel (PATA). This operation resets all the ATA devices connected to the ATA port or channel. See the *ResetPort()* function description.

ResetDevice

Resets an ATA device that is connected to the ATA controller. See the *ResetDevice()* function description.

Note: *The following data values in the EFI_ATA_PASS_THRU_MODE interface are read-only*.

Attributes

Additional information on the attributes of the ATA controller. See "Related Definitions" below for the list of possible attributes.

IoAlign

Supplies the alignment requirement for any buffer used in a data transfer. *IoAlign* values of 0 and 1 mean that the buffer can be placed anywhere in memory. Otherwise, *IoAlign* must be a power of 2, and the requirement is that the start address of a buffer must be evenly divisible by IoAlign with no remainder.

Related Definitions

```
typedef struct {
  UINT32                   Attributes;
  UINT32                   IoAlign;
}  EFI_ATA_PASS_THRU_MODE;

#define EFI_ATA_PASS_THRU_ATTRIBUTES_PHYSICAL     0x0001
#define EFI_ATA_PASS_THRU_ATTRIBUTES_LOGICAL      0x0002
#define EFI_ATA_PASS_THRU_ATTRIBUTES_NONBLOCKIO   0x0004
```

EFI_ATA_PASS_THRU_ATTRIBUTES_PHYSICAL

If this bit is set, then the *EFI_ATA_PASS_THRU_PROTOCOL* interface is for physical devices on the ATA controller.

EFI_ATA_PASS_THRU_ATTRIBUTES_LOGICAL

If this bit is set, then the *EFI_ATA_PASS_THRU_PROTOCOL* interface is for logical devices on the ATA controller.

EFI_ATA_PASS_THRU_ATTRIBUTES_NONBLOCKIO

If this bit is set, then the *EFI_ATA_PASS_THRU_PROTOCOL* interface supports non blocking I/O. Every *EFI_ATA_PASS_THRU_PROTOCOL* must support blocking I/O. The support of non-blocking I/O is optional.

Description

The *EFI_ATA_PASS_THRU_PROTOCOL* provides information about an ATA controller and the ability to send ATA Command Blocks to any ATA device attached to that ATA controller. To send ATAPI command blocks to ATAPI device attached to that ATA controller, use the *EXT_SCSI_PASS_THRU_PROTOCOL* interface.

The ATAPI devices support a small set of the non-packet-based ATA commands. The *EFI_ATA_PASS_THRU_PROTOCOL* may be used to send such ATA commands to ATAPI devices.

The printable name for the controller can be provided through the *EFI_COMPONENT_NAME2_PROTOCOL* for multiple languages.

The *Attributes* field of the Mode member of the *EFI_ATA_PASS_THRU_PROTOCOL* interface tells if the interface is for physical ATA devices or logical ATA devices. Drivers for non-RAID ATA controllers will set both the *EFI_ATA_PASS_THRU_ATTRIBUTES_PHYSICAL*, and the *EFI_ATA_PASS_THRU_ATTRIBUTES_LOGICAL* bits.

Drivers for RAID controllers that allow access to the physical devices and logical devices will produce two *EFI_ATA_PASS_THRU_PROTOCOL* interfaces: one with the just the *EFI_ATA_PASS_THRU_ATTRIBUTES_PHYSICAL* bit set and another with just the *EFI_ATA_PASS_THRU_ATTRIBUTES_LOGICAL* bit set. One interface can be used to access the physical devices attached to the RAID controller, and the other can be used to access the logical devices attached to the RAID controller for its current configuration.

Drivers for RAID controllers that do not allow access to the physical devices will produce one *EFI_ATA_PASS_THROUGH_PROTOCOL* interface with just the *EFI_ATA_PASS_THRU_LOGICAL* bit set. The interface for logical devices can also be used by a file system driver to mount the RAID volumes. An *EFI_ATA_PASS_THRU_PROTOCOL* with neither *EFI_ATA_PASS_THRU_ATTRIBUTES_LOGICAL* nor *EFI_ATA_PASS_THRU_ATTRIBUTES_PHYSICAL* set is an illegal configuration.

The Attributes field also contains the *EFI_ATA_PASS_THRU_ATTRIBUTES_NONBLOCKIO* bit. All *EFI_ATA_PASS_THRU_PROTOCOL* interfaces must support blocking I/O. If this bit is set, then the interface supports both blocking I/O and non-blocking I/O.

Each *EFI_ATA_PASS_THRU_PROTOCOL* instance must have an associated device path. Typically this will have an ACPI device path node and a PCI device path node, although variation will exist.

Additional information about the ATA controller can be obtained from protocols attached to the same handle as the *EFI_ATA_PASS_THRU_PROTOCOL*, or one of its parent handles. This would include the device I/O abstraction used to access the internal registers and functions of the ATA controller.

This protocol may also be used for PATA devices (or devices in a PATA-compatible mode). PATA devices are mapped to ports and port multiplier ports using the following table:

Table 13.45: PATA device mapping to ports and portmultiplier ports

PATA Device Connection	Emulated Port Number	Emulated Port Multiplier Port Number
Primary Master	0	0
Primary Slave	0	1
Secondary Master	1	0
Secondary Slave	1	1

13.13.2 EFI_ATA_PASS_THRU_PROTOCOL.PassThru()

Summary

Sends an ATA command to an ATA device that is attached to the ATA controller. This function supports both blocking I/O and non-blocking I/O. The blocking I/O functionality is required, and the non-blocking I/O functionality is optional.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_ATA_PASS_THRU_PASSTHRU) (
  IN EFI_ATA_PASS_THRU_PROTOCOL              *This,
  IN UINT16                                  Port,
  IN UINT16                                  PortMultiplierPort,
  IN OUT EFI_ATA_PASS_THRU_COMMAND_PACKET    *Packet,
  IN EFI_EVENT Event OPTIONAL
);
```

Parameters

This

A pointer to the *EFI_ATA_PASS_THRU_PROTOCOL* instance.

Port

The port number of the ATA device to send the command.

PortMultiplierPort

The port multiplier port number of the ATA device to send the command. If there is no port multiplier, then specify 0xFFFF.

Packet

A pointer to the ATA command to send to the ATA device specified by Port and *PortMultiplierPort*. See "Related Definitions" below for a description of *EFI_ATA_PASS_THRU_COMMAND_PACKET*.

Event

If non-blocking I/O is not supported then Event is ignored, and blocking I/O is performed. If *Event* is **NULL,** then blocking I/O is performed. If *Event* is not **NULL** and non blocking I/O is supported, then non-blocking I/O is performed, and *Event* will be signaled when the ATA command completes.

Related Definitions

```
typedef struct {
  EFI_ATA_STATUS_BLOCK              *Asb;
  EFI_ATA_COMMAND_BLOCK             *Acb;
  UINT64                            Timeout;
  VOID                              *InDataBuffer;
  VOID                              *OutDataBuffer;
  UINT32                            InTransferLength;
  UINT32                            OutTransferLength;
  EFI_ATA_PASS_THRU_CMD_PROTOCOL    Protocol;
  EFI_ATA_PASS_THRU_LENGTH          Length;
}  EFI_ATA_PASS_THRU_COMMAND_PACKET;
```

Timeout

The timeout, in 100 ns units, to use for the execution of this ATA command. A *Timeout* value of 0 means that this function will wait indefinitely for the ATA command to execute. If *Timeout* is greater than zero, then this function will return *EFI_TIMEOUT* if the time required to execute the ATA command is greater than *Timeout*.

InDataBuffer

A pointer to the data buffer to transfer between the ATA controller and the ATA device for read and bidirectional commands. For all write and non data commands where *InTransferLength* is 0 this field is optional and may be *NULL*. If this field is not *NULL,* then it must be aligned on the boundary specified by the *IoAlign* field in the *EFI_ATA_PASS_THRU_MODE* structure.

OutDataBuffer

A pointer to the data buffer to transfer between the ATA controller and the ATA device for write or bidirectional commands. For all read and non data commands where *OutTransferLength* is 0 this field is optional and may be *NULL*. If this field is not *NULL,* then it must be aligned on the boundary specified by the *IoAlign* field in the *EFI_ATA_PASS_THRU_MODE* structure.

InTransferLength

On input, the size, in bytes, of *InDataBuffer*. On output, the number of bytes transferred between the ATA controller and the ATA device. If *InTransferLength* is larger than the ATA controller can handle, no data will be transferred, *InTransferLength* will be updated to contain the number of bytes that the ATA controller is able to transfer, and *EFI_BAD_BUFFER_SIZE* will be returned.

OutTransferLength

On Input, the size, in bytes of *OutDataBuffer.* On Output, the Number of bytes transferred between ATA Controller and the ATA device. If *OutTransferLength* is larger than the ATA controller can handle, no data will be transferred, *OutTransferLength* will be updated to contain the number of bytes that the ATA controller is able to transfer, and *EFI_BAD_BUFFER_SIZE* will be returned.

Asb

A pointer to the sense data that was generated by the execution of the ATA command. It must be aligned to the boundary specified in the *IoAlign* field in the *EFI_ATA_PASS_THRU_MODE* structure.

Acb

A pointer to buffer that contains the Command Data Block to send to the ATA device specified by *Port* and *PortMultiplierPort*.

Protocol

Specifies the protocol used when the ATA device executes the command. Type *EFI_ATA_PASS_THRU_CMD_PROTOCOL* is defined below.

Length

Specifies the way in which the ATA command length is encoded. Type *EFI_ATA_PASS_THRU_LENGTH* is defined below.

```
typedef struct  _EFI_ATA_COMMAND_BLOCK {
  UINT8             Reserved1[2];

```

Description

The *PassThru()* function sends the ATA command specified by *Packet* to the ATA device specified by *Port* and *PortMultiplierPort*. If the driver supports non-blocking I/O and *Event* is not *NULL*, then the driver will return immediately after the command is sent to the selected device, and will later signal *Event* when the command has completed.

If the driver supports non-blocking I/O and *Event* is *NULL,* then the driver will send the command to the selected device and block until it is complete. If the driver does not support non-blocking I/O, then the *Event* parameter is ignored, and the driver will send the command to the selected device and block until it is complete.

If *Packet* is successfully sent to the ATA device, then *EFI_SUCCESS* is returned. If *Packet* cannot be sent because there are too many packets already queued up, then EFI_NOT_READY is returned. The caller may retry *Packet* at a later time. If a device error occurs while sending the *Packet* , then *EFI_DEVICE_ERROR* is returned. If a timeout occurs during the execution of *Packet,* then *EFI_TIMEOUT* is returned.

If *Port* or *PortMultiplierPort* are not in a valid range for the ATA controller, then *EFI_INVALID_PARAMETER* is returned. If *InDataBuffer, OutDataBuffer* or *Asb* do not meet the alignment requirement specified by the *IoAlign* field of the E *FI_ATA_PASS_THRU_MODE* structure, then *EFI_INVALID_PARAMETER* is returned. If any of the other fields of *Packet* are invalid, then *EFI_INVALID_PARAMETER* is returned.

If the data buffer described by *InDataBuffer* and *InTransferLength* is too big to be transferred in a single command, then no data is transferred and *EFI_BAD_BUFFER_SIZE* is returned. The number of bytes that can be transferred in a single command are returned in *InTransferLength*. If the data buffer described by *OutDataBuffer* and *OutTransferLength* is too big to be transferred in a single command, then no data is transferred and *EFI_BAD_BUFFER_SIZE* is returned. The number of bytes that can be transferred in a single command are returned in *OutTransferLength*.

If the command described in *Packet* is not supported by the host adapter, then *EFI_UNSUPPORTED* is returned.

If *EFI_SUCCESS, EFI_BAD_BUFFER_SIZE, EFI_DEVICE_ERROR,* or *EFI_TIMEOUT* is returned, then the caller must examine *Asb*.

If non-blocking I/O is being used, then the status fields in *Packet* will not be valid until the Event associated with *Packet* is signaled.

If *EFI_NOT_READY, EFI_INVALID_PARAMETER* or *EFI_UNSUPPORTED* is returned, then *Packet* was never sent, so the status fields in *Packet* are not valid. If non-blocking I/O is being used, the *Event* associated with *Packet* will not be signaled.

This function will determine if data transfer is necessary based on the *Acb->Protocol* and *Acb->Length* fields. The *Acb->AtaCommand* field is ignored except to copy it into the ATA Command register. The following table describes special programming considerations based on the protocol specified by *Acb->Protocol*.

Table 13.46: Special Programming Considerations

Protocol Value	Description
EFI_ATA_PASS_THRU_PROTOCOL_ATA_HARDWARE_RESET	For PATA devices, then *RST-* is asserted. For SATA devices, then *COMRESET* will be issued.
EFI_ATA_PASS_THRU_PROTOCOL_ATA_SOFTWARE_RESET	A software reset will be issued to the ATA device.
EFI_AT A_PASS_THRU_PROTOCOL_PIO_DATA_IN - EFI_ATA_PASS_THRU_PROTOCOL_FPDMA	The command is sent to the ATA device. If the value is inappropriate for the command specified by *Acb->AtaCommand,* the results are undefined.
E FI_ATA_PASS_THRU_RETURN_RESPONSE	This command will only return the contents of the ATA status block.

The ATA host and the ATA device should already be configured for the PIO, DMA, and UDMA transfer rates that are supported by the ATA controller and the ATA device. The results of changing the device's timings using this function are undefined.

If *Packet->Length* is not set to *EFI_ATA_PASS_THRU_LENGTH_NO_DATA_TRANSFER,* then if *EFI_ATA_PASS_THRU_LENGTH_BYTES* is set in *Packet->Length,* then *Packet->InTransferLength* and *Packet->OutTransferLength* are interpreted as bytes.

If *Packet->Length* is not set to *EFI_ATA_PASS_THRU_LENGTH_NO_DATA_TRANSFER,* then if *EFI_ATA_PASS_THRU_LENGTH_BYTES* is clear in *Packet->Length,* then *Packet->InTransferLength* and *Packet->OutTransferLength* are interpreted as blocks.

If *Packet->Length* is set to *EFI_ATA_PASS_THRU_LENGTH_SECTOR_COUNT,* then the transfer length will be programmed into *Acb->AtaSectorCount*.

If *Packet->Length* is set to *EFI_ATA_PASS_THRU_LENGTH_TPSIU,* then the transfer length will be programmed into the TPSIU.

- For PIO data transfers, the number of sectors to transfer is 2 *(Packet->Length & EFI_ATA_PASS_THRU_LENGTH_COUNT)* .

For all commands, the contents of the ATA status block will be returned in Asb.

Status Codes Returned

EFI_SUCCESS	The ATA command was sent by the host. For bi-directional commands, *InTransferLength* bytes were transferred from *InDataBuffer*. For write and bi-directional commands, *OutTransferLength* bytes were transferred by *OutDataBuffer*. See *Asb* for additional status information.
EFI_BAD_BUFFER_SIZE	The ATA command was not executed. The number of bytes that could be transferred is returned in *InTransferLength*. For write and bi-directional commands, *OutTransferLength* bytes were transferred by *OutDataBuffer*. See *Asb* for additional status information.
EFI_NOT_READY	The ATA command could not be sent because there are too many ATA commands already queued. The caller may retry again later.
EFI_DEVICE_ERROR	A device error occurred while attempting to send the ATA command. See Asb for additional status information.
EFI_INVALID_PARAMETER	*Port, PortMultiplierPort,* or the contents of *Acb* are invalid. The ATA command was not sent, so no additional status information is available.
EFI_UNSUPPORTED	The command described by the ATA command is not supported by the host adapter. The ATA command was not sent, so no additional status information is available.
EFI_TIMEOUT	A timeout occurred while waiting for the ATA command to execute. See *Asb* for additional status information.

13.13.3 EFI_ATA_PASS_THRU_PROTOCOL.GetNextPort()

Summary

Used to retrieve the list of legal port numbers for ATA devices on an ATA controller. These can either be the list of ports where ATA devices are actually present or the list of legal port numbers for the ATA controller. Regardless, the caller of this function must probe the port number returned to see if an ATA device is actually present at that location on the ATA controller.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_ATA_PASS_THRU_GET_NEXT_PORT) (
  IN EFI_ATA_PASS_THRU_PROTOCOL    *This,
```

(continues on next page)

(continued from previous page)

```
  IN OUT UINT16                    *Port
  );
```

Parameters

This

A pointer to the *EFI_ATA_PASS_THRU_PROTOCOL* instance.

Port

On input, a pointer to the port number on the ATA controller. On output, a pointer to the next port number on the ATA controller. An input value of *0xFFFF* retrieves the first port number on the ATA controller.

Description

The *GetNextPort()* function retrieves the port number on an ATA controller. If on input Port is *0xFFFF,* then the port number of the first port on the ATA controller is returned in *Port* and *EFI_SUCCESS* is returned.

If Port is the port number that was returned on the previous call to *GetNextPort(),* then the port number of the next port on the ATA controller is returned in Port, and EFI_SUCCESS is returned.

If *Port* is not *0xFFFF* and *Port* was not returned on the previous call to *GetNextPort(),* then *EFI_INVALID_PARAMETER* is returned.

If *Port* is the port number of the last port on the ATA controller, then *EFI_NOT_FOUND* is returned.

Status Codes Returned

EFI_SUCCESS	The next port number on the ATA controller was returned in *Port*.
EFI_NOT_FOUND	There are no more ports on this ATA controller.
EFI_INVALID_PARAMETER	*Port* is not *0xFFFF* and *Port* was not returned on a previous call to *GetNextPort()*.

13.13.4 EFI_ATA_PASS_THRU_PROTOCOL.GetNextDevice()

Summary

Used to retrieve the list of legal port multiplier port numbers for ATA devices on a port of an ATA controller. These can either be the list of port multiplier ports where ATA devices are actually present on port or the list of legal port multiplier ports on that port. Regardless, the caller of this function must probe the port number and port multiplier port number returned to see if an ATA device is actually present.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_ATA_PASS_THRU_GET_NEXT_DEVICE) (
  IN EFI_ATA_PASS_THRU_PROTOCOL    *This,
  IN UINT16                        Port,
  IN OUT UINT16                    *PortMultiplierPort
  );
```

Parameters

This

A pointer to the *EFI_ATA_PASS_THRU_PROTOCOL* instance.

Port

The port number present on the ATA controller.

PortMultiplierPort

On input, a pointer to the port multiplier port number of an ATA device present on the ATA controller. If on input a *PortMultiplierPort* of *0xFFFF* is specified, then the port multiplier port number of the first ATA device is returned. On output, a pointer to the port multiplier port number of the next ATA device present on an ATA controller.

Description

The *GetNextDevice()* function retrieves the port multiplier port number of an ATA device present on a port of an ATA controller.

If *PortMultiplierPort* points to a port multiplier port number value that was returned on a previous call to *GetNextDevice()* , then the port multiplier port number of the next ATA device on the port of the ATA controller is returned in *PortMultiplierPort,* and *EFI_SUCCESS* is returned.

If *PortMultiplierPort* points to *0xFFFF,* then the port multiplier port number of the first ATA device on port of the ATA controller is returned in *PortMultiplierPort* and *EFI_SUCCESS* is returned.

If *PortMultiplierPort* is not *0xFFFF* and the value pointed to by *PortMultiplierPort* was not returned on a previous call to *GetNextDevice(),* then *EFI_INVALID_PARAMETER* is returned.

If *PortMultiplierPort* is the port multiplier port number of the last ATA device on the port of the ATA controller, then *EFI_NOT_FOUND* is returned.

Status Codes Returned

EFI_SUCCESS	The port multiplier port number of the next ATA device on the port of the ATA controller was returned in *PortMultiplierPort*.
EFI_NOT_FOUND	There are no more ATA devices on this port of the ATA controller.
EFI_INVALID_PARAMETER	*PortMultiplierPort* is not *0xFFFF,* and *PortMultiplierPort* was not returned on a previous call to *GetNextDevice()*.

13.13.5 EFI_ATA_PASS_THRU_PROTOCOL.BuildDevicePath()

Summary

Used to allocate and build a device path node for an ATA device on an ATA controller.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_ATA_PASS_THRU_BUILD_DEVICE_PATH) (
  IN EFI_ATA_PASS_THRU_PROTOCOL       *This,
  IN UINT16                           Port,
  IN UINT16                           PortMultiplierPort,
  OUT EFI_DEVICE_PATH_PROTOCOL        **DevicePath
  );
```

Parameters

This

A pointer to the *EFI_ATA_PASS_THRU_PROTOCOL* instance.

Port

Port specifies the port number of the ATA device for which a device path node is to be allocated and built.

PortMultiplierPort

The port multiplier port number of the ATA device for which a device path node is to be allocated and built. If there is no port multiplier, then specify 0xFFFF.

DevicePath

A pointer to a single device path node that describes the ATA device specified by *Port* and *PortMultiplierPort*. This function is responsible for allocating the buffer *DevicePath* with the boot service *AllocatePool()*. It is the caller's responsibility to free *DevicePath* when the caller is finished with *DevicePath*.

Description

The *BuildDevicePath()* function allocates and builds a single device node for the ATA device specified by *Port* and *PortMultiplierPort*. If the ATA device specified by Port and *PortMultiplierPort* is not present on the ATA controller, then *EFI_NOT_FOUND* is returned. If *DevicePath* is *NULL,* then *EFI_INVALID_PARAMETER* is returned. If there are not enough resources to allocate the device path node, then *EFI_OUT_OF_RESOURCES* is returned.

Otherwise, *DevicePath* is allocated with the boot service *AllocatePool(),* the contents of *DevicePath* are initialized to describe the ATA device specified by *Port* and *PortMultiplierPort,* and *EFI_SUCCESS* is returned.

Status Codes Returned

EFI_SUCCESS	The device path node that describes the ATA device specified by *Port* and *PortMultiplierPort* was allocated and returned in *DevicePath*.
EFI_NOT_FOUND	The ATA device specified by *Port* and *PortMultiplierPort* does not exist on the ATA controller.
EFI_INVALID_PARAMETER	*DevicePath* is *NULL*.
EFI_OUT_OF_RESOURCES	There are not enough resources to allocate *DevicePath*.

13.13.6 EFI_ATA_PASS_THRU_PROTOCOL.GetDevice()

Summary

Used to translate a device path node to a port number and port multiplier port number.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_ATA_PASS_THRU_GET_DEVICE) (
  IN EFI_ATA_PASS_THRU_PROTOCOL     *This,
  IN EFI_DEVICE_PATH_PROTOCOL       *DevicePath,
  OUT UINT16                        *Port,
  OUT UINT16                        *PortMultiplierPort
  );
```

Parameters

This

A pointer to the *EFI_ATA_PASS_THRU_PROTOCOL* instance.

DevicePath

A pointer to the device path node that describes an ATA device on the ATA controller.

Port

On return, points to the port number of an ATA device on the ATA controller.

PortMultiplierPort

On return, points to the port multiplier port number of an ATA device on the ATA controller.

Description

The *GetDevice()* function determines the port and port multiplier port number associated with the ATA device described by *DevicePath*. If *DevicePath* is a device path node type that the ATA Pass Thru driver supports, then the ATA Pass Thru driver will attempt to translate the contents *DevicePath* into a port number and port multiplier port number.

If this translation is successful, then that port number and port multiplier port number are returned in *Port* and *PortMultiplierPort,* and *EFI_SUCCESS* is returned.

If *DevicePath, Port,* or *PortMultiplierPort* are *NULL,* then *EFI_INVALID_PARAMETER* is returned.

If *DevicePath* is not a device path node type that the ATA Pass Thru driver supports, then *EFI_UNSUPPORTED* is returned.

If *DevicePath* is a device path node type that the ATA Pass Thru driver supports, but there is not a valid translation from *DevicePath* to a port number and port multiplier port number, then *EFI_NOT_FOUND* is returned.

Status Codes Returned

EFI_SUCCESS	*DevicePath* was successfully translated to a port number and port multiplier port number, and they were returned in Port and *PortMultiplierPort*.
EFI_INVALID_PARAMETER	*DevicePath* is *NULL*.
EFI_INVALID_PARAMETER	*Port* is *NULL*
EFI_INVALID_PARAMETER	*PortMultiplierPort* is *NULL*
EFI_UNSUPPORTED	This driver does not support the device path node type in *DevicePath*.
EFI_NOT_FOUND	A valid translation from *DevicePath* to a port number and port multiplier port number does not exist.

13.13.7 EFI_ATA_PASS_THRU_PROTOCOL.ResetPort()

Summary

Resets a specific port on the ATA controller. This operation also resets all the ATA devices connected to the port.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_ATA_PASS_THRU_RESET_PORT) (
  IN EFI_ATA_PASS_THRU_PROTOCOL       *This,
  IN UINT16                           *Port
  );
```

Parameters

This

A pointer to the *EFI_ATA_PASS_THRU_PROTOCOL* instance.

Port

The port number on the ATA controller.

Description

The *ResetChannel()* function resets an a specific port on an ATA controller. This operation resets all the ATA devices connected to that port. If this ATA controller does not support a reset port operation, then *EFI_UNSUPPORTED* is returned.

If a device error occurs while executing that port reset operation, then *EFI_DEVICE_ERROR* is returned.

If a timeout occurs during the execution of the port reset operation, then *EFI_TIMEOUT* is returned.

If the port reset operation is completed, then *EFI_SUCCESS* is returned.

Status Codes Returned

EFI_SUCCESS	The ATA controller port was reset.
EFI_UNSUPPORTED	The ATA controller does not support a port reset operation.
EFI_DEVICE_ERROR	A device error occurred while attempting to reset the ATA port.
EFI_TIMEOUT	A timeout occurred while attempting to reset the ATA port.

13.13.8 EFI_ATA_PASS_THRU_PROTOCOL.ResetDevice()

Summary

Resets an ATA device that is connected to an ATA controller.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_ATA_PASS_THRU_RESET_DEVICE) (
  IN EFI_ATA_PASS_THRU_PROTOCOL    *This,
  IN UINT16                        Port,
  IN UINT16                        PortMultiplierPort
```

Parameters

This

A pointer to the *EFI_ATA_PASS_THRU_PROTOCOL* instance.

Port

Port represents the port number of the ATA device to be reset.

PortMultiplierPort

The port multiplier port number of the ATA device to reset. If there is no port multiplier, then specify 0xFFFF.

Description

The *ResetDevice()* function resets the ATA device specified by *Port* and *PortMultiplierPort*. If this ATA controller does not support a device reset operation, then *EFI_UNSUPPORTED* is returned.

If *Port* or *PortMultiplierPort* are not in a valid range for this ATA controller, then *EFI_INVALID_PARAMETER* is returned.

If a device error occurs while executing that device reset operation, then *EFI_DEVICE_ERROR* is returned.

If a timeout occurs during the execution of the device reset operation, then *EFI_TIMEOUT* is returned.

If the device reset operation is completed, then *EFI_SUCCESS* is returned.

Status Codes Returned

EFI_SUCCESS	The ATA device specified by *Port* and *PortMultiplierPort* was reset
EFI_UNSUPPORTED	The ATA controller does not support a device reset operation.
EFI_INVALID_PARAMETER	*Port* or *PortMultiplierPort* are invalid.
EFI_DEVICE_ERROR	A device error occurred while attempting to reset the ATA device specified by *Port* and *PortMultiplierPort*.
EFI_TIMEOUT	A timeout occurred while attempting to reset the ATA device specified by *Port* and *PortMultiplierPort*.

13.14 Storage Security Command Protocol

This section defines the storage security command protocol. This protocol is used to abstract mass storage devices to allow code running in the EFI boot services environment to send security protocol commands to mass storage devices without specific knowledge of the type of device or controller that manages the device. Functions are defined to send or retrieve security protocol defined data to and from mass storage devices. This protocol shall be supported on all physical and logical storage devices supporting the *EFI_BLOCK_IO_PROTOCOL* or *EFI_BLOCK_IO2_PROTOCOL* in the EFI boot services environment and one of the following command sets (or their alternative) at the bus level:

- TRUSTED SEND/RECEIVE commands of the ATA8-ACS command set or its successor
- SECURITY PROTOCOL IN/OUT commands of the SPC-4 command set or its successor.

If the mass storage device is part of a RAID set, the specific physical device may not support the block IO protocols directly, but they are supported by the logical device defining the RAID set. In this case the MediaId parameter may not be available and its value is undefined for this interface.

13.14.1 EFI_STORAGE_SECURITY_COMMAND_PROTOCOL

Summary

This protocol provides ability to send security protocol commands to mass storage devices.

GUID

```
#define EFI_STORAGE_SECURITY_COMMAND_PROTOCOL_GUID \
  {0xc88b0b6d, 0x0dfc, 0x49a7,\
  {0x9c, 0xb4, 0x49, 0x7, 0x4b, 0x4c, 0x3a, 0x78}}
```

Protocol Interface Structure

```
typedef struct _EFI_STORAGE_SECURITY_COMMAND_PROTOCOL {
  EFI_STORAGE_SECURITY_RECEIVE_DATA      ReceiveData;
  EFI_STORAGE_SECURITY_SEND_DATA         SendData;
}  EFI_STORAGE_SECURITY_COMMAND_PROTOCOL;
```

Parameters

ReceiveData

Issues a security protocol command to the requested device that receives data and/or the result of one or more commands sent by *SendData*. See the *ReceiveData()* function description.

SendData

Issues a security protocol command to the requested device. See the *SendData()* function description.

Description

The *EFI_STORAGE_SECURITY_COMMAND_PROTOCOL* is used to send security protocol commands to a mass storage device. Two types of security protocol commands are supported. *SendData* sends a command with data to a device. *ReceiveData* sends a command that receives data and/or the result of one or more commands sent by *SendData*.

The security protocol command formats supported shall be based on the definition of the SECURITY PROTOCOL IN and SECURITY PROTOCOL OUT commands defined in SPC-4. If the device uses the SCSI command set, no translation is needed in the firmware and the firmware can package the parameters into a SECURITY PROTOCOL IN or SECURITY PROTOCOL OUT command and send the command to the device. If the device uses a non-SCSI command set, the firmware shall map the command and data payload to the corresponding command and payload format defined in the non-SCSI command set (for example, TRUSTED RECEIVE and TRUSTED SEND in ATA8-ACS).

The firmware shall automatically add an *EFI_STORAGE_SECURITY_COMMAND_PROTOCOL* for any storage devices detected during system boot that support SPC-4, ATA8-ACS or their successors.

13.14.2 EFI_STORAGE_SECURITY_COMMAND_PROTOCOL.ReceiveData()

Summary

Send a security protocol command to a device that receives data and/or the result of one or more commands sent by *SendData*.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_STORAGE_SECURITY_RECEIVE_DATA) (
  IN EFI_STORAGE_SECURITY_COMMAND_PROTOCOL
                            *This,
  IN UINT32                  MediaId,
  IN UINT64                  Timeout,
  IN UINT8                   SecurityProtocol,
  IN UINT16                  SecurityProtocolSpecificData,
  IN UINTN                   PayloadBufferSize,
  OUT VOID                   *PayloadBuffer,
     OUT UINTN               *PayloadTransferSize
     );
```

Parameters

This
Indicates a pointer to the calling context. Type *EFI_STORAGE_SECURITY_COMMAND_PROTOCOL* is defined in the *EFI_STORAGE_SECURITY_COMMAND_PROTOCOL* description.

MediaId
ID of the medium to receive data from. If there is no block IO protocol supported by the physical device, the value of MediaId is undefined.

Timeout
The timeout, in 100ns units, to use for the execution of the security protocol command. A *Timeout* value of 0 means that this function will wait indefinitely for the security protocol command to execute. If *Timeout* is greater than zero, then this function will return *EFI_TIMEOUT* if the time required to execute the receive data command is greater than *Timeout*.

SecurityProtocolId
The value of the “Security Protocol” parameter of the security protocol command to be sent.

SecurityProtocolSpecificData

The value of the "Security Protocol Specific" parameter of the security protocol command to be sent. This value is in big-endian format.

PayloadBufferSize

Size in bytes of the payload data buffer.

PayloadBuffer

A pointer to a destination buffer to store the security protocol command specific payload data for the security protocol command. The caller is responsible for having either implicit or explicit ownership of the buffer.

PayloadTransferSize

A pointer to a buffer to store the size in bytes of the data written to the payload data buffer.

Description

The *ReceiveData* function sends a security protocol command to the given *MediaId*. The security protocol command sent is defined by *SecurityProtocolId* and contains the security protocol specific data *SecurityProtocolSpecificData*. The function returns the data from the security protocol command in *PayloadBuffer*.

For devices supporting the SCSI command set, the security protocol command is sent using the SECURITY PROTOCOL IN command defined in SPC-4.

For devices supporting the ATA command set, the security protocol command is sent using one of the TRUSTED RECEIVE commands defined in ATA8-ACS if *PayloadBufferSize* is non-zero. If the *PayloadBufferSize* is zero, the security protocol command is sent using the Trusted Non-Data command defined in ATA8-ACS.

If *PayloadBufferSize* is too small to store the available data from the security protocol command, the function shall copy *PayloadBufferSize* bytes into the *PayloadBuffer* and return *EFI_WARN_BUFFER_TOO_SMALL*.

If *PayloadBuffer* or *PayloadTransferSize* is *NULL* and *PayloadBufferSize* is non-zero, the function shall return *EFI_INVALID_PARAMETER*.

If the given *MediaId* does not support security protocol commands, the function shall return *EFI_UNSUPPORTED*. If there is no media in the device, the function returns *EFI_NO_MEDIA*. If the *MediaId* is not the ID for the current media in the device, the function returns *EFI_MEDIA_CHANGED*.

If the security protocol fails to complete within the *Timeout* period, the function shall return *EFI_TIMEOUT*.

If the security protocol command completes without an error, the function shall return *EFI_SUCCESS*. If the security protocol command completes with an error, the function shall return *EFI_DEVICE_ERROR*.

Status Codes Returned

EFI_SUCCESS	The security protocol command completed successfully.
EFI_WARN_BUFFER_TOO_SMALL	The *PayloadBufferSize* was too small to store the available data from the device. The *PayloadBuffer* contains the truncated data.
EFI_UNSUPPORTED	The given *MediaId* does not support security protocol commands.
EFI_DEVICE_ERROR	The security protocol command completed with an error.
EFI_NO_MEDIA	There is no media in the device.
EFI_MEDIA_CHANGED	The *MediaId* is not for the current media.
EFI_INVALID_PARAMETER	The *PayloadBuffer* or *PayloadTransferSize* is *NULL* and *PayloadBufferSize* is non-zero.
EFI_TIMEOUT	A timeout occurred while waiting for the security protocol command to execute.

13.14.3 EFI_STORAGE_SECURITY_COMMAND_PROTOCOL.SendData()

Summary

Send a security protocol command to a device.

Prototype

```
typedef
  EFI_STATUS
  (EFIAPI *EFI_STORAGE_SECURITY_SEND_DATA) (
    IN EFI_STORAGE_SECURITY_COMMAND_PROTOCOL
                                 *This,
    IN UINT32                     MediaId,
    IN UINT64                     Timeout,
    IN UINT8                      SecurityProtocolId,
    IN UINT16                     SecurityProtocolSpecificData,
    IN UINTN                      PayloadBufferSize,
    IN VOID                       *PayloadBuffer
      );
```

Parameters

This
Indicates a pointer to the calling context. Type *EFI_STORAGE_SECURITY_COMMAND_PROTOCOL* is defined in the *EFI_STORAGE_SECURITY_COMMAND_PROTOCOL* description.

MediaId
ID of the medium to send data to. If there is no block IO protocol supported by the physical device, the value of MediaId is undefined.

Timeout
The timeout, in 100ns units, to use for the execution of the security protocol command. A *Timeout* value of 0 means that this function will wait indefinitely for the security protocol command to execute. If *Timeout* is greater than zero, then this function will return *EFI_TIMEOUT* if the time required to execute the receive data command is greater than *Timeout*.

SecurityProtocolId
The value of the “Security Protocol” parameter of the security protocol command to be sent.

SecurityProtocolSpecificData
The value of the “Security Protocol Specific” parameter of the security protocol command to be sent.

PayloadBufferSize
Size in bytes of the payload data buffer.

PayloadBuffer
A pointer to a buffer containing the security protocol command specific payload data for the security protocol command.

Description

The *SendData* function sends a security protocol command containing the payload *PayloadBuffer* to the given *MediaId*. The security protocol command sent is defined by *SecurityProtocolId* and contains the security protocol specific data *SecurityProtocolSpecificData*. If the underlying protocol command requires a specific padding for the command payload, the SendData function shall add padding bytes to the command payload to satisfy the padding requirements.

For devices supporting the SCSI command set, the security protocol command is sent using the SECURITY PROTOCOL OUT command defined in SPC-4.

For devices supporting the ATA command set, the security protocol command is sent using one of the TRUSTED SEND commands defined in ATA8-ACS if *PayloadBufferSize* is non-zero. If the *PayloadBufferSize* is zero, the security protocol command is sent using the Trusted Non-Data command defined in ATA8-ACS.

If *PayloadBuffer* is *NULL* and *PayloadBufferSize* is non-zero, the function shall return *EFI_INVALID_PARAMETER*.

If the given *MediaId* does not support security protocol commands, the function shall return *EFI_UNSUPPORTED*. If there is no media in the device, the function returns *EFI_NO_MEDIA*. If the *MediaId* is not the ID for the current media in the device, the function returns *EFI_MEDIA_CHANGED*.

If the security protocol fails to complete within the *Timeout* period, the function shall return *EFI_TIMEOUT*.

If the security protocol command completes without an error, the function shall return *EFI_SUCCESS*. If the security protocol command completes with an error, the function shall return *EFI_DEVICE_ERROR*.

Status Codes Returned

EFI_SUCCESS	The security protocol command completed successfully.
EFI_UNSUPPORTED	The given *MediaId* does not support security protocol commands.
EFI_DEVICE_ERROR	The security protocol command completed with an error.
EFI_NO_MEDIA	There is no media in the device.
EFI_MEDIA_CHANGED	The *MediaId* is not for the current media.
EFI_INVALID_PARAMETER	The *PayloadBuffer* is *NULL* and *PayloadBufferSize* is non-zero.
EFI_TIMEOUT	A timeout occurred while waiting for the security protocol command to execute.

13.15 NVM Express Pass Through Protocol

13.15.1 EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL

This section provides a detailed description of the *EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL*.

Summary

This protocol provides services that allow NVM Express commands to be sent to an NVM Express controller or to a specific namespace in a NVM Express controller. This protocol interface is optimized for storage.

GUID

```
#define EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL_GUID \
  { 0x52c78312, 0x8edc, 0x4233,\
  { 0x98, 0xf2, 0x1a, 0x1a, 0xa5, 0xe3, 0x88, 0xa5 } };
```

Protocol Interface Structure

```
typedef struct  _EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL {
  EFI_NVM_EXPRESS_PASS_THRU_MODE                  *Mode;
  EFI_NVM_EXPRESS_PASS_THRU_PASSTHRU              PassThru;
  EFI_NVM_EXPRESS_PASS_THRU_GET_NEXT_NAMESPACE    GetNextNamespace;
  EFI_NVM_EXPRESS_PASS_THRU_BUILD_DEVICE_PATH     BuildDevicePath;
  EFI_NVM_EXPRESS_PASS_THRU_GET_NAMESPACE         GetNamespace;
}  EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL;
```

Parameters

Mode

A pointer to the *EFI_NVM_EXPRESS_PASS_THRU_MODE data for this NVM Express controller. EFI_NVM_EXPRESS_PASS_THRU_MODE is defined in "Related Definitions" below.*

PassThru

Sends an NVM Express Command Packet to an NVM Express controller. See the *EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL.PassThru()* function description.

GetNextNamespace

Retrieves the next namespace ID for this NVM Express controller. See the *EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL.GetNextNamespace()* function description.*

BuildDevicePath

Allocates and builds a device path node for a namespace on an NVM Express controller. See the *EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL.BuildDevicePath()* function description.*

GetNamespace

Translates a device path node to a namespace ID. See the *EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL.GetNamespace()* function description.

The following data values in the *EFI_NVM_EXPRESS_PASS_THRU_MODE* interface are read-only.

Attributes

Additional information on the attributes of the NVM Express controller. See "Related Definitions" below for the list of possible attributes.

IoAlign

Supplies the alignment requirement for any buffer used in a data transfer. *IoAlign* values of 0 and 1 mean that the buffer can be placed anywhere in memory. Otherwise, *IoAlign* must be a power of 2, and the requirement is that the start address of a buffer must be evenly divisible by *IoAlign* with no remainder.

NvmeVersion

Indicates the version of the NVM Express specification that the controller implementation supports. The format of this field is defined in the Version field of the Controller Registers in the *NVM Express Specification.*

Related Definitions

```
typedef struct {
  UINT32          Attributes;
  UINT32          IoAlign;
  UINT32          NvmeVersion;
}  EFI_NVM_EXPRESS_PASS_THRU_MODE;

#define EFI_NVM_EXPRESS_PASS_THRU_ATTRIBUTES_PHYSICAL    0x0001
#define EFI_NVM_EXPRESS_PASS_THRU_ATTRIBUTES_LOGICAL     0x0002
#define EFI_NVM_EXPRESS_PASS_THRU_ATTRIBUTES_NONBLOCKIO  0x0004
#define EFI_NVM_EXPRESS_PASS_THRU_ATTRIBUTES_CMD_SET_NVM 0x0008
```

EFI_NVM_EXPRESS_PASS_THRU_ATTRIBUTES_PHYSICAL

If this bit is set, then the EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL interface is for directly addressable namespaces.

EFI_NVM_EXPRESS_PASS_THRU_ATTRIBUTES_LOGICAL

If this bit is set, then the EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL interface is for a single volume logical namespace comprised of multiple namespaces.

EFI_NVM_EXPRESS_PASS_THRU_ATTRIBUTES_NONBLOCKIO

If this bit is set, then the *EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL* interface supports non-blocking I/O.

EFI_NVM_EXPRESS_PASS_THRU_ATTRIBUTES_CMD_SET_NVM
If this bit is set, then the *EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL* interface supports NVM command set.

Description

The *EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL* provides information about an NVM Express controller and the ability to send NVM Express commands to an NVM Express controller or to a specific namespace in a NVM Express controller.

- The printable name for the NVM Express controller can be provided through the* *EFI_COMPONENT_NAME_PROTOCOL* and the *EFI_COMPONENT_NAME2_PROTOCOL* for multiple languages.

The *Attributes* field of the *EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL* interface tells if the interface is for physical NVM Express controllers or logical NVM Express controllers. Drivers for non-RAID NVM Express controllers will set both the *EFI_NVM_EXPRESS_PASS_THRU_ATTRIBUTES_PHYSICAL,* and the *EFI_NVM_EXPRESS_PASS_THRU_ATTRIBUTES_LOGICAL* bits.

Drivers for RAID controllers that allow access to the physical controllers and logical controllers will produce two *EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL* interfaces: one with the just the *EFI_NVM_EXPRESS_PASS_THRU_ATTRIBUTES_PHYSICAL* bit set and another with just the *EFI_NVM_EXPRESS_PASS_THRU_ATTRIBUTES_LOGICAL* bit set. One interface can be used to access the physical controllers attached to the RAID controller, and the other can be used to access the logical controllers attached to the RAID controller for its current configuration.

Drivers for RAID controllers that do not allow access to the physical controllers will produce one *EFI_NVM_EXPRESS_PASS_THROUGH_PROTOCOL* interface with just the *EFI_NVM_EXPRESS_PASS_THRU_ATTRIBUTES_LOGICAL* bit set. The interface for logical controllers can also be used by a file system driver to mount the RAID volumes. An *EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL* with neither *EFI_NVM_EXPRESS_PASS_THRU_ATTRIBUTES_LOGICAL* nor *EFI_NVM_EXPRESS_PASS_THRU_ATTRIBUTES_PHYSICAL* set is an illegal configuration.

The *Attributes* field also contains the *EFI_NVM_EXPRESS_PASS_THRU_ATTRIBUTES_NONBLOCKIO* bit. All *EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL* interfaces must support blocking I/O. If this bit is set, then the interface supports both blocking I/O and non-blocking I/O.

The *Attributes* field also contains the *EFI_NVM_EXPRESS_PASS_THRU_ATTRIBUTES_CMD_SET_NVM* bit. If this bit is set, the controller supports the NVM Express command set.

- Each *EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL* instance must have an associated device path. Typically this will have an *ACPI* device path node and a *PCI* device path node, although variation will exist.

13.15.2 EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL.PassThru()

Summary

Sends an NVM Express Command Packet to an NVM Express controller or namespace. This function supports both blocking I/O and non-blocking I/O. The blocking I/O functionality is required, and the non-blocking I/O functionality is optional.

Prototype

```
typedef EFI_STATUS
  (EFIAPI *EFI_NVM_EXPRESS_PASS_THRU_PASSTHRU) (
  IN EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL             This,
  IN UINT32                                         NamespaceId,
```

(continues on next page)

(continued from previous page)

```
  IN OUT EFI_NVM_EXPRESS_PASS_THRU_COMMAND_PACKET   *Packet,
  IN EFI_EVENT                                      Event OPTIONAL
  );
```

Parameters

This

A pointer to the *EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL* instance. Type *EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL* is defined in See *NVM Express Pass Through Protocol*, above.

NamespaceId

A 32 bit namespace ID as defined in the NVMe specification to which the NVM Express Command Packet will be sent. A value of 0 denotes the NVM Express controller, a value of all *0xFF* 's (all bytes are *0xFF*) in the namespace ID specifies that the command packet should be sent to all valid namespaces.

Packet

A pointer to the NVM Express Command Packet. See "Related Definitions" below for a description of *EFI_NVM_EXPRESS_PASS_THRU_COMMAND_PACKET* .

Event

If non-blocking I/O is not supported then *Event* is ignored, and blocking I/O is performed. If *Event* is NULL, then blocking I/O is performed. If *Event* is not NULL and non-blocking I/O is supported, then non-blocking I/O is performed, and *Event* will be signaled when the NVM Express Command Packet completes.

Related Definitions

```
typedef struct {
  UINT64                        CommandTimeout;
  VOID                          TransferBuffer OPTIONAL;
  UINT32                        TransferLength OPTIONAL;
  VOID                          *MetaDataBuffer OPTIONAL;
  UINT32                        MetadataLength OPTIONAL;
  UINT8                         QueueType;
  EFI_NVM_EXPRESS_COMMAND       *NvmeCmd;
  EFI_NVM_EXPRESS_COMPLETION    *NvmeCompletion;
}  EFI_NVM_EXPRESS_PASS_THRU_COMMAND_PACKET;
```

CommandTimeout

The timeout in 100 ns units to use for the execution of this NVM Express Command Packet. A *Timeout* value of 0 means that this function will wait indefinitely for the command to execute. If *Timeout* is greater than zero, then this function will return *EFI_TIMEOUT* if the time required to execute the NVM Express command is greater than *Timeout* .

TransferBuffer

A pointer to the data buffer to transfer between the host and the NVM Express controller for read, write, and bi-directional commands. For all write and non-data commands where *TransferLength* is 0 this field is optional and may be NULL. If this field is not NULL, then it must be aligned on the boundary specified by the *IoAlign* field in the *EFI_NVM_EXPRESS_PASS_THRU_MODE* structure.

TransferLength

On input, the size in bytes of TransferBuffer*. On output, the number of bytes transferred to or from the NVM Express controller or namespace.

MetadataBuffer

A pointer to the optional metadata buffer to transfer between the host and the NVM Express controller. For all commands where no metadata is transferred between the host and the controller, this field is optional and may be NULL. If this field is not NULL, then it must be aligned on the boundary specified by the *IoAlign* field in the *EFI_NVM_EXPRESS_PASS_THRU_MODE* structure.

MetadataLength
On input, the size in bytes of *MetadataBuffer*. On output, the number of bytes transferred to or from the NVM Express controller or namespace.

QueueType
The type of the queue that the NVMe command should be posted to. A value of 0 indicates it should be posted to the Admin Submission Queue. A value of 1 indicates it should be posted to an I/O Submission Queue.

NvmeCmd
A pointer to an NVM Express Command Packet.

NvmeCompletion
The raw NVM Express completion queue entry as defined in the *NVM Express Specification*.

Description

The PassThru() function sends the NVM Express Command Packet specified by *Packet* to the NVM Express controller. If the driver supports non-blocking I/O and *Event* is not NULL, then the driver will return immediately after the command is sent to the selected controller, and will later signal Event when the command has completed.

If the driver supports non-blocking I/O and *Event i* s NULL, then the driver will send the command to the selected device and block until it is complete.

If the driver does not support non-blocking I/O, then the *Event* parameter is ignored, and the driver will send the command to the selected device and block until it is complete.

If *Packet* is successfully sent to the NVM Express controller, then *EFI_SUCCESS* is returned.

If a device error occurs while sending the *Packet,* then *EFI_DEVICE_ERROR* is returned.

If a timeout occurs during the execution of *Packet,* then *EFI_TIMEOUT* is returned.

If *NamespaceId* is invalid for the NVM Express controller, then *EFI_INVALID_PARAMETER* is returned.

If *TransferBuffer or MetadataBuffer* do not meet the alignment requirement specified by the *IoAlign* field of the *EFI_NVM_EXPRESS_PASS_THRU_MODE* structure, then *EFI_INVALID_PARAMETER* is returned. If the *QueueType* is not 0 (Admin Submission Queue) or 1 (I/O Submission Queue), then *EFI_INVALID_PARAMETER* is returned. If any of the other fields of *Packet* are invalid, then *EFI_INVALID_PARAMETER* is returned.

If the data buffer described by *TransferBuffer and TransferLength* is too big to be transferred in a single command, then no data is transferred and *EFI_BAD_BUFFER_SIZE* is returned. The number of bytes that can be transferred in a single command are returned in *TransferLength*.

If *EFI_SUCCESS*, *EFI_DEVICE_ERROR,* or *EFI_TIMEOUT* is returned, then the caller must examine the *NvmeCompletion* field in *Packet*.

If non-blocking I/O is being used, then the *NvmeCompletion* field in Packet will not be valid until the *Event* associated with *Packet* is signaled.

If *EFI_NOT_READY, EFI_INVALID_PARAMETER, EFI_BAD_BUFFER_SIZE, or EFI_UNSUPPORTED* is returned, then *Packet* was never sent, so the *NvmeCompletion* field in *Packet* is not valid. If non-blocking I/O is being used, the *Event* associated with *Packet* will not be signaled.

Status Codes Returned

EFI_SUCCESS	The NVM Express Command Packet was sent by the host. *TransferLength* bytes were transferred to or from *TransferBuffer*. See *NvmeCompletion* (above) for additional status information.

continues on next page

Table 13.56 – continued from previous page

EFI_BAD_BUFFER_SIZE	The NVM Express Command Packet was not executed. The number of bytes that could be transferred is returned in *TransferLength*.
EFI_NOT_READY	The NVM Express Command Packet could not be sent because the controller is not ready. The caller may retry again later.
EFI_DEVICE_ERROR	A device error occurred while attempting to send the NVM Express Command Packet. See *NvmeCompletion* (above) for additional status information.
EFI_INVALID_PARAMETER	*NamespaceId* or the contents of *EFI_NVM_EXPRESS_PASS_THRU_COMMAND_PACKET* are invalid. The NVM Express Command Packet was not sent, so no additional status information is available.
EFI_UNSUPPORTED	The command described by the NVM Express Command Packet is not supported by the NVM Express controller. The NVM Express Command Packet was not sent so no additional status information is available.
EFI_TIMEOUT	A timeout occurred while waiting for the NVM Express Command Packet to execute. See *NvmeCompletion* (above) for additional status information.

13.15.3 EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL.GetNextNamespace()

Summary

Used to retrieve the next namespace ID for this NVM Express controller.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_NVM_EXPRESS_PASS_THRU_GET_NEXT_NAMESPACE) (
IN EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL                    *This,
IN OUT UINT32                                            *NamespaceId
);
```

Parameters

This

A pointer to the *EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL* instance.

NamespaceId

On input, a pointer to a valid namespace ID onthis NVM Express controller or a pointer to the value*0xFFFFFFFF*. A pointer to the value *0xFFFFFFFF* retrievesthe first *valid namespace ID on this NVM Express controller.*

Description

The *EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL.GetNextNamespace()* function retrieves the next valid namespace ID on this NVMExpress controller. If on input the value pointed to by*NamespaceId* is *0xFFFFFFFF,* then the first valid namespaceID defined on the NVM Express controller is returned in thelocation pointed to by *NamespaceId* and a status of*EFI_SUCCESS* is returned.

If on input the value pointed to by *NamespaceId* is an invalidnamespace ID other than *0xFFFFFFFF,* then*EFI_INVALID_PARAMETER* is returned.

If on input the value pointed to by *NamespaceId* is a validnamespace ID, then the next valid namespace ID on the NVMExpress controller is returned in the location pointed to byNamespaceId, and *EFI_SUCCESS* is returned.

If the value pointed to by *NamespaceId* is the namespace ID ofthe last namespace on the NVM Express controller, then*EFI_NOT_FOUND* is returned.

Status Codes Returned

EFI_SUCCESS	The Namespace ID of the next *Namespace* was returned.
EFI_NOT_FOUND	There are no more namespaces defined on this controller.
EFI_INVALID_PARAMETER	*NamespaceId* is an invalid value other than *0xFFFFFFFF*.

13.15.4 EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL.BuildDevicePath()

Summary

Used to allocate and build a device path node for an NVMExpress namespace on an NVM Express controller.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_NVM_EXPRESS_PASS_THRU_BUILD_DEVICE_PATH) (
IN EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL        *This,
IN UINT32                                   NamespaceId,
OUT EFI_DEVICE_PATH_PROTOCOL                **DevicePath
);
```

Parameters

This

A pointer to the *EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL*instance. Type *EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL* is defined in *NVM Express Pass Through Protocol*.

NamespaceId

The NVM Express namespace ID for which a devicepath node is to be allocated and built.

DevicePath

A pointer to a single device path node thatdescribes the NVM Express namespace specified by *NamespaceId*. This function is responsible for allocating the buffer*DevicePath* with the boot service *AllocatePool()*. It is thecaller's responsibility to free *DevicePath* when the caller isfinished with *DevicePath*.

Description

The *EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL.BuildDevicePath()* function allocates and builds a single device path node for the NVM Express namespace specified by *NamespaceId*. If the *NamespaceId* is not valid, then *EFI_NOT_FOUND* is returned. If *DevicePath* is **NULL**, then *EFI_INVALID_PARAMETER* is returned. If there are not enough resources to allocate the device path node, then *EFI_OUT_OF_RESOURCES* is returned. Otherwise, *DevicePath* is allocated with the boot service *AllocatePool(),* the contents of *DevicePath* are initialized to describe the NVM Express namespace specified by *NamespaceId,* and *EFI_SUCCESS* is returned.

Status Codes Returned

EFI_SUCCESS	The device path node that describes the NVM Express namespace specified by *NamespaceId* was allocated and returned in *DevicePath*
EFI_NOT_FOUND	The *NamespaceId* is not valid.
EFI_INVALID_PARAMETER	*DevicePath* is NULL.
EFI_OUT_OF_RESOURCES	There are not enough resources to allocate the *DevicePath* node.

13.15.5 EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL.GetNamespace()

Summary

Used to translate a device path node to a namespace ID.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_NVM_EXPRESS_PASS_THRU_GET_NAMESPACE) (
IN EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL                 *This,
IN EFI_DEVICE_PATH_PROTOCOL                           *DevicePath,
OUT UINT32                                            *NamespaceId
);
```

Parameters

This

A pointer to the *EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL* instance. Type *EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL* is defined in *NVM Express Pass Through Protocol*.

DevicePath

A pointer to the device path node that describesan NVM Express namespace on the NVM Express controller.

NamespaceId

The NVM Express namespace ID contained in thedevice path node.

Description

The *EFI_NVM_EXPRESS_PASS_THRU_PROTOCOL.GetNamespace()* function determines the namespace ID associated with thenamespace described by *DevicePath*. If *DevicePath* is a device path node type that the NVM Express Pass Thru driversupports, then the NVM Express Pass Thru driver will attempt totranslate the contents *DevicePath* into a namespace ID. If this translation is successful, then that namespace ID is returned in *NamespaceId,* and *EFI_SUCCESS* is returned.

Status Codes Returned

EFI_INVALID_PARAMETER	If *DevicePath* or *NamespaceId* are NULL, then *EFI_INVALID_PARAMETER* is returned.
EFI_UNSUPPORTED	If *DevicePath* is not a device path node type that the NVM Express Pass Thru driver supports, then *EFI_UNSUPPORTED* is returned.
EFI_NOT_FOUND	If *DevicePath* is a device path node type that the NVM Express Pass Thru driver supports, but there is not a valid translation from *DevicePath* to a namespace ID, then *EFI_NOT_FOUND* is returned.

13.16 SD MMC Pass Thru Protocol

13.16.1 EFI_SD_MMC_PASS_THRU_PROTOCOL

This section provides a detailed description of the *EFI_SD_MMC_PASS_THRU_PROTOCOL*.

The protocol provides services that allow SD/eMMC commands to be sent to an SD/eMMC controller. All interfaces anddefinitions from this section apply equally to SD and eMMCcontrollers.

For the sake of brevity, the rest of this section refers only to SD devices and controllers and does not specifically mentioneMMC devices and controllers.

GUID

```
#define EFI_SD_MMC_PASS_THRU_PROTOCOL_GUID \
  { 0x716ef0d9, 0xff83, 0x4f69, \
  { 0x81, 0xe9, 0x51, 0x8b, 0xd3, 0x9a, 0x8e, 0x70 } }
```

Protocol Interface Structure

```
typedef struct _EFI_SD_MMC_PASS_THRU_PROTOCOL {
  UINTN                                      IoAlign
  EFI_SD_MMC_PASS_THRU_PASSTHRU              PassThru;
  EFI_SD_MMC_PASS_THRU_GET_NEXT_SLOT         GetNextSlot;
  EFI_SD_MMC_PASS_THRU_BUILD_DEVICE_PATH     BuildDevicePath;
  EFI_SD_MMC_PASS_THRU_GET_SLOT_NUMBER       GetSlotNumber;
  EFI_SD_MMC_PASS_THRU_RESET_DEVICE          ResetDevice;
} EFI_SD_MMC_PASS_THRU_PROTOCOL;
```

Parameters

IoAlign
Supplies the alignment requirement for any buffer used in a data transfer. *IoAlign* values of 0 and 1 mean that the buffer can be placed anywhere in memory. Otherwise, *IoAlign* must be a power of 2, and the requirement is that the start address of a buffer must be evenly divisible by *IoAlign* with no remainder.

PassThru
Sends SD command to the SD controller. See the *PassThru()* function description.

GetNextSlot
Retrieves a next slot on an SD controller. Seethe *GetNextSlot()* function description.

BuildDevicePath
Allocates and builds a device path nodefor an SD card on the SD controller. See the *BuildDevicePath()* function description.

GetSlotNumber
Retrieves the SD card slot number based onthe input device path. See the *GetSlotNumber()* function description.

ResetDevice
Resets an SD card connected to the SDcontroller. See the *ResetDevice()* function description.

13.16.2 EFI_SD_MMC_PASS_THRU_PROTOCOL.PassThru()

Summary

Sends SD command to an SD card that is attached to the SD controller.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SD_MMC_PASS_THRU_PASSTHRU) (
  IN EFI_SD_MMC_PASS_THRU_PROTOCOL                    *This,
  IN UINT8                                            Slot,
  IN OUT EFI_SD_MMC_PASS_THRU_COMMAND_PACKET          *Packet,
  IN EFI_EVENT                                        Event OPTIONAL
 );
```

Parameters

This

A pointer to the *EFI_SD_MMC_PASS_THRU_PROTOCOL* instance.

Slot

The slot number of the SD card to send the command to.

Packet

A pointer to the SD command data structure. See "Related Definitions" below for a description of *EFI_SD_MMC_PASS_THRU_COMMAND_PACKET*.

Event

If non-blockingI/O is not supported then *Event* is ignored, and blocking I/O is performed. If *Event* is *NULL,* then blockingI/O is performed. If *Event* is not *NULL* and non-blockingI/O is supported, then non-blockingI/O is performed, and *Event* will be signaled when the SDcommand completes

Related Definitions

```
typedef struct {
  EFI_SD_MMC_COMMAND_BLOCK            *SdMmcCmdBlk;
  EFI_SD_MMC_STATUS_BLOCK             *SdMmcStatusBlk;
  UINT64                              Timeout
  VOID                                *InDataBuffer;
  VOID                                *OutDataBuffer;
  UINT32                              InTransferLength;
  UINT32                              OutTransferLength;
  EFI_STATUS                          TransactionStatus;
} EFI_SD_MMC_PASS_THRU_COMMAND_PACKET;
```

SdMmcCmdBlk

A pointer to a command specific data buffer allocated and filled by the caller. See "Related Definitions" below for a description of *EFI_SD_MMC_COMMAND_BLOCK*.

SdMmcStatusBlk

A pointer to a command specific response data buffer allocated by the caller and filled by the PassThru function. See "Related Definitions" below for a description of *EFI_SD_MMC_STATUS_BLOCK*.

Timeout

The timeout, in 100 ns units, to use for the execution of this SDcommand. A *Timeout* value of 0 means that this function will wait indefinitely for the SDcommand to execute. If *Timeout* is greater than zero, then this function will return *EFI_TIMEOUT* if the time required to execute the SDcommand is greater than *Timeout*.

InDataBuffer

A pointer to a buffer for the data transferred from the SD card during processing of read and bidirectional commands. For all write and non-data commands this field is optional and may be *NULL*.

OutDataBuffer

A pointer to a buffer for the data to be transferred to the SD card during processing of write or bidirectional commands. For all read and non-data commands this field is optional and may be *NULL*.

InTransferLength

On input, the size, in bytes, of *InDataBuffer*. On output, the number of bytes transferred between the SD controller and the SD device. If *InTransferLength* is larger than the SD controller can handle, no data will be transferred, *InTransferLength* will be updated to contain the number of bytes that the SD controller is able to transfer, and *EFI_BAD_BUFFER_SIZE* will be returned.

OutTransferLength

On Input, the size, in bytes of *OutDataBuffer*. On Output, the Number of bytes transferred between SD Controller and the SD device. If *OutTransferLength* is larger than the SD controller can handle, no data will be transferred. *OutTransferLength* will be updated to contain the number of bytes that the SD controller is able to transfer, and *EFI_BAD_BUFFER_SIZE* will be returned.

TransactionStatus

Transaction status. When *PathThru()* function is used in a blocking mode, the status must be the same as the status returned by the *PathThru()* function. When *PathThru()* function is used in a non-blocking mode, the field is updated with the transaction status once transaction is completed.

Related Definitions

```
 typedef struct {
   UNIT16     CommandIndex;

```

Description

The *PassThru()* function sends the SD command specified by *Packet* to the SD card specified by *Slot* .

If *Packet* is successfully sent to the SD card, then *EFI_SUCCESS* is returned. If a device error occurs while sending the *Packet,* then *EFI_DEVICE_ERROR* is returned. If *Slot* is not in a valid range for the SD controller, then *EFI_INVALID_PARAMETER* is returned. If *Packet* defines a data command but both *InDataBuffer* and *OutDataBuffer* are *NULL* , *EFI_INVALID_PARAMETER* is returned.

Status Codes Returned

EFI_SUCCESS	The SD Command Packet was sent by the host.
EFI_DEVICE_ERROR	A device error occurred while attempting to send the SD command Packet.
EFI_INVALID_PARAMETER	*Packet, Slot,* or the contents of the *Packet* is invalid.
EFI_INVALID_PARAMETER	*Packet* defines a data command but both *InDataBuffer* and *OutDataBuffer* are *NULL.*
EFI_NO_MEDIA	SD Device not present in the *Slot.*
EFI_UNSUPPORTED	The command described by the SD Command Packet is not supported by the host controller.
EFI_BAD_BUFFER_SIZE	The *InTransferLength* or *OutTransferLength* exceeds the limit supported by SD card (i.e. if the number of bytes exceed the Last LBA).
EFI_DEVICE_ERROR	The command was not sent due to a device error

13.16.3 EFI_SD_MMC_PASS_THRU_PROTOCOL.GetNextSlot()

Summary

Used to retrieve next slot numbers supported by the SD controller. The function returns information about all available slots (populated or not-populated).

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SD_MMC_PASS_THRU_GET_NEXT_SLOT) (
  IN EFI_SD_MMC_PASS_THRU_PROTOCOL            *This,
  IN OUT UINT8                                *Slot
);
```

Parameters

This
A pointer to the EFI_SD_MMMC_PASS_THRU_PROTOCOL instance.

Slot
On input, a pointer to a slot number on the SD controller. On output, a pointer to the next slot number on the SD controller. An input value of *0xFF* retrieves the first slot number on the SD controller.

Description

The *GetNextSlot()* function retrieves the next slot number on an SD controller. If on input *Slot* is *0xFF,* then the slot number of the first slot on the SD controller is returned.

If *Slot* is a slot number that was returned on a previous call to *GetNextSlot(),* then the slot number of the next slot on the SD controller is returned.

If *Slot* is not *0xFF* and *Slot* was not returned on a previous call to *GetNextSlot(), EFI_INVALID_PARAMETER* is returned.

If *Slot* is the slot number of the last slot on the SD controller, then *EFI_NOT_FOUND* is returned.

Status Codes Returned

EFI_SUCCESS	The next slot number on the SD controller was returned in Slot.
EFI_NOT_FOUND	There are no more slots on this SD controller
EFI_INVALID_PARAMETER	*Slot* is not *0xFF* and *Slot* was not returned on a previous call to *GetNextSlot()*.

13.16.4 EFI_SD_MMC_PASS_THRU_PROTOCOL.BuildDevicePath()

Summary

Used to allocate and build a device path node for an SD card on the SD controller.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SD_MMC_PASS_THRU_BUILD_DEVICE_PATH) (
  IN EFI_SD_MMC_PASS_THRU_PROTOCOL              *This,
  IN UINT8                                      Slot,
  OUT EFI_DEVICE_PATH_PROTOCOL                  **DevicePath
);
```

Parameters

This

A pointer to the *EFI_SD_MMC_PASS_THRU_PROTOCOL* instance.

Slot

Specifies the slot number of the SD card for which a device path node is to be allocated and built.

DevicePath

A pointer to a single device path node that describes the SD card specified by *Slot*. This function is responsible for allocating the buffer *DevicePath* with the boot service *AllocatePool()*. It is the caller's responsibility to free *DevicePath* when the caller is finished with *DevicePath*.

Description

The *BuildDevicePath()* function allocates and builds a single device node for the SD card specified by *Slot*. If the SD card specified by *Slot* is not present on the SD controller, then *EFI_NOT_FOUND* is returned. If *DevicePath* is NULL, then *EFI_INVALID_PARAMETER* is returned. If there are not enough resources to allocate the device path node, then *EFI_OUT_OF_RESOURCES* is returned.

Otherwise, *DevicePath* is allocated with the boot service *AllocatePool()*, the contents of *DevicePath* are initialized to describe the SD card specified by *Slot*, and *EFI_SUCCESS* is returned.

Status Codes Returned

EFI_SUCCESS	The device path node that describes the SD card specified by Slot was allocated and returned in DevicePath.
EFI_NOT_FOUND	The SD card specified by Slot does not exist on the SD controller
EFI_INVALID_PARAMETER	DevicePath is NULL
EFI_OUT_OF_RESOURCES	There are not enough resources to allocate DevicePath

13.16.5 EFI_SD_MMC_PASS_THRU_PROTOCOL.GetSlotNumber()

Summary

This function retrieves an SD card slot number based on the input device path.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SD_MMC_PASS_THRU_GET_SLOT_NUMBER) (
  IN EFI_SD_MMC_PASS_THRU_PROTOCOL            *This,
  IN EFI_DEVICE_PATH_PROTOCOL                 *DevicePath,
  OUT UINT8                                   *Slot
);
```

Parameters

This

A pointer to the *EFI_SD_MMC_PASS_THRU_PROTOCOL* instance.

DevicePath

A pointer to the device path node that describes a SD card on the SD controller.

Slot

On return, points to the slot number of an SD card on the SD controller.

Description

The *GetSlotNumber()* function retrieves slot number for the SD card specified by the *DevicePath* node. If *DevicePath* is NULL, *EFI_INVALID_PARAMETER* is returned. If *DevicePath* is not a device path node type that the SD Pass Thru driver supports, *EFI_UNSUPPORTED* is returned.

Status Codes Returned

EFI_SUCCESS	SD card slot number is returned in *Slot*.
EFI_INVALID_PARAMETER	Slot or *DevicePath* is NULL.
EFI_UNSUPPORTED	*DevicePath* is not a device path node type that the SD Pass Thru driver supports.

13.16.6 EFI_SD_MMC_PASS_THRU_PROTOCOL.ResetDevice()

Summary

Resets an SD card that is connected to the SD controller.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SD_MMC_PASS_THRU_RESET_DEVICE) (
  IN EFI_SD_MMC_PASS_THRU_PROTOCOL              *This,
  IN UINT8                                      Slot
);
```

Parameters

This

A pointer to the *EFI_SD_MMC_PASS_THRU_PROTOCOL* instance.

Slot

Specifies the slot number of the SD card to be reset.

Description

The *ResetDevice()* function resets the SD card specified by *Slot*. If this SD controller does not support a device reset operation, *EFI_UNSUPPORTED* is returned. If *Slot* is not in a valid slot number for this SD controller, *EFI_INVALID_PARAMETER* is returned.

If the device reset operation is completed, *EFI_SUCCESS* is returned.

Status Codes Returned

EFI_SUCCESS	The SD card specified by Slot was reset.
EFI_UNSUPPORTED	The SD controller does not support a device reset operation.
EFI_INVALID_PARAMETER	Slot number is invalid.
EFI_NO_MEDIA	SD Device not present in the *Slot*.
EFI_DEVICE_ERROR	The reset command failed due to a device error

13.17 RAM Disk Protocol

13.17.1 EFI_RAM_DISK_PROTOCOL

Summary

RAM disk aware application invokes this protocol to register/unregister a specified RAM disk.

GUID

```
#define EFI_RAM_DISK_PROTOCOL_GUID \
     { 0xab38a0df, 0x6873, 0x44a9, \
     { 0x87, 0xe6, 0xd4, 0xeb, 0x56, 0x14, 0x84, 0x49 }}
```

Protocol Interface Structure

```
typedef struct  _EFI_RAM_DISK_PROTOCOL {
  EFI_RAM_DISK_REGISTER_RAMDISK              Register;
  EFI_RAM_DISK_UNREGISTER_RAMDISK            Unregister;
} EFI_RAM_DISK_PROTOCOL;
```

Members

Register

Register a RAM disk with specified buffer address, size and type.

Unregister

Unregister the RAM disk specified by a device path.

Description

This protocol defines a standard interface for UEFI applications, drivers and OS loaders to register/unregister a RAM disk.

The key points are:

- The consumer of this protocol is responsible for allocating/freeing memory used by RAM Disk if needed and deciding the initial content, as in most scenarios only the consumer knows which type and how much memory should be used.

13.17.2 EFI_RAM_DISK_PROTOCOL.Register()

Summary

This function is used to register a RAM disk with specified address, size and type.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_RAM_DISK_REGISTER_RAMDISK) (
  IN UINT64                              RamDiskBase,
  IN UINT64                              RamDiskSize,
  IN EFI_GUID                            *RamDiskType,
  IN EFI_DEVICE_PATH                     *ParentDevicePath OPTIONAL,
  OUT EFI_DEVICE_PATH_PROTOCOL           **DevicePath
);
```

Parameters

RamDiskBase

The base address of registered RAM disk.

RamDiskSize

The size of registered RAM disk.

RamDiskType

The type of registered RAM disk. The GUID can be any of the values defined in *RAM Disk*, or a vendor defined GUID.

ParentDevicePath

Pointer to the parent device path. If there is no parent device path then *ParentDevicePath* is *NULL*.

DevicePath

On return, points to a pointer to the device path of the RAM disk device. If *ParentDevicePath* is not *NULL,* the returned *DevicePath* is created by appending a RAM disk node to the parent device path. If *ParentDevicePath* is *NULL* , the returned *DevicePath* is a RAM disk device path without appending. This function is responsible for allocating the buffer *DevicePath* with the boot service *AllocatePool()*.

Description

The *Register* function is used to register a specified RAM Disk. The consumer of this API is responsible for allocating the space of the RAM disk and deciding the initial content of the RAM disk. The producer of this API is responsible for installing the RAM disk device path and block I/O related protocols on the RAM disk device handle.

RamDiskBase, RamDiskSize and *RamDiskType* are used to fill RAM disk device node. If *RamDiskSize* is 0, then *EFI_INVALID_PARAMETER* is returned. If *RamDiskType* is *NULL,* then *EFI_INVALID_PARAMETER* is returned.

DevicePath returns the device path of the registered RAM disk. If *DevicePath* is *NULL,* then *EFI_INVALID_PARAMETER* is returned. If there are not enough resources to allocate the device path node, then *EFI_OUT_OF_RESOURCES* is returned. Otherwise, *DevicePath* is allocated with the boot service *AllocatePool()*. If *ParentDevicePath* is not *NULL* the *DevicePath* instance is created by appending a RAM disk device node to the *ParentDevicePath*. If *ParentDevicePath* is *NULL* the *DevicePath* instance is a pure RAM disk device path. If the created *DevicePath* instance is already present in the handle database, then *EFI_ALREADY_STARTED* is returned.

Status Codes Returned

EFI_SUCCESS	The RAM disk is registered successfully.
EFI_INVALID_PARAMETER	*DevicePath* or *RamDiskType* is *NULL*.
EFI_INVALID_PARAMETER	*RamDiskSize* is 0.
EFI_ALREADY_STARTED	A Device Path Protocol instance to be created is already present in the handle database.
EFI_OUT_OF_RESOURCES	The RAM disk register operation fails due to resource limitation.

13.17.3 EFI_RAM_DISK_PROTOCOL.Unregister()

Summary

This function is used to unregister a RAM disk specified by *DevicePath*.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_RAM_DISK_UNREGISTER_RAMDISK) (
  IN EFI_DEVICE_PATH_PROTOCOL              *DevicePath
);
```

Parameters

DevicePath

A pointer to the device path that describes a RAM Disk device.

Description

The *Unregister* function is used to unregister a specified RAM Disk. The producer of this protocol is responsible for uninstalling the RAM disk device path and block I/O related protocols and freeing the RAM disk device handle. It is the consumer of this protocol's responsibility to free the memory used by this RAM disk.

Status Codes Returned

EFI_SUCCESS	The RAM disk is unregistered successfully.
EFI_INVALID_PARAMETER	*DevicePath* is NULL.
EFI_UNSUPPORTED	The device specified by *DevicePath* is not a valid ramdisk device path and not supported by the driver.
EFI_NOT_FOUND	The RAM disk pointed by *DevicePath* doesn't exist.

13.18 Partition Information Protocol

Summary

Installed along with EFI_BLOCK_IO_PROTOCOL for logical partitions. The PARTITION_INFORMATION_PROTOCOL provides cached partition information for MBR and GPT partition types.

Set System to 1 for partition identified as EFI_SYSTEM_PARTITIONs, otherwise set System to 0.

Set Type to PARTITION_TYPE_OTHER for partitions that are not GPT or MBR to indicate no cached data.

GUID

```
#define EFI_PARTITION_INFO_PROTOCOL_GUID \
  { \
  0x8cf2f62c, 0xbc9b, 0x4821, {0x80, 0x8d, 0xec, 0x9e, \
                    0xc4, 0x21, 0xa1, 0xa0} \
}
```

Protocol Interface Structure

```
#define EFI_PARTITION_INFO_PROTOCOL_REVISION 0x0001000
#define PARTITION_TYPE_OTHER 0x00
#define PARTITION_TYPE_MBR 0x01
#define PARTITION_TYPE_GPT 0x02

#pragma pack(1)

typedef struct {

  UINT32         Revision;
  UINT32         Type;
  UINT8          System;
  UINT8          Reserved[7];
  union {
   ///
   /// MBR data
   ///
   MBR_PARTITION_RECORD Mbr;

   ///
   /// GPT data
   ///
   EFI_PARTITION_ENTRY Gpt;
  } Info;
} EFI_PARTITION_INFO_PROTOCOL;
```

(continues on next page)

(continued from previous page)

```
#pragma pack()
```

See the *Legacy MBR* for the definition of MBR_PARTITION_RECORD.

See *Protective MBR* for the definition of EFI_PARTITION_ENTRY.

Parameters

Revision
Set to EFI_PARTITION_INFO_PROTOCOL_REVISION

Type
Partition info type (MBR, GPT, or Other).

System
If 1, partition describes an EFI System Partition.

Mbr
MBR information, if type is MBR.

Gpt
GPT information, if type is GPT

Description

The EFI_PARTITION_INFO_PROTOCOL is a simple protocol used to cache the partition information for potential File System Drivers.

Care must be taken by UEFI utilities that manipulate partitions. The utility must gain exclusive access to the physical disk to cause the partition driver to be stopped before it changes the partition information. If the exclusive request is not granted, then the utility must reset the system after changing the partition information.

When Type is set to PARTITION_TYPE_OTHER, data in the union Info is undefined.

13.19 NVDIMM Label Protocol

13.19.1 EFI_NVDIMM_LABEL_PROTOCOL

This section provides a detailed description of the EFI_NVDIMM_LABEL_PROTOCOL. For a high-level overview of the NVDIMM Label protocol see the Label Storage Area Description section.

Summary

Provides services that allow management of labels contained in a Label Storage Area that are associated with a specific NVDIMM Device Path. The labels describe how the data on the NVDIMM is organized in to namespaces, the layout being utilized, logical block size, unique label identifier, label state, etc.

GUID

```
#define EFI_NVDIMM_LABEL_PROTOCOL_GUID \
 {0xd40b6b80,0x97d5,0x4282, \
  {0xbb,0x1d,0x22,0x3a,0x16,0x91,0x80,0x58}}
```

Protocol Interface Structure

```
typedef struct  _EFI_NVDIMM_LABEL_PROTOCOL {
  EFI_NVDIMM_LABEL_STORAGE_INFORMATION   LabelStorageInformation;
  EFI_NVDIMM_LABEL_STORAGE_READ          LabelStorageRead;
  EFI_NVDIMM_LABEL_STORAGE_WRITE         LabelStorageWrite;
}
```

Parameters

LabelStorageInformation
Reports the size of the Label Storage Area and the maximum amount of label data that can be read in a single call to LabelStorageRead or written in a single call to LabelStorageWrite.

LabelStorageRead
Returns the label data stored for the NVDIMM at the requested offset and length in the Label Storage Area.

LabelStorageWrite
Writes the label data stored for the NVDIMM at the requested offset and length in the Label Storage Area.

13.19.2 EFI_NVDIMM_LABEL_PROTOCOL.LabelStorageInformation()

Summary

Retrieves the Label Storage Area size and the maximum transfer size for the LabelStorageRead and LabelStorageWrite methods that are associated with a specific NVDIMM Device Path.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_NVDIMM_LABEL_STORAGE_INFORMATION) (
  IN EFI_NVDIMM_LABEL_PROTOCOL            *This,
  OUT UINT32                              *SizeOfLabelStorageArea,
  OUT UINT32                              *MaxTransferLength
);
```

Parameters

This
A pointer to the EFI_NVDIMM_LABEL_PROTOCOL instance.

SizeOfLabelStorageArea
The size of the Label Storage Area for the NVDIMM in bytes.

MaxTransferLength
The maximum number of bytes that can be transferred in a single call to LabelStorageRead or LabelStorageWrite.

Description

Retrieves the Label Storage Area size and the maximum transfer size for the LabelStorageRead and LabelStorageWrite methods.

Status Codes Returned

EFI_SUCCESS	The size of theLabel Storage Area and maximum transfer size returned are valid.
EFI_ACCESS_DENIED	The Label Storage Area for the NVDIMM device is not currently accessible
EFI_DEVICE_ERROR	A physical device error occurred and the data transfer failed to complete

13.19.3 EFI_NVDIMM_LABEL_PROTOCOL.LabelStorageRead()

Summary

Retrieves label data for the NVDIMM for the requested byte offset and length from within the Label Storage Area that are associated with a specific NVDIMM Device Path.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_NVDIMM_LABEL_STORAGE_READ) (
  IN CONST EFI_NVDIMM_LABEL_PROTOCOL        *This,
  IN UINT32                                 Offset,
  IN UINT32                                 TransferLength,
  OUT UINT8                                 *LabelData
);
```

Parameters

This
A pointer to the EFI_NVDIMM_LABEL_PROTOCOL instance.

Offset
The byte offset within the Label Storage Area to read from.

TransferLength
Number of bytes to read from the Label Storage Area beginning at the byte Offset specified. A TransferLength of 0 reads no data.

LabelData
The return label data read at the requested offset and length from within the Label Storage Area.

Description

Retrieves the label data for the requested offset and length from within the Label Storage Area for the NVDIMM. See the Label Index Block and Label Definitions sections below for details on the contents of the label data.

Status Codes Returned

EFI_SUCCESS	The label data from the Label Storage Area for the NVDIMM was read successfully at the specified Offset and TransferLength and LabelData contains valid data.
EFI_INVALID_PARAMETER	Returned if any of the following are **TRUE**: - Offset > SizeOfLabelStorageArea reported in the LabelStorageInformation return data. - Offset + TransferLength is > SizeOfLabelStorageArea reported in the LabelStorageInformation return data. - TransferLength is > MaxTransferLength reported in the LabelStorageInformation return data.
EFI_ACCESS_DENIED	The Label Storage Area for the NVDIMM device is not currently accessible and labels cannot be read at this time.
EFI_DEVICE_ERROR	A physical device error occurred and the data transfer failed to complete

---

13.19.4 EFI_NVDIMM_LABEL_PROTOCOL.LabelStorageWrite()

Summary

Writes label data for the NVDIMM for the requested byte offset and length to the Label Storage Area that are associated with a specific NVDIMM Device Path.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_NVDIMM_LABEL_STORAGE_WRITE) (
  IN CONST EFI_NVDIMM_LABEL_PROTOCOL              *This,
  IN UINT32                                      Offset,
  IN UINT32                                      TransferLength,
  IN UINT8                                       *LabelData
);
```

Parameters

This

A pointer to the EFI_NVDIMM_LABEL_PROTOCOL instance.

Offset

The byte offset within the Label Storage Area to write to.

TransferLength

Number of bytes to write to the Label Storage Area beginning at the byte Offset specified. A TransferLength of 0 writes no data.

LabelBuffer

The label data to write at the requested offset and length from within the Label Storage Area.

Description

Writes the label data for the requested offset and length in to the Label Storage Area for the NVDIMM. See the Label Index Block and Label Definitions sections below for details on the contents of the label data.

Status Codes Returned

EFI_SUCCESS	The LabelData for the Label Storage Area for the NVDIMM was written successfully at the specified Offset and TransferLength.
EFI_INVALID_PARAMETER	Returned this status if any of the following are **TRUE**: - Offset > SizeOfLabelStorageArea reported in the LabelStorageInformation return data. - Offset + LabelBufferLength is > SizeOfLabelStorageArea reported in the LabelStorageInformation return data. - TransferLength is > MaxTransferLength reported in the LabelStorageInformation return data.
EFI_ACCESS_DENIED	The Label Storage Area for the NVDIMM device is not currently accessible and labels cannot be written at this time.
EFI_DEVICE_ERROR	A physical device error occurred and the data transfer failed to complete

---

Label Index Block Definitions

```
#define EFI_NVDIMM_LABEL_INDEX_SIG_LEN 16
#define EFI_NVDIMM_LABEL_INDEX_ALIGN 256

typedef struct EFI_NVDIMM_LABEL_INDEX_BLOCK {
    CHAR8  Sig[EFI_NVDIMM_LABEL_INDEX_SIG_LEN];
    UINT8  Flags[3];
    UINT8  LabelSize;
    UINT32  Seq;
    UINT64  MyOff;
    UINT64  MySize;
    UINT64  OtherOff;
    UINT64  LabelOff;
    UINT32  NSlot;
    UINT16  Major;
    UINT16  Minor;
    UINT64  Checksum;
    UINT8  Free[];
};
```

Sig
Signature of the Index Block data structure. Must be “NAMESPACE_INDEX0”.

Flags
Boolean attributes of this Label Storage Area. There are no flag bits defined at this time, so this field must be zero.

LabelSize
Size of each label in bytes, 128 bytes << LabelSize. 1 means 256 bytes, 2 means 512 bytes, etc. Shall be 1 or greater.

Seq
Sequence number used to identify which of the two Index Blocks is current. Only the least-significant two bits of this field are used in the current definition, rotating through the values depicted in Figure Z: Cyclic Sequence Numbers in Label Index Block below. The other bits must be zero.

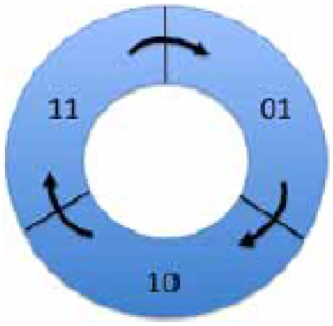

Fig. 13.2: Cyclic Sequence Numbers in Label Index Block

Each time an Index Block is written, the sequence number of the current Index Block is “incremented” by moving to the next value clockwise as shown.

Since there are two Index Blocks, written alternatively with successive sequence numbers, the older Index Block's sequence number will be immediately behind (counter-clockwise to) the current Index Block's sequence number. This property is used during software initialization to identify the current Index Block.

The sequence number 00 is used to indicate an uninitialized or invalid Index Block. Software never writes the sequence number 00, so a correctly check-summed Index Block with this sequence number probably indicates a critical error. When software discovers this case it treats it as an invalid Index Block indication. If two Index Blocks with identical sequence numbers are found, software shall treat the Index Block at the higher offset as the valid Index Block.

MyOff

The offset of this Index Block in the Label Storage Area.

MySize

The size of this Index Block in bytes. This field must be a multiple of the EFI_NVDIMM_LABEL_INDEX_ALIGN.

OtherOff

The offset of the other Index Block paired with this one.

LabelOff

The offset of the first slot where labels are stored in this Label Storage Area.

NSlot

The total number of slots for storing labels in this Label Storage Area. The NSlot field is typically calculated once at Label Storage Area initialization as described in the Initial Label Storage Area Configuration description.

Major

Major version number. Value shall be 1.

Minor

Minor version number. Value shall be 2.

Checksum

64-bit Fletcher64 checksum of all fields in this Index Block. This field is considered zero when the checksum is computed. For references to the Fletcher64 algorithm see "Links to UEFI-Related Documents" (http://uefi.org/uefi) under the heading "Fletcher64 Checksum Algorithm"

Free

Array of unsigned bytes implementing a bitmask that tracks which label slots are free. A bit value of 0 indicates in use, 1 indicates free. The size of this field is the number of bytes required to hold the bitmask with NSlot bits, padded with additional zero bytes to make the Index Block size a multiple of EFI_NVDIMM_LABEL_INDEX_ALIGN. Any bits allocated beyond NSlot bits must be zero.

The bitmask is organized where the label slot with the lowest offset in the Label Storage Area is tracked by the least significant bit of the first byte of the free array. Missing from the above layout is a total count of free slots. Since the common use case for the Label Storage Area is to read all labels during software initialization, it is recommended that software create a total free count (or in use count, or both), maintained at run-time. Rules for maintaining the Index Blocks are described in the Label Rules Description and Validating Index Blocks Description below. See the Initial Label Storage Area Configuration section for a more details on how the total number of slots are calculated.

Label Definitions

```
#define EFI_NVDIMM_LABEL_NAME_LEN 64

// Constants for Flags field
#define EFI_NVDIMM_LABEL_FLAGS_ROLABEL         0x00000001
#define EFI_NVDIMM_LABEL_FLAGS_LOCAL           0x00000002
#define EFI_NVDIMM_LABEL_FLAGS_SPACOOKIE_BOUND 0x00000010
```

(continues on next page)

(continued from previous page)

```
// This reserved flag is utilized on older implementations
// and has been deprecated. Do not use
#define EFI_NVDIMM_LABEL_FLAGS_RESERVED        0x00000004
#define EFI_NVDIMM_LABEL_FLAGS_UPDATING        0x00000008

typedef struct EFI_NVDIMM_LABEL{
  EFI_GUID      Uuid;
  CHAR8         Name[EFI_NVDIMM_LABEL_NAME_LEN];
  UINT32        Flags;

  UINT64        Checksum;
};
```

Uid

Unique Label Identifier UUID per RFC 4122. This field provides two functions. First, the namespace is associated with a UUID that software can use to uniquely identify it and providing a way for the namespace to be matched up with applications using it. Second, when multiple labels are required to describe a namespace, the UUID is the mechanism used to group the labels together. See the additional descriptions below describing the process for grouping the labels together by UUID, checking for missing labels, recovering from partial label changes, etc.

Name

NULL-terminated string using UTF-8 character formatting. The Name field is optionally used by software to store a more friendly name for the namespace. When this field is unused, it contains zeros.

If there is a name for a Local Namespace, as indicated by the EFI_NVDIMM_LABEL_FLAGS_LOCAL Flags, the name shall be stored in the first label of the set. All Name fields in subsequent labels for that Local Namespace are ignored. The Name field can be set at label creation time, or updated by following the rules in the additional descriptions below.

Flags

Boolean attributes of this namespace. See the additional description below on the use of the flags. The following values are defined:

EFI_NVDIMM_LABEL_FLAGS_ROLABEL - The label is read-only. This indicates the namespace is exported to a domain where configuration changes to the label are not allowed, such as a virtual machine. This indicates that device software and manageability software should refuse to make changes to the labels. This is a not a security mechanism, but a usability feature instead. In cases where **EFI_NVDIMM_LABEL_FLAGS_ROLABEL** is set, such as virtual machine guests, attempting to make configuration changes that affect the labels will fail (i.e. because the VM guest is not in a position to make the change correctly). For these cases, the VMM can set the EFI_NVDIMM_LABEL_FLAGS_ROLABEL bit on the label exposed to the guest to provide a better user experience where manageability refuses to make changes with a friendlier error message.

EFI_NVDIMM_LABEL_FLAGS_LOCAL - When set, the complete label set is local to a single NVDIMM Label Storage Area. When clear, the complete label set is contained on multiple NVDIMM Label Storage Areas. If NLabel is 1, then setting this flag is optional and it is implied that the EFI_NVDIMM_LABEL_FLAGS_LOCAL flag is set, as the complete label set is local to a single NVDIMM Label Storage Area.

EFI_NVDIMM_LABEL_FLAGS_UPDATING - When set, the label set is being updated. During an operation that may require updating multiple Label Storage Areas, the **EFI_NVDIMM_LABEL_FLAGS_UPDATING** flag is used to make the update atomic across interruptions. Updates happen in two phases, first writing the label with the **EFI_NVDIMM_LABEL_FLAGS_UPDATING** flag set, second writing the updated label without the EFI_NVDIMM_LABEL_FLAGS_UPDATING flag. As described in Recovery Steps for a Non-Local Label Set Description, this allows recovery actions during software initialization to either roll back or roll forward the multiple Label Storage Area changes. If **EFI_NVDIMM_LABEL_FLAGS_LOCA**L is set, the labels are contained in a single Label Storage Area and there is no need to set **EFI_NVDIMM_LABEL_FLAGS_UPDATING**, since the label can be written in one atomic operation.

EFI_NVDIMM_LABEL_FLAGS_SPACOOKIE_BOUND - When set, the SPALocationCookie in the namespace label is valid and should match the current value in the NFIT SPA Range Structure.

NLabel

Total number of labels describing this namespace. The NLabel field contains the number of labels required to describe a namespace.

Position

Position of this label in list of labels for this namespace. See NLabel description above. In the non-local case, each label is numbered as to its position in the list of labels using the Position field. For example, the common case where a namespace requires exactly one label, NLabel will be 1 and Position will be 0. If a namespace is built on an Interleave Set that spans multiple Label Storage Areas, each Label Storage Area will contain a label with increasing Position values to show each labels position in the set. For Local Namespaces, NLabel is valid only for the first label (lowest DPA) and position shall be 0 for that label. As part of organizing and validating the labels, SW shall have organized the labels from lowest to highest DPA so the first label in that ordered list of labels will have the lowest DPA. Position and NLabel for all subsequent labels in that namespace shall be set to 0xFF. See the Local Namespace description in the Validating Labels Description section for details.

SetCookie

Interleave Sets and the NVDIMMs they contain are defined in the NFIT and the Uuid in the label is used to uniquely identify each interleave set. The SetCookie is utilized by SW to perform consistency checks on the Interleave Set to verify the current physical device configuration matches the original physical configuration when the labels were created for the set. The label is considered invalid if the actual label set cookie doesn't match the cookie stored here. The SetCookie field in each label for that namespace is derived from data in the NVDIMM's Serial Presence Detect (SPD). See the SetCookie Description section below for SetCookie details. For references to the JEDEC SPD annex see "Links to UEFI-Related Documents" (http://uefi.org/uefi) under the heading "JEDEC SPD Annex"

LbaSize

This is the default logical block size in bytes and may be superseded by a block size that is specified in the AbstractionGuid.

- A non-zero value indicates the logical block size that is being emulated.
- A value of zero indicates an unspecified size and its meaning is implementation specific

Dpa

The DPA is the Device Physical Address where the NVM contributing to this namespace begins on this NVDIMM.

RawSize
The extent of the DPA contributed by this label.

Slot
Current slot in the Label Storage Area where this label is stored.

Alignment
Alignment hint used to advertise the preferred alignment of the data from within the namespace defined by this label.

Reserved
Shall be 0

TypeGuid
Range Type GUID that describes the access mechanism for the specified DPA range. The GUIDs utilized for the type are defined in the ACPI 6.0 specification in the NVDIMM FW Interface Table (NFIT) chapter. Those values are utilized here to describe the Type of namespace the label is describing. See the Address Range Type GUID field described in the System Physical Address (SPA) Range Structure table.

AddressAbstractionGuid
Identifies the address abstraction mechanism for this namespace. A value of 0 indicates no mechanism used.

SPALocationCookie
When creating the label, this value is set to the value from the NFIT SPA Range Structure if the SPALocationCookie flag (bit 2) is set. If *EFI_NVDIMM_LABEL_FLAGS_SPACOOKIE_BOUND* is set, the SPALocationCookie value stored in the namespace label should match the current value in the NFIT SPA Range Structure. Otherwise, the data may not be read correctly.

Reserved1
Shall be 0

Checksum
64-bit Fletcher64 checksum of all fields in this Label. This field is considered zero when the checksum is computed. For references to the Fletcher64 algorithm see "Links to UEFI-Related Documents" (http://uefi.org/uefi) under the heading "Fletcher64 Checksum Algorithm"

SetCookie Definition

```
typedef struct EFI_NVDIMM_LABEL_SET_COOKIE_INFO {
  typedef struct EFI_NVDIMM_LABEL_SET_COOKIE_MAP {
      UINT64 RegionOffset;
      UINT32 SerialNumber;
      UINT16 VendorId;
      UINT16 ManufacturingDate;
      UINT8 ManufacturingLocation;
      UINT8 Reserved[31];
  } Mapping[NumberOfNvdimmsInInterleaveSet];
};
```

NumberOfNvdimmsInInterleaveSet
The number of NVDIMMs in the interleave set. This is 1 if *EFI_NVDIMM_LABEL_FLAGS_LOCAL* Flags is set indicating a Local Namespaces.

RegionOffset
The Region Offset field from the ACPI NFIT NVDIMM Region Mapping Structure for a given entry. This determines the entry's position in the set. Region offset is 0 for Local Namespaces.

SerialNumber
The serial number of the NVDIMM, assigned by the module vendor. This field shall be set to the value of the NVDIMM Serial Presence Detect (SPD) Module Serial Number field defined by JEDEC with byte 0 set to SPD

byte 325, byte 1 set to SPD byte 326, byte 2 set to SPD byte 327, and byte 3 set to SPD byte 328. For references to the JEDEC SPD annex see "Links to UEFI-Related Documents" (http://uefi.org/uefi) under the heading "JEDEC SPD Annex"

VendorId

The identifier indicating the vendor of the NVDIMM. This field shall be set to the value of the NVDIMM SPD Module Manufacturer ID Code field with byte 0 set to DDR4 SPD byte 320 and byte 1 set to DDR4 SPD byte 321. For references to the JEDEC SPD annex see "Links to UEFI-Related Documents" (http://uefi.org/uefi) under the heading "JEDEC SPD Annex"

ManufacturingDate

The manufacturing date of the NVDIMM, assigned by the module vendor. This field shall be set to the value of the NVDIMM SPD Module Manufacturing Date field with byte 0 set to SPD byte 323 and byte 1 set to SPD byte 324. For references to the JEDEC SPD annex see "Links to UEFI-Related Documents" (http://uefi.org/uefi) under the heading "JEDEC SPD Annex"

ManufacturingLocation

The manufacturing location from for the NVDIMM, assigned by the module vendor. This field shall be set to the value of the NVDIMM SPD Module Manufacturing Location field (SPD byte 322). For references to the JEDEC SPD annex see "Links to UEFI-Related Documents" (http://uefi.org/uefi) under the heading "JEDEC SPD Annex"

Reserved

Shall be 0

SetCookie Description

This value is used to detect a change in the set configuration that has rendered existing data invalid and otherwise validates that the namespace belongs to a given NVDIMM. For each set create a data structure of the form EFI_NVDIMM_LABEL_SET_COOKIE_INFO. The SetCookie is then calculated by sorting the Mapping[] array by RegionOffset and then taking the Fletcher64 sum of the total EFI_NVDIMM_LABEL_SET_COOKIE_INFO structure. For references to the Fletcher64 algorithm see "Links to UEFI-Related Documents" (http://uefi.org/uefi) under the heading "Fletcher64 Checksum Algorithm"

13.19.5 Label Storage Area Description

Namespaces are defined by Labels which are stored in the Label Storage Area(s) and accessed via means described in the Label Rules Description.

The figure below shows the organization of the Label Storage Area. A header called the Index Block appears twice at the top of the Label Storage Area. This provides a powerfail-safe method for updating the information in the Label Storage Area by alternating between the two Index Blocks when writing (more details on this mechanism below).

Following the Index Blocks, an array for storing labels takes up the remainder of the Label Storage Area. The size of the Label Storage Area is NVDIMM implementation specific. The Index Blocks contain a bitmap which indicates which label slots are currently free and which are in use. The same powerfail-safe mechanism used for updating the Index Blocks covers the update of labels in the Label Storage Area.

The powerfail-safe update mechanism uses the principle of avoiding writes to active metadata. Instead, a shadow copy is updated and checksums and sequence numbers are used to make the last written copy active (a complete description of this mechanism is in Updating an Existing Label Description).

Initial Label Storage Area Configuration

The size of an Index Block depends on how many label slots fit into the Label Storage Area. The minimum size of an Index Block is 256 bytes and the size must be a multiple of EFI_NVDIMM_LABEL_INDEX_ALIGN bytes. As necessary, padding with zero bytes at the end of the structure is used to meet these size requirements. The minimum size of the Label Storage Area is large enough to hold 2 index blocks and 2 labels. As an example, for Label Storage Areas of 128KB and 256KB, the corresponding Index Block size is 256 or 512 bytes:

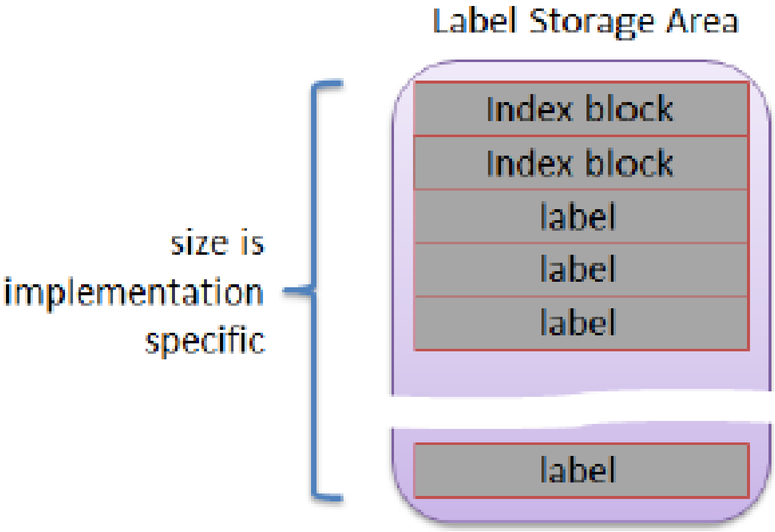

Fig. 13.3: Organization of the Label Storage Area

Table 13.70: Initial Label Storage Area Configuration

Example: <= 256 bytes		**Example**: > 256 bytes	
Size of the Index Block field up to the free field	72 bytes	Size of the Index Block field up to the free field	72 bytes
Bytes required for a bitmask of 1024 labels (the number of labels that fit into a 128KB Label Storage Area)	128 bytes	Bytes required for a bitmask of 2048 labels (the number of labels that fit into a 256KB Label Storage Area)	256 bytes
Padding to meet next increment of 256 bytes	56 bytes	Padding to meet next increment of 256 bytes	184
Total size of the Index Block	256 bytes		512 bytes

Before Index Blocks and labels can be utilized, the software managing the Label Storage Area must determine the total number of labels that will be supported and utilizing the description above, calculate the size of the Index Blocks required. Once the initial Label Storage Area is written with the first Index Blocks (typically done when the first Label needs to be written), the total number of slots is fixed and this initial calculation is not performed again.

Label Description

Each slot in the Label Storage Area is either free or contains an active label.

In the cases where multiple labels are used to describe a namespace, the label fields NLabel and Position provide an ordering ("label one of two, label two of two") so that incomplete label sets can be detected.

A namespace is described by one or more labels. Local namespaces describe one or more device physical address ranges from a single NVDIMM while non-Local namespaces describe a single SPA range that may have contributions from 2 or more NVDIMMs. The number of labels needed to describe a non-Local namespace is equal to the number of NVDIMMs contributing to the SPA range, 1 per-NVDIMM. For a Local namespace any number, up to the max number of labels supported by the Index Block / Label Storage Area, of device physical address ranges in the given NVDIMM can be described.

Label Rules Description

All the algorithms related to labels in this specification assume single-threaded / non-reentrant execution. The algorithm for updating labels guarantees that at least one slot in the Label Storage Area will be free, ensuring it is always possible to update labels using this method.

Software shall maintain the following invariants to use the on-media data structures correctly and to inter-operate with other software components.

At all times, the following must be **TRUE**:

- The size of the Label Storage Area is known (this must be **TRUE** even if no namespace metadata has been written yet). The Label Storage Area size is queried from the NVDIMM.
- The Label Storage Area either contains no valid Index Blocks, indicating there are no labels on the NVDIMM (all slots free), or the validation rules below produce a single, valid, Index Block.
- 2 free slots are required in order to add a Label. Having only a single free slot indicates that no more labels can be added. Only fully written, active labels, and full-written labels with the EFI_NVDIMM_LABEL_FLAGS_UPDATING flag are marked in-use by the Index Block.
- Write to active label slots are not allowed; all updates to labels must be done by writing to free slots and then updating the Index Block to make them active.

Validating Index Blocks Description

The following tests shall pass before software considers Index Blocks valid:

- Both Index Blocks must be read successfully from the Label Storage Area.
- Any Index Block with an incorrect **Sig** field is invalid.
- Any Index Block with an incorrect **Checksum** is invalid.
- Any Index Block with an incorrect **MyOff, MySize**, or **OtherOff** field is invalid.
- Any Index Block with a sequence number **Seq** of zero is invalid.
- If two valid Index Blocks remain, after passing all the above tests, and their sequence numbers match, the Index Block at the lower offset in the Label Storage Area is invalid.
- If two Index Blocks remain, after passing all the above tests, their sequence numbers are compared and the block whose sequence number is the predecessor of the other (immediately counter-clockwise to it, as shown in **Figure Z: Cyclic Sequence Numbers in Label Index Block** in the **Seq** description) is invalid.
- If one Index Block remains, that is the current, valid block and software should make note that the next update to the Index Block will write the other Index Block. However, if no valid Index Blocks remain, all slots are considered free and the next update to the index will write to the lower-addressed block location (i.e. the start of the Label Storage Area).

Validating Labels Description

The following tests shall pass before software considers individual Labels slots valid:

- The corresponding free bit for the label **Slot** in the Index Block **Free** array must be clear (i.e. label slot is active).
- The label **Checksum** shall validate.
- The Slot value in the Label shall match the logical slot location of the Label.
- The **SetCookie** field in the label matches the expected value as described in **SetCookie Definition**.

- The address range type GUID **TypeGuid** shall match the System Physical Address Range Structure that describes the access mechanism for this namespace. For Hardware Block Namespaces it shall match the GUID for the NVDIMM Block Data Window Region.

For Local Namespaces:

- If 2 or more labels share the same **Dpa** value, all labels with the duplicated value are considered invalid.
- The count of all valid labels for a given namespace **Uuid** shall match the **NLabel** value in the first label.
- The first label, the label with the lowest **Dp** a value, shall have **Position 0** and non-zero **NLabel** value.
- All labels other than the first have **Position** and **NLabel** set to 0xff.

Reading Labels Description

For a given NVDIMM, the following steps are used to read one or more labels for validation and namespace assembly:

Pre-condition: both Index Blocks have been read and the rules in **Validating Index Blocks Description** have been followed to determine the current valid Index Block.

- Check that the label at a given slot is active. Specifically bit N is clear in the Free bitmask field where N corresponds to the logical slot number label.
- Read the label in that slot at the offset given by: **(2 * sizeof(EFI_NVDIMM_LABEL_INDEX_BLOCK) + slot * sizeof(EFI_NVDIMM_LABEL))**

Recovery Steps for a Non-Local Label Set Description

Given that a non-Local Label set potentially spans multiple Label Storage Areas for multiple NVDIMMs it is not possible to guarantee that the set is updated atomically with respect to unexpected system interruption. Recovery shall be performed before validating the set to roll the set forward to a consistent state or invalidate / free the label slots corresponding to an inconsistent state. Note that individual Index Block updates are safe with respect to unexpected system interruption given the sequence number mechanism for indicating the currently active Index Block.

The sequence below describes how the **EFI_NVDIMM_LABEL_FLAGS_UPDATING** flag is used when validating a non-Local Label Set.

- Pre-condition: The labels have been read.
- For each set of labels with the same UUID, if no labels in the set are found with the **EFI_NVDIMM_LABEL_FLAGS_UPDATING** flag set, then no recovery is required for that set.
- For the sets where **EFI_NVDIMM_LABEL_FLAGS_UPDATING** appear at least once, if the set is incomplete (some NVDIMMs in the set do not contain a label in the Label Storage Area with the UUID), the recovery action is to roll back the interrupted create operation that left this state. I.e. for each NVDIMM in the set containing a label with the given UUID, delete the label.
- For a set where **EFI_NVDIMM_LABEL_FLAGS_UPDATING** appears at least once and the set is otherwise complete (each NVDIMM in the Interleave Set contains a label with the UUID, some with **EFI_NVDIMM_LABEL_FLAGS_UPDATING** set, some with **EFI_NVDIMM_LABEL_FLAGS_UPDATING** clear), the recovery action is to roll forward the change that was interrupted. I.e. for each **NVDIMM** in the set If **EFI_NVDIMM_LABEL_FLAGS_UPDATING** is set, write an updated label with **EFI_NVDIMM_LABEL_FLAGS_UPDATING** clear and with the name field copied from the first label in the set (the label with a Position field of 0).

Recovery Steps for a Local Label Set Description

Given that a Local Label set is always contained in a single **Label Storage Area** for a single NVDIMM, labels are added/updated atomically, as long as there is a free Label available as outlined in **Label Storage Area Description** and **Label Description. EFI_NVDIMM_LABEL_FLAGS_UPDATING** should not be set for Local sets and no additional recovery is required.

Assembling Labels into Complete Sets Description

After collecting a set of labels corresponding to a given UUID and performing the recovery actions on the set, software shall follow the steps in this section to assemble complete sets of labels representing usable namespaces:

1. Precondition: Labels have been read and the recovery actions have been taken.
2. For each set of labels with the same Uuid
    a. If the set describes a non-Local namespace, it is considered complete if labels with unique **Position** fields are found for every position from **0** to **NLabel–1**.
    b. If the set describes a Local namespace, it is considered complete if a valid first label is found, according to the validation rules, and the number of labels in the set matches
    c. **NLabel**.

The recovery action for the case where software finds incomplete namespaces is implementation specific.

Updating an Existing Label Description

Updating an existing label in the Label Storage Area requires the software to follow these steps:

1. Pre-conditions: the software has an updated label constructed to be written to a specific NVDIMM's Label Storage Area. There is at least 1 free slot in the Label Storage Area Free bitmask.
2. The software chooses a free slot from the Index Block, fills in that slot number in the label's Slot field
3. The software writes the updated label to that slot in the Label Storage Area
4. The software updates the Index Block by taking the current Index Block, setting the appropriate bit in the Free field to make the old version of the label inactive and clearing the appropriate bit in the Free field to make the new version active, incrementing the sequence number as shown in Figure Z: Cyclic Sequence Numbers in Label Index Block in the Seq description, and then writing the Index Block over the inactive Index Block location (making this location the new active Index Block if the write succeeds)

Deleting a Label Description

The software updates the Index Block by taking the current active Index Block, setting the appropriate bit in the Free field to make the deleted label inactive, incrementing the sequence number as shown in Figure Z: Cyclic Sequence Numbers in Label Index Block in the Seq description, and then writing the new Index Block over the inactive Index Block location (making this location the new active Index Block if the write succeeds)

Creating Namespaces Description

Namespace creation procedures are different for Local vs non-Local namespaces. A Local namespace is created from 1 or more DPA ranges of a single NVDIMM, while a non-Local namespace is created from a single range contributed from multiple NVDIMMs. Both procedures share a common flow for establishing new labels in an Index Block.

Writing New Labels Description

Transitioning a label slot from free to active shall follow this sequence:

1. Pre-conditions: the software has a new label constructed to be written to a specific NVDIMM's Label Storage Area. Because of the free Label rules outlined in Label Storage Area Description and Label Description, there are at least 2 free slots in the Label Storage Area as described in the Label Rules Description and Label Description sections. Choose a free slot from the Index Block, fills in that slot number in the label's Slot field
2. Write the new label to that slot in the Label Storage Area
3. Update the Index Block by taking the current Index Block, clearing the appropriate bit in the Free field, incrementing the sequence number as shown in Figure Z: Cyclic Sequence Numbers in Label Index Block in the Seq description, and then writing the Index Block over the inactive Index Block location (making this location the new active Index Block if the write succeeds)

Creating a Non-Local Namespace

When creating a new Non-Local Namespace, the software shall follow these steps:

1. Pre-conditions: the labels to be written to each NVDIMM contributing to the namespace have been constructed, each with a unique **Position** field from **0 to NLabel–1**, and all labels with the same new UUID. All Index Blocks involved have at least 2 label slots free as described in the **Label Rules Description** and **Label Description** sections.
2. For each label in the set, the label is written with the **EFI_NVDIMM_LABEL_FLAGS_UPDATING** flag set, using the flow outlined in **Writing New Labels** Description to its corresponding NVDIMM / Label Storage Area.
3. For each label in the set, the label is updated with the same contents as the previous step, but with the **EFI_NVDIMM_LABEL_FLAGS_UPDATING** flag clear, using the flow outlined in **Updating an Existing Label Description**.

In the case of an unexpected system interruption, the above flows leave either a partial set of labels, all with the new UUID, with the **EFI_NVDIMM_LABEL_FLAGS_UPDATING** flag set, or a complete set of labels is left where some of them have the **EFI_NVDIMM_LABEL_FLAGS_UPDATING** flag set. The recovery steps in Recovery Steps for a Non-Local Label Set Description comprehend these two cases so that software can determine whether the set is consistent or needs to be invalidated.

Creating a Local Namespace

Updating labels that are all on the same NVDIMM is atomic with respect to system interruption by nature of the Index Block update rules. Since Local namespaces reside on a single NVDIMM, the **EFI_NVDIMM_LABEL_FLAGS_UPDATING** flag and multi-pass update described in the previous section are not used. Software creating new Local namespaces shall follow these steps:

1. Pre-conditions: the labels to be written to the NVDIMM Label Storage Area have been constructed, whereby Position, **NLabel** and **SetCookie** adhere to the validation rules described earlier, and all labels share the same UUID. The Index Blocks involved have at least **NLabel + 1** label slots free, so that after the new labels are written, it will have at least 1 free label slot left.

All labels are written to free slots and made active in one step using steps similar to the flow described above in Writing New Labels Description:

a. Free slots are identified using the current Index Block, the **Slot** field in each label is updated accordingly

b. All new labels are written into their free slots

c. The new Index Block is constructed so the new label slots are no longer marked free, the sequence number is advanced as shown in **Figure Z: Cyclic Sequence Numbers in Label Index Block** in the **Seq** description, and then the new Index Block is written over the inactive Index Block location (making this location the new active Index Block if the write succeeds)

13.19.5.1 Updating the Name of a Namespace Description

Updating Local Labels

When updating the name on a Local set the sequence outlined in Writing New Labels Description must be followed where the Name is updated before writing the updated Label.

Updating Non Local Labels

To update the Name field associated with a non-Local Namespace, the software must follow these steps:

1. Pre-conditions: the namespace must already exist. Each NVDIMM in the namespace must have at least 1 free slot.

2. For each NVDIMM in the namespace, the label on that NVDIMM is updated with a label with the new Name field and the EFI_NVDIMM_LABEL_FLAGS_UPDATING flag set. The "for each NVDIMM " operation in this step must start with the NVDIMM containing the label whose Position field is zero.
3. For each NVDIMM in the namespace, the label is updated with the same contents as the previous step, but with the EFI_NVDIMM_LABEL_FLAGS_UPDATING flag clear, using the updating an existing label flow described above in Updating an Existing Label Description.

If the above steps are interrupted unexpectedly, the recovery steps in Recovery Steps for a Non-Local Label Set Description handle the case where a Name update is incomplete and finish the update.

13.20 EFI UFS Device Config Protocol

13.20.1 EFI_UFS_DEVICE_CONFIG_PROTOCOL

Summary

User invokes this protocol to access the UFS device descriptors/flags/attributes and configure UFS device behavior.

GUID

```
#define EFI_UFS_DEVICE_CONFIG_GUID \
  { 0xb81bfab0, 0xeb3, 0x4cf9, \
  { 0x84, 0x65, 0x7f, 0xa9, 0x86, 0x36, 0x16, 0x64}}
```

Protocol Interface Structure

```
typedef struct  _EFI_UFS_DEVICE_CONFIG_PROTOCOL {
  EFI_UFS_DEVICE_CONFIG_RW_DESCRIPTOR        RwUfsDescriptor;
  EFI_UFS_DEVICE_CONFIG_RW_FLAG              RwUfsFlag;
  EFI_UFS_DEVICE_CONFIG_RW_ATTRIBUTE         RwUfsAttribute;
} EFI_UFS_DEVICE_CONFIG_PROTOCOL;
```

Members

RwUfsDescriptor
Read or write specified device descriptor of a UFS device.

RwUfsFlag
Read or write specified flag of a UFS device.

RwUfsAttribute
Read or write specified attribute of a UFS device.

Description

This protocol aims at defining a standard interface for UEFI drivers and applications to access UFS device descriptors/flags/attributes and configure the UFS device behavior.

13.20.2 EFI_UFS_DEVICE_CONFIG_PROTOCOL.RwUfsDescriptor()

Summary

This function is used to read or write specified device descriptor of a UFS device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_UFS_DEVICE_CONFIG_RW_DESCRIPTOR) (
  IN EFI_UFS_DEVICE_CONFIG_PROTOCOL                *This,
  IN BOOLEAN                                       Read,
  IN UINT8                                         DescId,
  IN UINT8                                         Index,
  IN UINT8                                         Selector,
  IN OUT UINT8                                     Descriptor,
  IN OUT UINT32                                    *DescSize,
);
```

Parameters

This
The pointer to the EFI_UFS_DEVICE_CONFIG_PROTOCOL instance.

Read
The boolean variable to show r/w direction.

DescId
The ID of device descriptor.

Index
The Index of device descriptor.

Selector
The Selector of device descriptor.

Descriptor
The buffer of device descriptor to be read or written.

DescSize
The size of device descriptor buffer. On input, the size, in bytes, of the data buffer specified by Descriptor. On output, the number of bytes that were actually transferred.

Description

The RwUfsDescriptor function is used to read/write UFS device descriptors. The consumer of this API is responsible for allocating the data buffer pointed by Descriptor.

Status Codes Returned

EFI_SUCCESS	The device descriptor is read/written successfully.
EFI_INVALID_PARAMETER	This is NULL or Descriptor is NULL or DescSize is NULL.
EFI_INVALID_PARAMETER	DescId, Index and Selector are invalid combination to point to a type of UFS device descriptor.
EFI_DEVICE_ERROR	The device descriptor is not read/written successfully.

13.20.3 EFI_UFS_DEVICE_CONFIG_PROTOCOL.RwUfsFlag()

Summary

This function is used to read or write specified flag of a UFS device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_UFS_DEVICE_CONFIG_RW_FLAG) (
  IN EFI_UFS_DEVICE_CONFIG_PROTOCOL         *This,
  IN BOOLEAN                                Read,
  IN UINT8                                  FlagId,
  IN OUT UINT8                              *Flag,
);
```

Parameters

This
The pointer to the EFI_UFS_DEVICE_CONFIG_PROTOCOL instance.

Read
The boolean variable to show r/w direction.

FlagId
The ID of flag to be read or written.

Flag
The buffer to set or clear flag.

Description

The RwUfsFlag function is used to read/write UFS flag descriptors. The consumer of this API is responsible for allocating the buffer pointed by Flag. The buffer size is 1 byte as UFS flag descriptor is just a single Boolean value that represents a **TRUE** or **FALSE**, ‘0’ or ‘1’, ON or OFF type of value.

Status Codes Returned

EFI_SUCCESS	The flag descriptor is set/clear successfully.
EFI_INVALID_PARAMETER	This is NULL or Flag is NULL.
EFI_INVALID_PARAMETER	FlagId is an invalid UFS flag ID.
EFI_DEVICE_ERROR	The flag is not set/clear successfully.

13.20.4 EFI_UFS_DEVICE_CONFIG_PROTOCOL.RwUfsAttribute()

Summary

This function is used to read or write specified attribute of a UFS device.

Prototype

```
 typedef
EFI_STATUS
(EFIAPI *EFI_UFS_DEVICE_CONFIG_RW_ATTRIBUTE) (
  IN EFI_UFS_DEVICE_CONFIG_PROTOCOL            *This,
  IN BOOLEAN                                   Read,
```

(continues on next page)

(continued from previous page)

```
  IN UINT8                                      AttrId,
  IN UINT8                                      Index,
  IN UINT8                                      Selector,
  IN OUT UINT8                                  *Attribute,
  IN OUT UINT32                                 *AttrSize,
);
```

Parameters

This
The pointer to the EFI_UFS_DEVICE_CONFIG_PROTOCOL instance.

Read
The boolean variable to show r/w direction.

AttrId
The ID of Attribute.

Index
The Index of Attribute.

Selector
The Selector of Attribute.

Attribute
The buffer of Attribute to be read or written.

AttrSize
The size of Attribute buffer. On input, the size, in bytes, of the data buffer specified by Attribute. On output, the number of bytes that were actually transferred.

Description

The *RwUfsAttribute* function is used to read/write UFS attributes. The consumer of this API is responsible for allocating the data buffer pointed by *Attribute*.

Status Codes Returned

EFI_SUCCESS	The attribute is read/written successfully.
EFI_INVALID_PARAMETER	This is NULL or Attribute is NULL or AttrSize is NULL.
EFI_INVALID_PARAMETER	AttrId, Index and Selector are invalid combination to point to a type of UFS attribute.
EFI_DEVICE_ERROR	The attribute is not read/written successfully.

CHAPTER

FOURTEEN

PROTOCOLS — PCI BUS SUPPORT

14.1 PCI Root Bridge I/O Support

This section and the following one (Section 14.2) describe the PCI Root Bridge I/O Protocol. This protocol provides an I/O abstraction for a PCI Root Bridge that is produced by a PCI Host Bus Controller. A PCI Host Bus Controller is a hardware component that allows access to a group of PCI devices that share a common pool of PCI I/O and PCI Memory resources. This protocol is used by a PCI Bus Driver to perform PCI Memory, PCI I/O, and PCI Configuration cycles on a PCI Bus. It also provides services to perform different types of bus mastering DMA on a PCI bus. PCI device drivers will not directly use this protocol. Instead, they will use the I/O abstraction produced by the PCI Bus Driver. Only drivers that require direct access to the entire PCI bus should use this protocol. In particular, this chapter defines functions for managing PCI buses, although other bus types may be supported in a similar fashion as extensions to this specification.

All the services described in this chapter that generate PCI transactions follow the ordering rules defined in the PCI Specification. If the processor is performing a combination of PCI transactions and system memory transactions, then there is no guarantee that the system memory transactions will be strongly ordered with respect to the PCI transactions. If strong ordering is required, then processor-specific mechanisms may be required to guarantee strong ordering. Some 64-bit systems may require the use of memory fences to guarantee ordering.

14.1.1 PCI Root Bridge I/O Overview

The interfaces provided in the *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL* are for performing basic operations to memory, I/O, and PCI configuration space. The system provides abstracted access to basic system resources to allow a driver to have a programmatic method to access these basic system resources.

The *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL* allows for future innovation of the platform. It abstracts device-specific code from the system memory map. This allows system designers to make changes to the system memory map without impacting platform independent code that is consuming basic system resources.

A platform can be viewed as a set of processors and a set of core chipset components that may produce one or more host buses. Figure *Host Bus Controllers* shows a platform with *n* processors (CPUs in the figure), and a set of core chipset components that produce *m* host bridges.

Simple systems with one PCI Host Bus Controller will contain a single instance of the *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL*. More complex system may contain multiple instances of this protocol. It is important to note that there is no relationship between the number of chipset components in a platform and the number of *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL* instances. This protocol abstracts access to a PCI Root Bridge from a software point of view, and it is attached to a device handle that represents a PCI Root Bridge. A PCI Root Bridge is a chipset component(s) that produces a physical PCI Bus. It is also the parent to a set of PCI devices that share common PCI I/O, PCI Memory, and PCI Prefetchable Memory regions. A PCI Host Bus Controller is composed of one or more PCI Root Bridges.

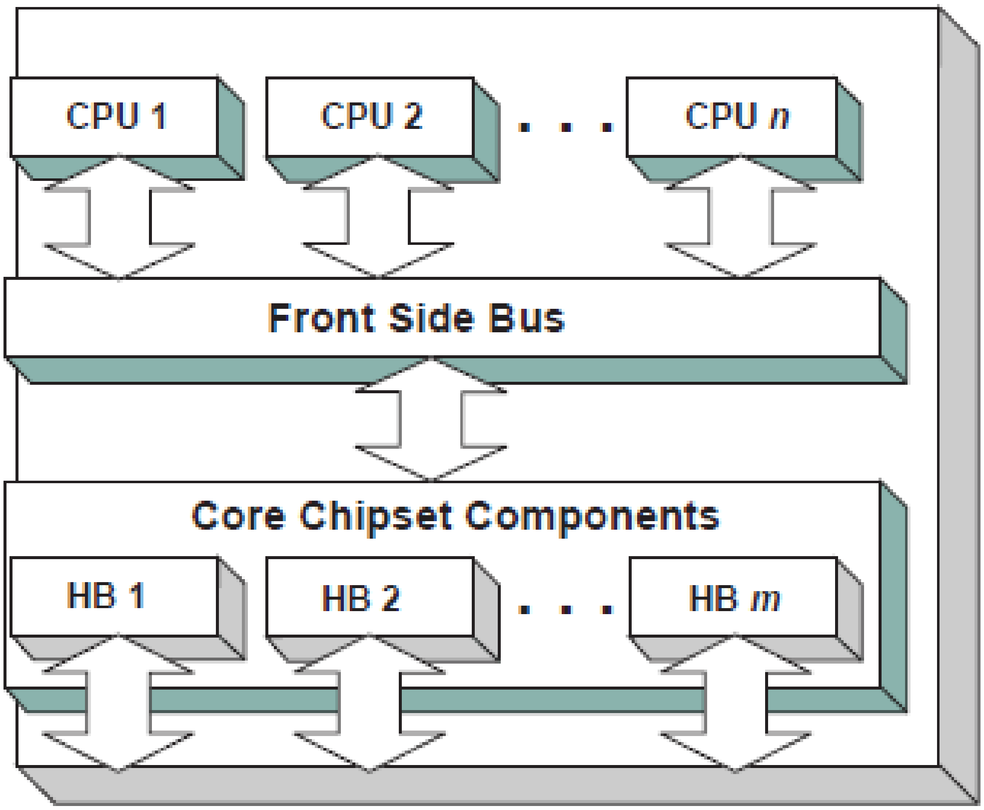

Fig. 14.1: **Host Bus Controllers**

A PCI Host Bridge and PCI Root Bridge are different than a PCI Segment. A PCI Segment is a collection of up to 256 PCI busses that share the same PCI Configuration Space. Depending on the chipset, a single *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL* may abstract a portion of a PCI Segment, or an entire PCI Segment. A PCI Host Bridge may produce one or more PCI Root Bridges. When a PCI Host Bridge produces multiple PCI Root Bridges, it is possible to have more than one PCI Segment.

PCI Root Bridge I/O Protocol instances are either produced by the system firmware or by a UEFI driver. When a PCI Root Bridge I/O Protocol is produced, it is placed on a device handle along with an EFI Device Path Protocol instance. The figure below (*Device Handle for a PCI Root Bridge Controller*) shows a sample device handle that includes an instance of the EFI_DEVICE_PATH_PROTOCOL and the EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.

Section Section 14.2 describes the PCI Root Bridge I/O Protocol in detail, and Section 14.2.19 describes how to build device paths for PCI Root Bridges. The EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL does not abstract access to the chipset-specific registers used to manage a PCI Root Bridge. This functionality is hidden within the system firmware or the driver that produces the handles that represent the PCI Root Bridges.

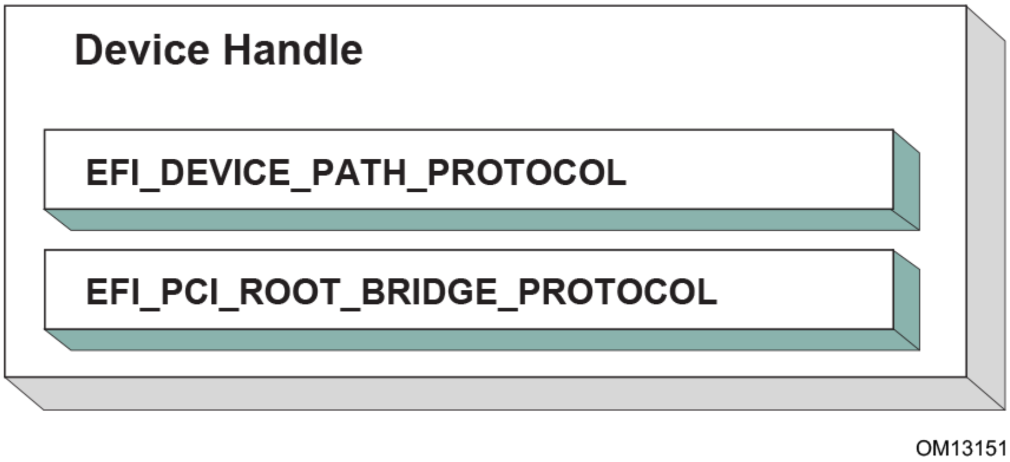

Fig. 14.2: Device Handle for a PCI Root Bridge Controller

14.1.2 Sample PCI Architectures

The PCI Root Bridge I/O Protocol is designed to provide a software abstraction for a wide variety of PCI architectures including the ones described in this section. This section is not intended to be an exhaustive list of the PCI architectures that the PCI Root Bridge I/O Protocol can support. Instead, it is intended to show the flexibility of this protocol to adapt to current and future platform designs.

See *Desktop System with One PCI Root Bridge* shows an example of a PCI Host Bus with one PCI Root Bridge. This PCI Root Bridge produces one PCI Local Bus that can contain PCI Devices on the motherboard and/or PCI slots. This would be typical of a desktop system. A higher end desktop system might contain a second PCI Root Bridge for AGP devices. The firmware for this platform would produce one instance of the PCI Root Bridge I/O Protocol.

Figure *Server System with Four PCI Root Bridges* shows an example of a larger server with one PCI Host Bus and four PCI Root Bridges. The PCI devices attached to the PCI Root Bridges are all part of the same coherency domain. This means they share a common PCI I/O Space, a common PCI Memory Space, and a common PCI Prefetchable Memory Space. Each PCI Root Bridge produces one PCI Local Bus that can contain PCI Devices on the motherboard or PCI slots. The firmware for this platform would produce four instances of the PCI Root Bridge I/O Protocol.

The Figure *Server System with Two PCI Segments* , below, shows an example of a server with one PCI Host Bus and two PCI Root Bridges. Each of these PCI Root Bridges is a different PCI Segment which allows the system to have up to 512 PCI Buses. A single PCI Segment is limited to 256 PCI Buses. These two segments do not share the same PCI

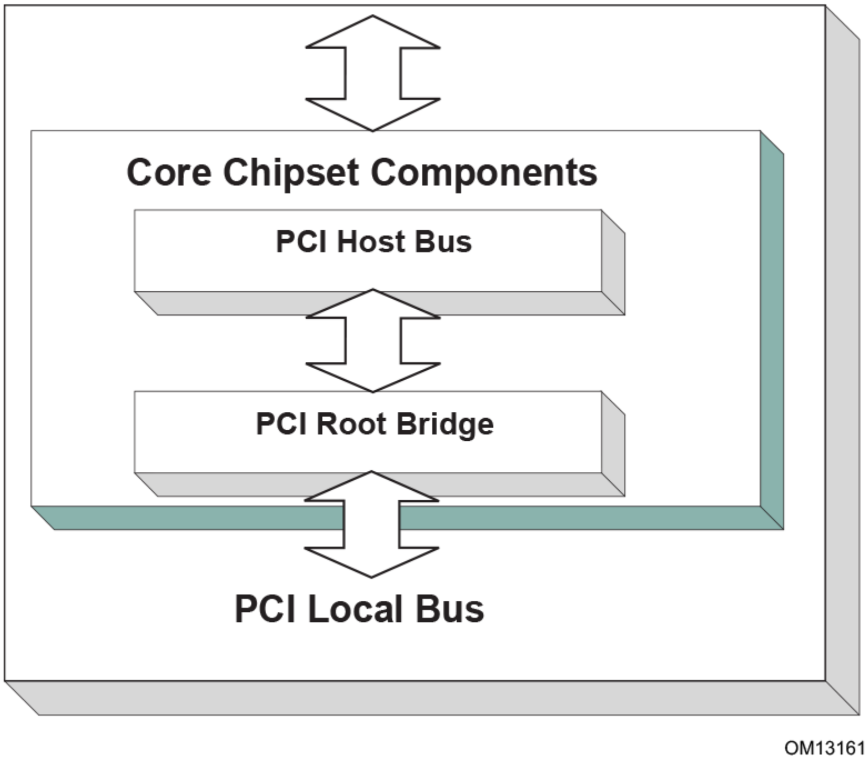

Fig. 14.3: **Desktop System with One PCI Root Bridge**

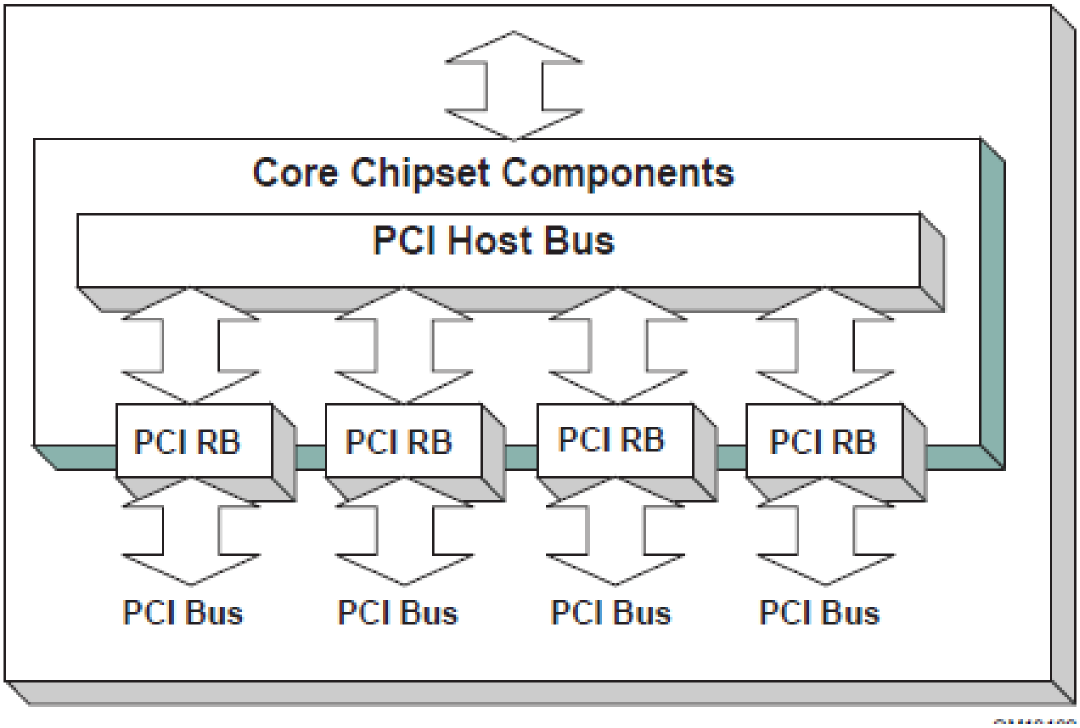

Fig. 14.4: **Server System with Four PCI Root Bridges**

Configuration Space, but they do share the same PCI I/O, PCI Memory, and PCI Prefetchable Memory Space. This is why it can be described by a single PCI Host Bus. The firmware for this platform would produce two instances of the PCI Root Bridge I/O Protocol.

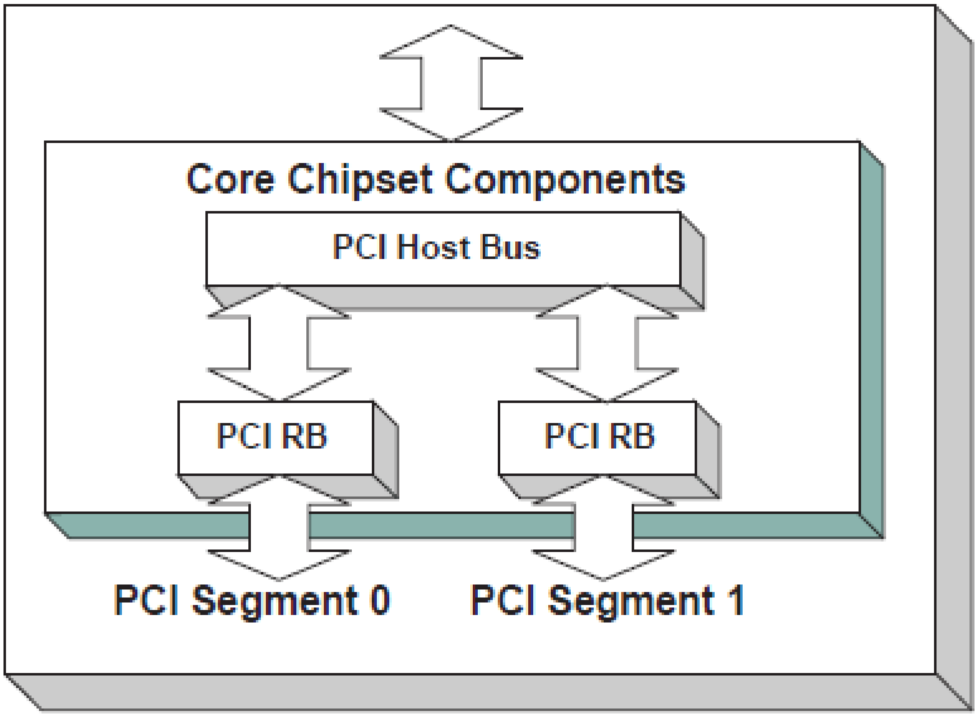

Fig. 14.5: Server System with Two PCI Segments

The Figure, *Server System with Two PCI Host Buses* , below, shows a server system with two PCI Host Buses and one PCI Root Bridge per PCI Host Bus. This system supports up to 512 PCI Buses, but the PCI I/O, PCI Memory Space, and PCI Prefetchable Memory Space are not shared between the two PCI Root Bridges. The firmware for this platform would produce two instances of the PCI Root Bridge I/O Protocol.

14.2 PCI Root Bridge I/O Protocol

This section provides detailed information on the PCI Root Bridge I/O Protocol and its functions.

14.2.1 EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL

Summary

Provides the basic Memory, I/O, PCI configuration, and DMA interfaces that are used to abstract accesses to PCI controllers behind a PCI Root Bridge Controller.

GUID

```
#define EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_GUID \
  {0x2F707EBB,0x4A1A,0x11d4,\
    {0x9A,0x38,0x00,0x90,0x27,0x3F,0xC1,0x4D}}
```

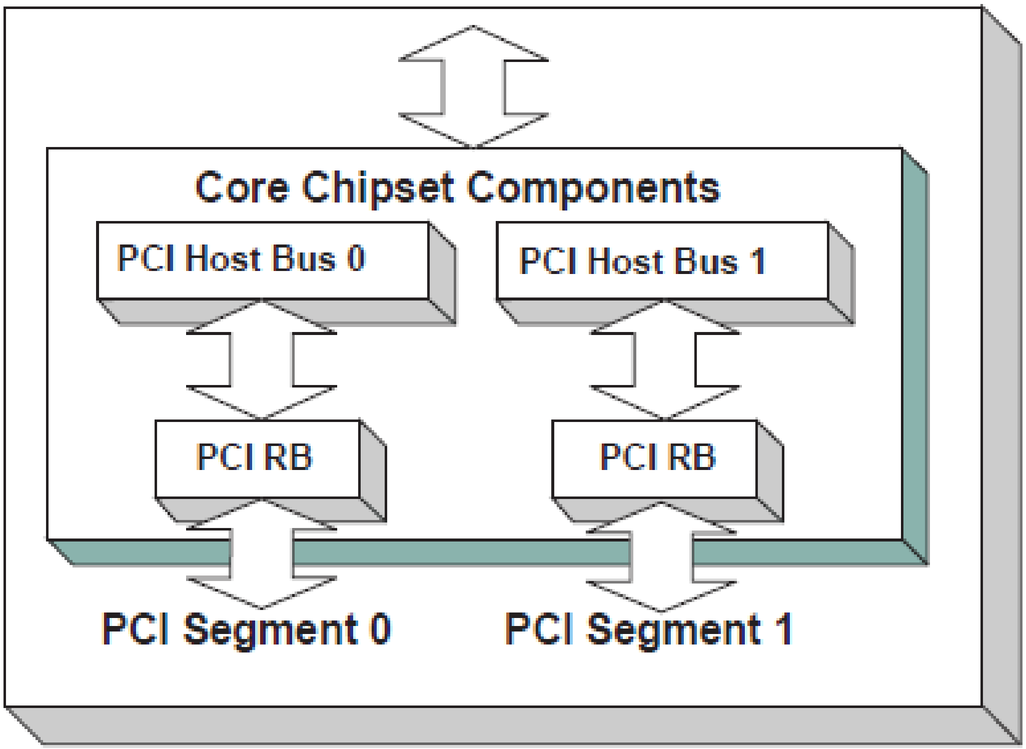

Fig. 14.6: Server System with Two PCI Host Buses

Protocol Interface Structure

```
typedef struct _EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL {
  EFI_HANDLE
 ParentHandle;
  EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_POLL_IO_MEM      PollMem;
  EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_POLL_IO_MEM      PollIo;
  EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_ACCESS           Mem;
  EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_ACCESS           Io;

  EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_GET_ATTRIBUTES   GetAttributes;
  EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_SET_ATTRIBUTES   SetAttributes;
  EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_CONFIGURATION    Configuration;
  UINT32                                           SegmentNumber;
}   EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL;
```

Parameters

ParentHandle

The EFI_HANDLE of the PCI Host Bridge of which this PCI Root Bridge is a member.

PollMem
Polls an address in memory mapped I/O space until an exit condition is met, or a timeout occurs. See the *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.PollMem()* function description .

PollIo
Polls an address in I/O space until an exit condition is met, or a timeout occurs. See the *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.PollIo()* function description.

Mem.Read
Allows reads from memory mapped I/O space. See the Mem.Read() *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.Mem.Read()* function description.

Mem.Write
Allows writes to memory mapped I/O space. See the Mem.Write() *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.Mem.Write()* function description.

Io.Read
Allows reads from I/O space. See the Io.Read() *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.Io.Read()* function description.

Io.Write
Allows writes to I/O space. See the Io.Write() *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.Io.WRITE()* function description.

Pci.Read
Allows reads from PCI configuration space. See the Pci.Read() *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.Pci.Read()* function description.

Pci.Write
Allows writes to PCI configuration space. See the Pci.Write() *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.Pci.Write()* function description.

CopyMem
Allows one region of PCI root bridge memory space to be copied to another region of PCI root bridge memory space. See the *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.CopyMem()* function description.

Map
Provides the PCI controller-specific addresses needed to access system memory for DMA. See the *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.Map()* function description.

Unmap
Releases any resources allocated by Map(). See the *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.Unmap()* function description.

AllocateBuffer
Allocates pages that are suitable for a common buffer mapping. See the *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.AllocateBuffer()* function description.

FreeBuffer
Free pages that were allocated with AllocateBuffer(). See the *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.FreeBuffer()* function description.

Flush
Flushes all PCI posted write transactions to system memory. See the *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.Flush()* function description.

GetAttributes
Gets the attributes that a PCI root bridge supports setting with *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.SetAttributes()* , and the attributes that a PCI root bridge is currently using. See the *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.GetAttributes()* function description.

SetAttributes

Sets attributes for a resource range on a PCI root bridge. See *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.SetAttributes()* function description.

Configuration

Gets the current resource settings for this PCI root bridge. See the *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.Configuration()* function description.

SegmentNumber

The segment number that this PCI root bridge resides.

```

EFI_PCI_ATTRIBUTE_ISA_IO_16

If this bit is set, then the PCI I/O cycles between 0x100 and 0x3FF are forwarded onto a PCI root bridge using a 16-bit address decoder on address bits 0..15. Address bits 16..31 must be zero. This bit is used to forward I/O cycles for legacy ISA devices onto a PCI root bridge. This bit may not be combined with *EFI_PCI_ATTRIBUTE_ISA_IO*.

EFI_PCI_ATTRIBUTE_VGA_PALETTE_IO_16

If this bit is set, then the PCI I/O write cycles for 0x3C6, 0x3C8, and 0x3C9 are forwarded onto a PCI root bridge using a 16-bit address decoder on address bits 0..15. Address bits 16..31 must be zero. This bit is used to forward I/O write cycles to the VGA palette registers onto a PCI root bridge. This bit may not be combined with *EFI_PCI_ATTRIBUTE_VGA_IO* or *EFI_PCI_ATTRIBUTE_VGA_PALETTE_IO*.

EFI_PCI_ATTRIBUTE_VGA_IO_16

If this bit is set, then the PCI I/O cycles in the ranges 0x3B0-0x3BB and 0x3C0-0x3DF are forwarded onto a PCI root bridge using a 16-bit address decoder on address bits 0..15. Address bits 16..31 must be zero. This bit is used to forward I/O cycles for a VGA controller onto a PCI root bridge. This bit may not be combined with *EFI_PCI_ATTRIBUTE_VGA_IO* or *EFI_PCI_ATTRIBUTE_VGA_PALETTE_IO*. Because *EFI_PCI_ATTRIBUTE_VGA_IO_16* also includes the I/O range described by *EFI_PCI_ATTRIBUTE_VGA_PALETTE_IO_16* , the *EFI_PCI_ATTRIBUTE_VGA_PALETTE_IO_16* bit is ignored if *EFI_PCI_ATTRIBUTE_VGA_IO_16* is set.

EFI_PCI_ATTRIBUTE_ISA_MOTHERBOARD_IO

If this bit is set, then the PCI I/O cycles between 0x00000000 and 0x000000FF are forwarded onto a PCI root bridge. This bit is used to forward I/O cycles for ISA motherboard devices onto a PCI root bridge.

EFI_PCI_ATTRIBUTE_ISA_IO

If this bit is set, then the PCI I/O cycles between 0x100 and 0x3FF are forwarded onto a PCI root bridge using a 10-bit address decoder on address bits 0..9. Address bits 10..15 are not decoded, and address bits 16..31 must be zero. This bit is used to forward I/O cycles for legacy ISA devices onto a PCI root bridge.

EFI_PCI_ATTRIBUTE_VGA_PALETTE_IO

If this bit is set, then the PCI I/O write cycles for 0x3C6, 0x3C8, and 0x3C9 are forwarded onto a PCI root bridge using a 10 bit address decoder on address bits 0..9. Address bits 10..15 are not decoded, and address bits 16..31 must be zero. This bit is used to forward I/O write cycles to the VGA palette registers onto a PCI root bridge.

EFI_PCI_ATTRIBUTE_VGA_MEMORY

If this bit is set, then the PCI memory cycles between 0xA0000 and 0xBFFFF are forwarded onto a PCI root bridge. This bit is used to forward memory cycles for a VGA frame buffer onto a PCI root bridge.

EFI_PCI_ATTRIBUTE_VGA_IO

If this bit is set, then the PCI I/O cycles in the ranges 0x3B0-0x3BB and 0x3C0-0x3DF are forwarded onto a PCI root bridge using a 10-bit address decoder on address bits 0..9. Address bits 10..15 are not decoded, and the address bits 16..31 must be zero. This bit is used to forward I/O cycles for a VGA controller onto a PCI root bridge. Since EFI_PCI_ATTRIBUTE_ENABLE_VGA_IO also includes the I/O range described by EFI_PCI_ATTRIBUTE_ENABLE_VGA_PALETTE_IO, the EFI_PCI_ATTRIBUTE_ENABLE_VGA_PALETTE_IO bit is ignored if EFI_PCI_ATTRIBUTE_ENABLE_VGA_IO is set.

EFI_PCI_ATTRIBUTE_IDE_PRIMARY_IO

If this bit is set, then the PCI I/O cycles in the ranges 0x1F0-0x1F7 and 0x3F6-0x3F7 are forwarded onto a PCI root bridge using a 16-bit address decoder on address bits 0..15. Address bits 16..31 must be zero. This bit is used to forward I/O cycles for a Primary IDE controller onto a PCI root bridge.

EFI_PCI_ATTRIBUTE_IDE_SECONDARY_IO

If this bit is set, then the PCI I/O cycles in the ranges 0x170-0x177 and 0x376-0x377 are forwarded onto a PCI root bridge using a 16-bit address decoder on address bits 0..15. Address bits 16..31 must be zero. This bit is used to forward I/O cycles for a Secondary IDE controller onto a PCI root bridge.

EFI_PCI_ATTRIBUTE_MEMORY_WRITE_COMBINE

If this bit is set, then this platform supports changing the attributes of a PCI memory range so that the memory range is accessed in a write combining mode. By default, PCI memory ranges are not accessed in a write combining mode.

EFI_PCI_ATTRIBUTE_MEMORY_CACHED

If this bit is set, then this platform supports changing the attributes of a PCI memory range so that the memory range is accessed in a cached mode. By default, PCI memory ranges are accessed noncached.

EFI_PCI_ATTRIBUTE_MEMORY_DISABLE

If this bit is set, then this platform supports changing the attributes of a PCI memory range so that the memory range is disabled, and can no longer be accessed. By default, all PCI memory ranges are enabled.

EFI_PCI_ATTRIBUTE_DUAL_ADDRESS_CYCLE

This bit may only be used in the Attributes parameter to *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.AllocateBuffer()*. If this bit is set, then the PCI controller that is requesting a buffer through AllocateBuffer() is capable of producing PCI Dual Address Cycles, so it is able to access a 64-bit address space. If this bit is not set, then the PCI controller that is requesting a buffer through AllocateBuffer() is not capable of producing PCI Dual Address Cycles, so it is only able to access a 32-bit address space.

```
//*******************************************************
// EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_OPERATION
```

(continues on next page)

  EfiPciOperationBusMasterWrite,
  EfiPciOperationBusMasterCommonBuffer,
  EfiPciOperationBusMasterRead64,
  EfiPciOperationBusMasterWrite64,
  EfiPciOperationBusMasterCommonBuffer64,
  EfiPciOperationMaximum
}  EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_OPERATION;
```

EfiPciOperationBusMasterRead
A read operation from system memory by a bus master that is not capable of producing PCI dual address cycles.

EfiPciOperationBusMasterWrite
A write operation to system memory by a bus master that is not capable of producing PCI dual address cycles.

EfiPciOperationBusMasterCommonBuffer
Provides both read and write access to system memory by both the processor and a bus master that is not capable of producing PCI dual address cycles. The buffer is coherent from both the processor's and the bus master's point of view.

EfiPciOperationBusMasterRead64
A read operation from system memory by a bus master that is capable of producing PCI dual address cycles.

EfiPciOperationBusMasterWrite64
A write operation to system memory by a bus master that is capable of producing PCI dual address cycles.

EfiPciOperationBusMasterCommonBuffer64
Provides both read and write access to system memory by both the processor and a bus master that is capable of producing PCI dual address cycles. The buffer is coherent from both the processor's and the bus master's point of view.

Description

The *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL* provides the basic Memory, I/O, PCI configuration, and DMA interfaces that are used to abstract accesses to PCI controllers. There is one *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL* instance for each PCI root bridge in a system. Embedded systems, desktops, and workstations will typically only have one PCI root bridge. High-end servers may have multiple PCI root bridges. A device driver that wishes to manage a PCI bus in a system will have to retrieve the *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL* instance that is associated with the PCI bus to be managed. A device handle for a PCI Root Bridge will minimally contain an *EFI Device Path Protocol* instance and an *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL* instance. The PCI bus driver can look at the *EFI_DEVICE_PATH_PROTOCOL* instances to determine which *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL* instance to use.

Bus mastering PCI controllers can use the DMA services for DMA operations. There are three basic types of bus mastering DMA that is supported by this protocol. These are DMA reads by a bus master, DMA writes by a bus master, and common buffer DMA. The DMA read and write operations may need to be broken into smaller chunks. The caller of *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.Map()* must pay attention to the number of bytes that were mapped, and if required, loop until the entire buffer has been transferred. The following is a list of the different bus mastering DMA operations that are supported, and the sequence of *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL* APIs that are used for each DMA operation type. See "Related Definitions" above for the definition of the different DMA operation types.

DMA Bus Master Read Operation

- Call *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.Map()* for EfiPciOperationBusMasterRead or EfiPciOperationBusMasterRead64.

- Program the DMA Bus Master with the DeviceAddress returned by Map().
- Start the DMA Bus Master.
- Wait for DMA Bus Master to complete the read operation.
- Call *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.Unmap()*

DMA Bus Master Write Operation

- Call *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.Map()* for EfiPciOperationBusMasterWrite or EfiPciOperationBusMasterRead64.
- Program the DMA Bus Master with the DeviceAddress returned by *EFI_PCI_IO_PROTOCOL.Map()*
- Start the DMA Bus Master.
- Wait for DMA Bus Master to complete the write operation.
- Perform a PCI controller specific read transaction to flush all PCI write buffers (See PCI Specification Section 3.2.5.2).
- Call *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.Flush()*
- Call Unmap.

DMA Bus Master Common Buffer Operation

- Call *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.AllocateBuffer()* to allocate a common buffer.
- Call Map() for EfiPciOperationBusMasterCommonBuffer or EfiPciOperationBusMasterCommonBuffer64.
- Program the DMA Bus Master with the DeviceAddress returned by *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.Map()* .
- The common buffer can now be accessed equally by the processor and the DMA bus master.
- Call Unmap().
- Call *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.FreeBuffer()* .

14.2.2 EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.PollMem()

Summary

Reads from the memory space of a PCI Root Bridge. Returns when either the polling exit criteria is satisfied or after a defined duration.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_POLL_IO_MEM) (
  IN EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL             *This,
  IN EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_WIDTH       Width,
  IN UINT64                                      Address,
  IN UINT64                                      Mask,
  IN UINT64                                      Value,
  IN UINT64                                      Delay,
  OUT UINT64                                     *Result
  );
```

Parameters

This

A pointer to the *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL*. Type EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL is defined in the Section *PCI Root Bridge I/O Protocol* .

Width

Signifies the width of the memory operations. Type EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_WIDTH see **Related Definitions** in the section *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL* .

Address

The base address of the memory operations. The caller is responsible for aligning Address if required.

Mask

Mask used for the polling criteria. Bytes above Width in Mask are ignored. The bits in the bytes below Width which are zero in Mask are ignored when polling the memory address.

Value

The comparison value used for the polling exit criteria.

Delay

The number of 100 ns units to poll. Note that timer available may be of poorer granularity.

Result

Pointer to the last value read from the memory location.

Description

This function provides a standard way to poll a PCI memory location. A PCI memory read operation is performed at the PCI memory address specified by *Address* for the width specified by *Width*. The result of this PCI memory read operation is stored in *Result*. This PCI memory read operation is repeated until either a timeout of *Delay* 100 ns units has expired, or (*Result* & *Mask)* is equal to *Value*.

This function will always perform at least one PCI memory read access no matter how small *Delay* may be. If *Delay* is zero, then *Result* will be returned with a status of *EFI_SUCCESS* even if *Result* does not match the exit criteria. If *Delay* expires, then *EFI_TIMEOUT* is returned.

If *Width* is not *EfiPciWidthUint8* , *EfiPciWidthUint16* , *EfiPciWidthUint32* , or *EfiPciWidthUint64* , then *EFI_INVALID_PARAMETER* is returned.

The memory operations are carried out exactly as requested. The caller is responsible for satisfying any alignment and memory width restrictions that a PCI Root Bridge on a platform might require. For example on some platforms, width requests of EfiPciWidthUint64 are not supported.

All the PCI transactions generated by this function are guaranteed to be completed before this function returns. However, if the memory mapped I/O region being accessed by this function has the EFI_PCI_ATTRIBUTE_MEMORY_CACHED attribute set, then the transactions will follow the ordering rules defined by the processor architecture.

Status Codes Returned

EFI_SUCCESS	The last data returned from the access matched the poll exit criteria.
EFI_INVALID_PARAMETER	Width is invalid.
EFI_INVALID_PARAMETER	Result is **NULL**.
EFI_TIMEOUT	Delay expired before a match occurred.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.

14.2.3 EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.PollIo()

Summary

Reads from the I/O space of a PCI Root Bridge. Returns when either the polling exit criteria is satisfied or after a defined duration.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_POLL_IO_MEM) (
  IN EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL           *This,
  IN EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_WIDTH     Width,
  IN UINT64                                    Address,
  IN UINT64                                    Mask,
  IN UINT64                                    Value,
  IN UINT64                                    Delay,
  OUT UINT64                                   *Result
  );
```

Parameters

This
A pointer to the *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL*. Type EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL is defined in *PCI Root Bridge I/O Protocol* .

Width
Signifies the width of the I/O operations. Type EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_WIDTH see **Related Definitions** in the section *PCI Root Bridge I/O Protocol* .

Address
The base address of the I/O operations. The caller is responsible for aligning Address if required.

Mask
Mask used for the polling criteria. Bytes above Width in Mask are ignored. The bits in the bytes below Width which are zero in Mask are ignored when polling the I/O address.

Value
The comparison value used for the polling exit criteria.

Delay
The number of 100 ns units to poll. Note that timer available may be of poorer granularity.

Result
Pointer to the last value read from the memory location.

Description

This function provides a standard way to poll a PCI I/O location. A PCI I/O read operation is performed at the PCI I/O address specified by *Address* for the width specified by *Width*. The result of this PCI I/O read operation is stored in *Result*. This PCI I/O read operation is repeated until either a timeout of *Delay* 100 ns units has expired, or (*Result & Mask*) is equal to *Value*.

This function will always perform at least one I/O access no matter how small *Delay* may be. If *Delay* is zero, then *Result* will be returned with a status of *EFI_SUCCESS* even if *Result* does not match the exit criteria. If *Delay* expires, then *EFI_TIMEOUT* is returned.

If *Width* is not *EfiPciWidthUint8* , *EfiPciWidthUint16* , *EfiPciWidthUint32* , or *EfiPciWidthUint64* , then *EFI_INVALID_PARAMETER* is returned.

The I/O operations are carried out exactly as requested. The caller is responsible satisfying any alignment and I/O width restrictions that the PCI Root Bridge on a platform might require. For example on some platforms, width requests of *EfiPciWidthUint64* do not work.

All the PCI transactions generated by this function are guaranteed to be completed before this function returns.

Status Codes Returned

EFI_SUCCESS	The last data returned from the access matched the poll exit criteria.
EFI_INVALID_PARAMETER	Width is invalid.
EFI_INVALID_PARAMETER	Result is *NULL*.
EFI_TIMEOUT	Delay expired before a match occurred.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.

14.2.4 EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.Mem.Read()

14.2.5 EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.Mem.Write()

Summary

Enables a PCI driver to access PCI controller registers in the PCI root bridge memory space.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_IO_MEM) (
  IN EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL                  *This,
  IN EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_WIDTH            Width,
  IN UINT64                                           Address,
  IN UINTN                                            Count,
  IN OUT VOID                                         *Buffer
  );
```

Parameters

This

A pointer to the *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL*. Type EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL is defined in *PCI Root Bridge I/O Protocol* .

Width

Signifies the width of the memory operation. Type EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_WIDTH see **Related Definitions** in the section *PCI Root Bridge I/O Protocol* .

Address

The base address of the memory operation. The caller is responsible for aligning the Address if required.

Count

The number of memory operations to perform. Bytes moved is Width size * Count, starting at Address.

Buffer

For read operations, the destination buffer to store the results. For write operations, the source buffer to write data from.

Description

The *Mem.Read()* , and *Mem.Write()* functions enable a driver to access PCI controller registers in the PCI root bridge memory space.

The memory operations are carried out exactly as requested. The caller is responsible for satisfying any alignment and memory width restrictions that a PCI Root Bridge on a platform might require. For example on some platforms, width requests of *EfiPciWidthUint64* do not work.

If *Width* is *EfiPciWidthUint8* , *EfiPciWidthUint16* , *EfiPciWidthUint32* , or *EfiPciWidthUint64* , then both *Address* and *Buffer* are incremented for each of the *Count* operations performed.

If *Width* is *EfiPciWidthFifoUint8* , *EfiPciWidthFifoUint16* , *EfiPciWidthFifoUint32* , or *EfiPciWidthFifoUint64* , then only *Buffer* is incremented for each of the *Count* operations performed. The read or write operation is performed *Count* times on the same *Address*.

If *Width* is *EfiPciWidthFillUint8* , *EfiPciWidthFillUint16* , *EfiPciWidthFillUint32* , or *EfiPciWidthFillUint64* , then only *Address* is incremented for each of the *Count* operations performed. The read or write operation is performed *Count* times from the first element of *Buffer*.

All the PCI read transactions generated by this function are guaranteed to be completed before this function returns. All the PCI write transactions generated by this function will follow the write ordering and completion rules defined in the PCI Specification. However, if the memory-mapped I/O region being accessed by this function has the *EFI_PCI_ATTRIBUTE_MEMORY_CACHED* attribute set, then the transactions will follow the ordering rules defined by the processor architecture.

Status Codes Returned

EFI_SUCCESS	The data was read from or written to the PCI root bridge.
EFI_INVALID_PARAMETER	Width is invalid for this PCI root bridge.
EFI_INVALID_PARAMETER	Buffer is *NULL*.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.

14.2.6 EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.Io.Read()

14.2.7 EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.Io.Write()

Summary

Enables a PCI driver to access PCI controller registers in the PCI root bridge I/O space.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_IO_MEM) (
  IN EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL             *This,
  IN EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_WIDTH       Width,
  IN UINT64                                      Address,
  IN UINTN                                       Count,
  IN OUT VOID                                    *Buffer
  );
```

Parameters

This
A pointer to the *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL*. Type EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL is defined in *PCI Root Bridge I/O Protocol* .

Width
Signifies the width of the memory operation. Type EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_WIDTH see **Related Definitions** in the section *PCI Root Bridge I/O Protocol* .

Address
The base address of the I/O operation. The caller is responsible for aligning the Address if required.

Count
The number of I/O operations to perform. Bytes moved is Width size * Count, starting at Address.

Buffer
For read operations, the destination buffer to store the results. For write operations, the source buffer to write data from.

Description

The *Io.Read()* , and *Io.Write()* functions enable a driver to access PCI controller registers in the PCI root bridge I/O space.

The I/O operations are carried out exactly as requested. The caller is responsible for satisfying any alignment and I/O width restrictions that a PCI root bridge on a platform might require. For example on some platforms, width requests of *EfiPciWidthUint64* do not work.

If *Width* is *EfiPciWidthUint8* , *EfiPciWidthUint16* , *EfiPciWidthUint32* , or *EfiPciWidthUint64* , then both *Address* and *Buffer* are incremented for each of the *Count* operations performed.

If *Width* is *EfiPciWidthFifoUint8* , *EfiPciWidthFifoUint16* , *EfiPciWidthFifoUint32* , or *EfiPciWidthFifoUint64* , then only *Buffer* is incremented for each of the *Count* operations performed. The read or write operation is performed *Count* times on the same *Address*.

If *Width* is *EfiPciWidthFillUint8* , *EfiPciWidthFillUint16* , *EfiPciWidthFillUint32* , or *EfiPciWidthFillUint64* , then only *Address* is incremented for each of the *Count* operations performed. The read or write operation is performed *Count* times from the first element of *Buffer*.

All the PCI transactions generated by this function are guaranteed to be completed before this function returns.

Status Codes Returned

EFI_SUCCESS	The data was read from or written to the PCI root bridge.
EFI_INVALID_PARAMETER	Width is invalid for this PCI root bridge.
EFI_INVALID_PARAMETER	Buffer is *NULL*.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.

14.2.8 EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.Pci.Read()

14.2.9 EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.Pci.Write()

Summary

Enables a PCI driver to access PCI controller registers in a PCI root bridge's configuration space.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_IO_MEM) (
  IN EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL              *This,
  IN EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_WIDTH        Width,
  IN UINT64                                       Address,
  IN UINTN                                        Count,
  IN OUT VOID                                     *Buffer
  );
```

Parameters

This
A pointer to the *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL*. Type EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL is defined in *PCI Root Bridge I/O Protocol* .

Width
Signifies the width of the memory operation. Type EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_WIDTH see **Related Definitions** in the section *PCI Root Bridge I/O Protocol* .

Address
The address within the PCI configuration space for the PCI controller. See *PCI Configuration Address* for the format of Address.

Count
The number of PCI configuration operations to perform. Bytes moved is Width size * Count, starting at Address.

Buffer
For read operations, the destination buffer to store the results. For write operations, the source buffer to write data from.

Description

The *Pci.Read()* and *Pci.Write()* functions enable a driver to access PCI configuration registers for a PCI controller.

The PCI Configuration operations are carried out exactly as requested. The caller is responsible for any alignment and PCI configuration width issues that a PCI Root Bridge on a platform might require. For example on some platforms, width requests of *EfiPciWidthUint64* do not work.

If *Width* is *EfiPciWidthUint8* , *EfiPciWidthUint16* , *EfiPciWidthUint32* , or *EfiPciWidthUint64* , then both *Address* and *Buffer* are incremented for each of the *Count* operations performed.

If *Width* is *EfiPciWidthFifoUint8* , *EfiPciWidthFifoUint16* , *EfiPciWidthFifoUint32* , or *EfiPciWidthFifoUint64* , then only *Buffer* is incremented for each of the *Count* operations performed. The read or write operation is performed *Count* times on the same *Address*.

If *Width* is *EfiPciWidthFillUint8*, *EfiPciWidthFillUint16*, *EfiPciWidthFillUint32*, or *EfiPciWidthFillUint64*, then only Address is incremented for each of the Count operations performed. The read or write operation is performed *Count* times from the first element of *Buffer*.

All the PCI transactions generated by this function are guaranteed to be completed before this function returns.

Table 14.5: PCI Configuration Address

Mnemonic	Byte Offset	Byte Length	Description
Register	0	1	The register number on the PCI Function.
Function	1	1	The PCI Function number on the PCI Device.
Device	2	1	The PCI Device number on the PCI Bus.

continues on next page

Table 14.5 – continued from previous page

Bus	3	1	The PCI Bus number.
ExtendedRegister	4	4	The register number on the PCI Function. If this field is zero, then the Register field is used for the register number. If this field is nonzero, then the Register field is ignored, and the E xtendedRegister field is used for the register number.

Status Codes Returned

EFI_SUCCESS	The data was read from or written to the PCI root bridge.
EFI_INVALID_PARAMETER	Width is invalid for this PCI root bridge.
EFI_INVALID_PARAMETER	Buffer is *NULL*.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.

14.2.10 EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.CopyMem()

Summary

Enables a PCI driver to copy one region of PCI root bridge memory space to another region of PCI root bridge memory space.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_COPY_MEM) (
  IN EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL             *This,
  IN EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_WIDTH       Width,
  IN UINT64                                      DestAddress,
  IN UINT64                                      SrcAddress,
  IN UINTN                                       Count
  );
```

Parameters

This

A pointer to the *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL*. Type EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL is defined in *PCI Root Bridge I/O Protocol* .

Width

Signifies the width of the memory operation. Type EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_WIDTH see **Related Definitions** in the section *PCI Root Bridge I/O Protocol* .

DestAddress

The destination address of the memory operation. The caller is responsible for aligning the DestAddress if required.

SrcAddress

The source address of the memory operation. The caller is responsible for aligning the SrcAddress if required.

Count

The number of memory operations to perform. Bytes moved is Width size * Count, starting at DestAddress and SrcAddress.

Description

The *CopyMem()* function enables a PCI driver to copy one region of PCI root bridge memory space to another region of PCI root bridge memory space. This is especially useful for video scroll operation on a memory mapped video buffer.

The memory operations are carried out exactly as requested. The caller is responsible for satisfying any alignment and memory width restrictions that a PCI root bridge on a platform might require. For example on some platforms, width requests of *EfiPciWidthUint64* do not work.

If *Width* is *EfiPciIoWidthUint8* , *EfiPciIoWidthUint16* , *EfiPciIoWidthUint32* , or *EfiPciIoWidthUint64* , then *Count* read/write transactions are performed to move the contents of the *SrcAddress* buffer to the *DestAddress* buffer. The implementation must be reentrant, and it must handle overlapping *SrcAddress* and *DestAddress* buffers. This means that the implementation of *CopyMem()* must choose the correct direction of the copy operation based on the type of overlap that exists between the *SrcAddress* and *DestAddress* buffers. If either the *SrcAddress* buffer or the *DestAddress* buffer crosses the top of the processor's address space, then the result of the copy operation is unpredictable.

The contents of the *DestAddress* buffer on exit from this service must match the contents of the *SrcAddress* buffer on entry to this service. Due to potential overlaps, the contents of the *SrcAddress* buffer may be modified by this service. The following rules can be used to guarantee the correct behavior:

- If *DestAddress* > *SrcAddress* and *DestAddress* < (*SrcAddress* + *Width* size * *Count*), then the data should be copied from the *SrcAddress* buffer to the *DestAddress* buffer starting from the end of buffers and working toward the beginning of the buffers.
- Otherwise, the data should be copied from the *SrcAddress* buffer to the *DestAddress* buffer starting from the beginning of the buffers and working toward the end of the buffers.

All the PCI transactions generated by this function are guaranteed to be completed before this function returns. All the PCI write transactions generated by this function will follow the write ordering and completion rules defined in the PCI Specification. However, if the memory-mapped I/O region being accessed by this function has the *EFI_PCI_ATTRIBUTE_MEMORY_CACHED* attribute set, then the transactions will follow the ordering rules defined by the processor architecture.

Status Codes Returned

EFI_SUCCESS	The data was copied from one memory region to another memory region.
EFI_INVALID_PARAMETER	Width is invalid for this PCI root bridge.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.

14.2.11 EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.Map()

Summary

Provides the PCI controller-specific addresses required to access system memory from a DMA bus master.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_MAP) (
  IN EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL                *This,
  IN EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_OPERATION      Operation,
  IN VOID                                           *HostAddress,
  IN OUT UINTN                                      *NumberOfBytes,
  OUT EFI_PHYSICAL_ADDRESS                          *DeviceAddress,
  OUT VOID                                          **Mapping
  );
```

Parameters

This

A pointer to the *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL*. Type EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL is defined in *PCI Root Bridge I/O Protocol* .

Operation

Indicates if the bus master is going to read or write to system memory. Type EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_OPERATION defined in Section *PCI Root Bridge I/O Protocol* .

HostAddress

The system memory address to map to the PCI controller.

NumberOfBytes

On input the number of bytes to map. On output the number of bytes that were mapped.

DeviceAddress

The resulting map address for the bus master PCI controller to use to access the system memory's *HostAddress*. Type EFI_PHYSICAL_ADDRESS , defined in *EFI_BOOT_SERVICES.AllocatePool()*. This address cannot be used by the processor to access the contents of the buffer specified by *HostAddress*.

Mapping

The value to pass to *Unmap()* when the bus master DMA operation is complete.

Description

The *Map()* function provides the PCI controller specific addresses needed to access system memory. This function is used to map system memory for PCI bus master DMA accesses.

All PCI bus master accesses must be performed through their mapped addresses and such mappings must be freed with *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.Unmap()* when complete. If the bus master access is a single read or single write data transfer, then *EfiPciOperationBusMasterRead* , *EfiPciOperationBusMasterRead64* , *EfiPciOperationBusMasterWrite* , or *EfiPciOperationBusMasterWrite64* is used and the range is unmapped to complete the operation. If performing an *EfiPciOperationBusMasterRead* or *EfiPciOperationBusMasterRead64* operation, all the data must be present in system memory before *Map()* is performed. Similarly, if performing an *EfiPciOperationBusMasterWrite* or *EfiPciOperationBusMasterWrite64* the data cannot be properly accessed in system memory until *Unmap()* is performed.

Bus master operations that require both read and write access or require multiple host device interactions within the same mapped region must use *EfiPciOperation-BusMasterCommonBuffer* or *EfiPciOperationBusMasterCommonBuffer64*. However, only memory allocated via the *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.AllocateBuffer()* interface can be mapped for this type of operation.

In all mapping requests the resulting *NumberOfBytes* actually mapped may be less than the requested amount. In this case, the DMA operation will have to be broken up into smaller chunks. The *Map()* function will map as much of the DMA operation as it can at one time. The caller may have to loop on *Map()* and *Unmap()* in order to complete a large DMA transfer.

Status Codes Returned

EFI_SUCCESS	The range was mapped for the returned NumberOfBytes.
EFI_INVALID_PARAMETER	Operation is invalid.
EFI_INVALID_PARAMETER	*HostAddress* is *NULL*.
EFI_INVALID_PARAMETER	*NumberOfBytes* is *NULL*.
EFI_INVALID_PARAMETER	*DeviceAddress* is *NULL*.
EFI_INVALID_PARAMETER	*Mapping* is *NULL*.
EFI_UNSUPPORTED	The HostAddress cannot be mapped as a common buffer.
EFI_DEVICE_ERROR	The system hardware could not map the requested address.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.

14.2.12 EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.Unmap()

Summary

Completes the *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.Map()* operation and releases any corresponding resources.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_UNMAP) (
  IN EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL              *This,
  IN VOID                                         *Mapping
  );
```

Parameters

This

A pointer to the *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL*. Type EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL , defined in *PCI Root Bridge I/O Protocol* .

Mapping

The mapping value returned from Map().

Description

The *Unmap()* function completes the *Map()* operation and releases any corresponding resources. If the operation was an *EfiPciOperationBusMasterWrite* or *EfiPciOperationBusMasterWrite64* , the data is committed to the target system memory. Any resources used for the mapping are freed.

Status Codes Returned

EFI_SUCCESS	The range was unmapped.
EFI_INVALID_PARAMETER	Mapping is not a value that was returned by *Map()*.
EFI_DEVICE_ERROR	The data was not committed to the target system memory.

14.2.13 EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.AllocateBuffer()

Summary

Allocates pages that are suitable for an *EfiPciOperationBusMasterCommonBuffer* or *EfiPciOperationBusMasterCommonBuffer64* mapping.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_ALLOCATE_BUFFER) (
  IN EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL              *This,
  IN EFI_ALLOCATE_TYPE                            Type,
  IN EFI_MEMORY_TYPE                              MemoryType,
  IN UINTN                                        Pages,
  OUT VOID                                        **HostAddress,
  IN UINT64                                       Attributes
  );
```

Parameters

This

A pointer to the *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL* . Type EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL is defined in Section *PCI Root Bridge I/O Protocol* .

Type

This parameter is not used and must be ignored.

Memory

Type The type of memory to allocate, *EfiBootServicesData* or *EfiRuntimeServicesData*. Type EFI_MEMORY_TYPE is defined in *EFI_BOOT_SERVICES.AllocatePages()*.

Pages

The number of pages to allocate.

HostAddress

A pointer to store the base system memory address of the allocated range.

Attributes

The requested bit mask of attributes for the allocated range. Only the attributes *EFI_PCI_ATTRIBUTE_MEMORY_WRITE_COMBINE* , *EFI_PCI_ATTRIBUTE_MEMORY_CACHED* , and *EFI_PCI_ATTRIBUTE_DUAL_ADDRESS_CYCLE* may be used with this function. If any other bits are set, then *EFI_UNSUPPORTED* is returned. This function may choose to ignore this bit mask. The *EFI_PCI_ATTRIBUTE_MEMORY_WRITE_COMBINE* , and *EFI_PCI_ATTRIBUTE_MEMORY_CACHED* attributes provide a hint to the implementation that may improve the performance of the calling driver. The implementation may choose any default for the memory attributes including write combining, cached, both, or neither as long as the allocated buffer can be seen equally by both the processor and the PCI bus master.

Description

The *AllocateBuffer()* function allocates pages that are suitable for an *EfiPciOperationBusMasterCommonBuffer* or *EfiPciOperationBusMasterCommonBuffer64* mapping. This means that the buffer allocated by this function must support simultaneous access by both the processor and a PCI Bus Master. The device address that the PCI Bus Master uses to access the buffer can be retrieved with a call to *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.Map()* .

If the *EFI_PCI_ATTRIBUTE_DUAL_ADDRESS_CYCLE* bit of *Attributes* is set, then when the buffer allocated by this function is mapped with a call to *Map()* , the device address that is returned by *Map()* must be within the 64-bit device address space of the PCI Bus Master.

If the *EFI_PCI_ATTRIBUTE_DUAL_ADDRESS_CYCLE* bit of *Attributes* is clear, then when the buffer allocated by this function is mapped with a call to *Map()* , the device address that is returned by *Map()* must be within the 32-bit device address space of the PCI Bus Master.

If the memory allocation specified by *MemoryType* and *Pages* cannot be satisfied, then *EFI_OUT_OF_RESOURCES* is returned.

Status Codes Returned

EFI_SUCCESS	The requested memory pages were allocated.
EFI_INVALID_PARAMETER	MemoryType is invalid.
EFI_INVALID_PARAMETER	*HostAddress* is *NULL*.
EFI_UNSUPPORTED	*Attributes* is unsupported. The only legal attribute bits are *EFI_PCI_ATTRIBUTE_MEMORY_WRITE_COMBINE* , *EFI_PCI_ATTRIBUTE_MEMORY_CACHED* , and *EFI_PCI_ATTRIBUTE_DUAL_ADDRESS_CYCLE*.

continues on next page

Table 14.10 – continued from previous page

EFI_OUT_OF_RESOURCES	The memory pages could not be allocated.

14.2.14 EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.FreeBuffer()

Summary

Frees memory that was allocated with *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.AllocateBuffer()*.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_FREE_BUFFER) (
  IN EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL                  *This,
  IN UINTN                                            Pages,
  IN VOID                                             *HostAddress
  );
```

Parameters

This

A pointer to the *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL*. Type EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL is defined in *PCI Root Bridge I/O Protocol* .

Pages

The number of pages to free.

HostAddress

The base system memory address of the allocated range.

Description

The *FreeBuffer()* function frees memory that was allocated with *AllocateBuffer()*.

Status Codes Returned

EFI_SUCCESS	The requested memory pages were freed.
EFI_INVALID_PARAMETER	The memory range specified by HostAddress and Pages was not allocated with *AllocateBuffer()*.

14.2.15 EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.Flush()

Summary

Flushes all PCI posted write transactions from a PCI host bridge to system memory.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_FLUSH) (
  IN EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL                    *This
  );
```

Parameters

This

A pointer to the *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL*. Type EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL is defined in Section *PCI Root Bridge I/O Protocol* .

Description

The *Flush()* function flushes any PCI posted write transactions from a PCI host bridge to system memory. Posted write transactions are generated by PCI bus masters when they perform write transactions to target addresses in system memory.

This function does not flush posted write transactions from any PCI bridges. A PCI controller specific action must be taken to guarantee that the posted write transactions have been flushed from the PCI controller and from all the PCI bridges into the PCI host bridge. This is typically done with a PCI read transaction from the PCI controller prior to calling *Flush()*.

If the PCI controller specific action required to flush the PCI posted write transactions has been performed, and this function returns *EFI_SUCCESS* , then the PCI bus master's view and the processor's view of system memory are guaranteed to be coherent. If the PCI posted write transactions cannot be flushed from the PCI host bridge, then the PCI bus master and processor are not guaranteed to have a coherent view of system memory, and *EFI_DEVICE_ERROR* is returned.

Status Codes Returned

EFI_SUCCESS	The PCI posted write transactions were flushed from the PCI host bridge to system memory.
EFI_DEVICE_ERROR	The PCI posted write transactions were not flushed from the PCI host bridge due to a hardware error.

14.2.16 EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.GetAttributes()

Summary

Gets the attributes that a PCI root bridge supports setting with *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.SetAttributes()* , and the attributes that a PCI root bridge is currently using. **Prototype**

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_GET_ATTRIBUTES) (
  IN EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL             *This,
  OUT UINT64                                     *Supports OPTIONAL,
  OUT UINT64                                     *Attributes OPTIONAL
  );
```

Parameters

This

A pointer to the *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL*. Type EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL is defined in Section *PCI Root Bridge I/O Protocol* .

Supports

A pointer to the mask of attributes that this PCI root bridge supports setting with SetAttributes(). The available attributes are listed in See *PCI Root Bridge I/O Protocol*. This is an optional parameter that may be **NULL**.

Attributes

A pointer to the mask of attributes that this PCI root bridge is currently using. The available attributes are listed in See *PCI Root Bridge I/O Protocol*. This is an optional parameter that may be **NULL**.

Description

The *GetAttributes()* function returns the mask of attributes that this PCI root bridge supports and the mask of attributes that the PCI root bridge is currently using. If *Supports* is not *NULL* , then *Supports* is set to the mask of attributes that the PCI root bridge supports. If *Attributes* is not *NULL* , then *Attributes* is set to the mask of attributes that the PCI root bridge is currently using. If both *Supports* and *Attributes* are *NULL* , then *EFI_INVALID_PARAMETER* is returned. Otherwise, *EFI_SUCCESS* is returned.

If a bit is set in *Supports* , then the PCI root bridge supports this attribute type, and a call can be made to *SetAttributes()* using that attribute type. If a bit is set in *Attributes* , then the PCI root bridge is currently using that attribute type. Since a PCI host bus may be composed of more than one PCI root bridge, different *Attributes* values may be returned by different PCI root bridges.

Status Codes Returned

EFI_SUCCESS	If Supports is not *NULL* , then the attributes that the PCI root bridge supports is returned in Supports. If Attributes is not *NULL* , then the attributes that the PCI root bridge is currently using is returned in Attributes.
EFI_INVALID_PARAMETER	Both Supports and Attributes are *NULL*.

14.2.17 EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.SetAttributes()

Summary

Sets attributes for a resource range on a PCI root bridge.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_SET_ATTRIBUTES) (
  IN EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL        *This,
  IN UINT64                                 Attributes,
  IN OUT UINT64                             *ResourceBase OPTIONAL,
  IN OUT UINT64                             *ResourceLength OPTIONAL
  );
```

Parameters

This

A pointer to the See *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL*. Type EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL is defined in See *PCI Root Bridge I/O Protocol*.

Attributes

The mask of attributes to set. If the attribute bit MEMORY_WRITE_COMBINE, MEMORY_CACHED, or MEMORY_DISABLE is set, then the resource range is specified by ResourceBase and ResourceLength. If MEMORY_WRITE_COMBINE, MEMORY_CACHED, and MEMORY_DISABLE are not set, then ResourceBase and ResourceLength are ignored, and may be NULL. The available attributes are listed in See *PCI Root Bridge I/O Protocol*.

ResourceBase

A pointer to the base address of the resource range to be modified by the attributes specified by Attributes. On return, *ResourceBase* will be set the actual base address of the resource range. Not all resources can be set to a byte boundary, so the actual base address may differ from the one passed in by the caller. This parameter is only used if the MEMORY_WRITE_COMBINE bit, the MEMORY_CACHED bit, or the MEMORY_DISABLE bit of Attributes is set. Otherwise, it is ignored, and may be **NULL**.

ResourceLength

A pointer to the length of the resource range to be modified by the attributes specified by Attributes. On return, *ResourceLength will be set the actual length of the resource range. Not all resources can be set to a byte boundary, so the actual length may differ from the one passed in by the caller. This parameter is only used if the MEMORY_WRITE_COMBINE bit, the MEMORY_CACHED bit, or the MEMORY_DISABLE bit of Attributes is set. Otherwise, it is ignored, and may be **NULL*.*

Description

The *SetAttributes()* function sets the attributes specified in *Attributes* for the PCI root bridge on the resource range specified by *ResourceBase* and *ResourceLength*. Since the granularity of setting these attributes may vary from resource type to resource type, and from platform to platform, the actual resource range and the one passed in by the caller may differ. As a result, this function may set the attributes specified by *Attributes* on a larger resource range than the caller requested. The actual range is returned in *ResourceBase* and *ResourceLength*. The caller is responsible for verifying that the actual range for which the attributes were set is acceptable.

If the attributes are set on the PCI root bridge, then the actual resource range is returned in *ResourceBase* and *ResourceLength* , and *EFI_SUCCESS* is returned.

If the attributes specified by *Attributes* are not supported by the PCI root bridge, then *EFI_UNSUPPORTED* is returned. The set of supported attributes for a PCI root bridge can be found by calling *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.GetAttributes()*.

If either *ResourceBase* or *ResourceLength* are *NULL* , and a resource range is required for the attributes specified in *Attributes* , then *EFI_INVALID_PARAMETER* is returned.

If more than one resource range is required for the set of attributes specified by *Attributes* , then *EFI_INVALID_PARAMETER* is returned.

If there are not enough resources available to set the attributes, then *EFI_OUT_OF_RESOURCES* is returned.

Status Codes Returned

EFI_SUCCESS	The set of attributes specified by Attributes for the resource range specified by ResourceBase and ResourceLength were set on the PCI root bridge, and the actual resource range is returned in ResuourceBase and ResourceLength.
EFI_UNSUPPORTED	A bit is set in Attributes that is not supported by the PCI Root Bridge. The supported attribute bits are reported by *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.GetAttributes()*
EFI_INVALID_PARAMETER	More than one attribute bit is set in Attributes that requires a resource range.
EFI_INVALID_PARAMETER	A resource range is required, and ResourceBase is *NULL*.
EFI_INVALID_PARAMETER	A resource range is required, and ResourceLength is *NULL*.
EFI_OUT_OF_RESOURCES	There are not enough resources to set the attributes on the resource range specified by BaseAddress and Length.

14.2.18 EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.Configuration()

Summary

Retrieves the current resource settings of this PCI root bridge in the form of a set of ACPI resource descriptors.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL_CONFIGURATION) (
  IN EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL          *This,
```

(continues on next page)

(continued from previous page)

```
OUT VOID                                              **Resources
);
```

Parameters

This

A pointer to the EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL, which is defined in *PCI Root Bridge I/O Protocol*.

Resources

A pointer to the resource descriptors that describe the current configuration of this PCI root bridge. The storage for the resource descriptors is allocated by this function. The caller must treat the return buffer as read-only data, and the buffer must not be freed by the caller. See “Related Definitions” for the resource descriptors that may be used.

Related Definitions

There are only two resource descriptor types from the ACPI Specification that may be used to describe the current resources allocated to a PCI root bridge. These are the QWORD Address Space Descriptor, and the End Tag. The QWORD Address Space Descriptor can describe memory, I/O, and bus number ranges for dynamic or fixed resources. The configuration of a PCI root bridge is described in the Tables below with one or more QWORD Address Space Descriptors followed by an End Tag which contain these two descriptor types.

Please see the ACPI Specification for details on the field values. The definition of the Address Space Granularity field in the QWORD Address Space Descriptor differs from the ACPI Specification, and the definition in the table below is the one that must be used.

Table 14.15: QWORD Address Space Descriptor

Byte Offset	Byte Length	Data	Description
0x00	0x01	0x8A	QWORD Address Space Descriptor
0x01	0x02	0x2B	Length of this descriptor in bytes not including the first two fields
0x03	0x01		Resource Type 0 - Memory Range 1 - I/O Range 2 - Bus Number Range
0x04	0x01		General Flags
0x05	0x01		Type Specific Flags
0x06	0x08		Address Space Granularity. Used to differentiate between a 32-bit memory request and a 64-bit memory request. For a 32-bit memory request, this field should be set to 32. For a 64-bit memory request, this field should be set to 64.
0x0E	0x08		Address Range Minimum
0x16	0x08		Address Range Maximum
0x1E	0x08		Address Translation Offset. Offset to apply to the Starting address to convert it to a PCI address. This value is zero unless the HostAddress and DeviceAddress for the root bridge are different.
0x26	0x08		Address Length

Table 14.16: End Tag

Byte Offset	Byte Length	Data	Description
0x00	0x01	0x79	End Tag
0x01	0x01	0x00	Checksum. If 0, then checksum is assumed to be valid.

Description

The *Configuration()* function retrieves a set of resource descriptors that contains the current configuration of this PCI root bridge. If the current configuration can be retrieved, then it is returned in *Resources* and *EFI_SUCCESS* is returned. See "Related Definitions" below for the resource descriptor types that are supported by this function. If the current configuration cannot be retrieved, then *EFI_UNSUPPORTED* is returned.

Status Codes Returned

EFI_SUCCESS	The current configuration of this PCI root bridge was returned in Resources.
EFI_UNSUPPORTED	The current configuration of this PCI root bridge could not be retrieved.

14.2.19 PCI Root Bridge Device Paths

See *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL* must be installed on a handle for its services to be available to drivers. In addition to the *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL* , an *EFI Device Path Protocol* must also be installed on the same handle.

Typically, an ACPI Device Path Node is used to describe a PCI Root Bridge. Depending on the bus hierarchy in the system, additional device path nodes may precede this ACPI Device Path Node. A desktop system will typically contain only one PCI Root Bridge, so there would be one handle with a *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL* and an *EFI_DEVICE_PATH_PROTOCOL* A server system may contain multiple PCI Root Bridges, so it would contain a handle for each PCI Root Bridge present, and on each of those handles would be an *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL* and an *EFI_DEVICE_PATH_PROTOCOL*. In all cases, the contents of the ACPI Device Path Nodes for PCI Root Bridges must match the information present in the ACPI tables for that system.

Table below: *PCI Root Bridge Device Path for a Desktop System* shows an example device path for a PCI Root Bridge in a desktop system. Today, a desktop system typically contains one PCI Root Bridge. This device path consists of an ACPI Device Path Node, and a Device Path End Structure. The _HID and _UID must match the ACPI table description of the PCI Root Bridge. For a system with only one PCI Root Bridge, the _UID value is usually 0x0000. The shorthand notation for this device path is *ACPI(PNP0A03,0)*.

Table 14.18: PCI Root Bridge Device Path for a Desktop System

Byte Offset	**Byte Length**	**Data**	**Description**
0x00	0x01	0x02	Generic Device Path Header - Type ACPI Device Path
0x01	0x01	0x01	Sub type - ACPI Device Path
0x02	0x02	0x0C	Length - 0x0C bytes
0x04	0x04	0x41D0, 0x0A03	_HID PNP0A03 - 0x41D0 represents the compressed string 'PNP' and is encoded in the low order bytes. The compression method is described in the ACPI Specification.
0x08	0x04	0x0000	_UID
0x0C	0x01	0x7F	Generic Device Path Header - Type End of Hardware Device Path
0x0D	0x01	0xFF	Sub type - End of Entire Device Path
0x0E	0x02	0x04	Length - 0x04 bytes

In the Tables belows, *PCI Root Bridge Device Path for Bridge #0 in a Server System* through *PCI Root Bridge Device Path for Bridge #3 in a Server System* show example device paths for the PCI Root Bridges in a server system with four PCI Root Bridges. Each of these device paths consists of an ACPI Device Path Node, and a Device Path End Structure. The _HID and _UID must match the ACPI table description of the PCI Root Bridges. The only difference between each of these device paths is the _UID field. The shorthand notation for these four device paths is *ACPI(PNP0A03,0)* , *ACPI(PNP0A03,1)* , *ACPI(PNP0A03,2)* , and *ACPI(PNP0A03,3)*.

Table 14.19: PCI Root Bridge Device Path for Bridge #0 in a Server System

Byte Offset	Byte Length	Data	Description
0x00	0x01	0x02	Generic Device Path Header - Type ACPI Device Path
0x01	0x01	0x01	Sub type - ACPI Device Path
0x02	0x02	0x0C	Length - 0x0C bytes
0x04	0x04	0x41D0, 0x0A03	_HID PNP0A03 - 0x41D0 represents the compressed string ‘PNP’ and is encoded in the low order bytes. The compression method is described in the ACPI Specification.
0x08	0x04	0x0000	_UID
0x0C	0x01	0x7F	Generic Device Path Header - Type End of Hardware Device Path
0x0D	0x01	0xFF	Sub type - End of Entire Device Path
0x0E	0x02	0x04	Length - 0x04 bytes

Table 14.20: PCI Root Bridge Device Path for Bridge #1 in aServer System

Byte Offset	Byte Length	Data	Description
0x00	0x01	0x02	Generic Device Path Header - Type ACPI Device Path
0x01	0x01	0x01	Sub type - ACPI Device Path
0x02	0x02	0x0C	Length - 0x0C bytes
0x04	0x04	0x41D0, 0x0A03	_HID PNP0A03 - 0x41D0 represents the compressed string ‘PNP’ and is encoded in the low order bytes. The compression method is described in the ACPI Specification.
0x08	0x04	0x0001	_UID
0x0C	0x01	0x7F	Generic Device Path Header - Type End of Hardware Device Path
0x0D	0x01	0xFF	Sub type - End of Entire Device Path
0x0E	0x02	0x04	Length - 0x04 bytes

0x11	0x01	0xFF	Sub type - End of Entire Device Path
0x12	0x02	0x04	Length - 0x04 bytes

14.3 PCI Driver Model

PCI Driver Model and *EFI PCI I/O Protocol* describe the PCI Driver Model. This includes the behavior of PCI Bus Drivers, the behavior of a PCI Device Drivers, and a detailed description of the PCI I/O Protocol. The PCI Bus Driver manages PCI buses present in a system, and PCI Device Drivers manage PCI controllers present on PCI buses. The PCI Device Drivers produce an I/O abstraction that can be used to boot an EFI compliant operating system.

This document provides enough material to implement a PCI Bus Driver, and the tools required to design and implement a PCI Device Drivers. It does not provide any information on specific PCI devices.

The material contained in this section is designed to extend this specification and the UEFI Driver Model in a way that supports PCI device drivers and PCI bus drivers. These extensions are provided in the form of PCI-specific protocols. This section provides the information required to implement a PCI Bus Driver in system firmware. The section also contains the information required by driver writers to design and implement PCI Device Drivers that a platform may need to boot a UEFI-compliant OS.

The PCI Driver Model described here is intended to be a foundation on which a PCI Bus Driver and a wide variety of PCI Device Drivers can be created.

14.3.1 PCI Driver Initialization

There are very few differences between a PCI Bus Driver and PCI Device Driver in the entry point of the driver. The file for a driver image must be loaded from some type of media. This could include ROM, FLASH, hard drives, floppy drives, CD-ROM, or even a network connection. Once a driver image has been found, it can be loaded into system memory with the Boot Service: *EFI_BOOT_SERVICES.LoadImage()*. *LoadImage()* loads a PE/COFF formatted image into system memory. A handle is created for the driver, and a Loaded Image Protocol instance is placed on that handle. A handle that contains a Loaded Image Protocol instance is called an Image Handle. At this point, the driver has not been started. It is just sitting in memory waiting to be started. The figure below shows the state of an image handle for a driver after *LoadImage()* has been called.

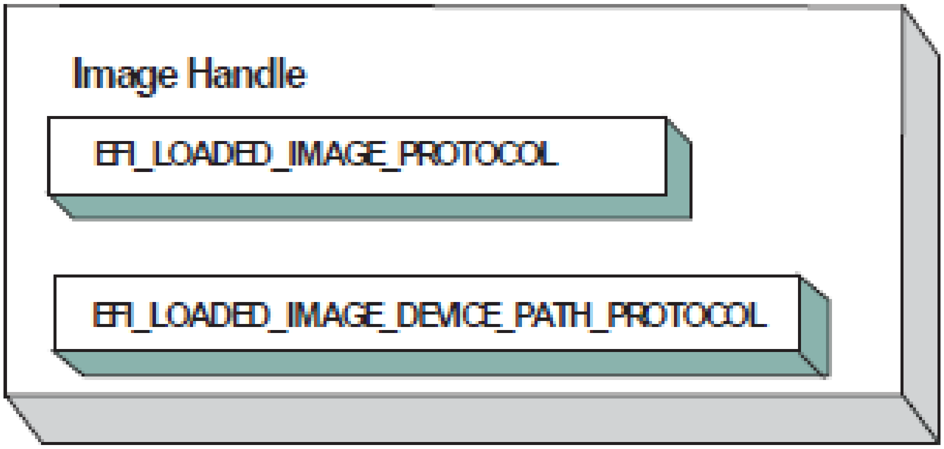

Fig. 14.7: **Image Handle**

After a driver has been loaded with the Boot Service *EFI_BOOT_SERVICES.LoadImage()*, it must be started with the Boot Service *EFI_BOOT_SERVICES.StartImage()*. This is true of all types of applications and drivers that can be loaded and started on an UEFI compliant system. The entry point for a driver that follows the UEFI Driver Model must follow some strict rules. First, it is not allowed to touch any hardware. Instead, it is only allowed to install protocol instances onto its own Image Handle. A driver that follows the UEFI Driver Model is required to install an instance of the Driver Binding Protocol onto its own Image Handle. It may optionally install the Driver Diagnostics

Protocol or the Component Name Protocol. In addition, if a driver wishes to be unloadable it may optionally update the Loaded Image Protocol to provide its own Unload() *EFI_LOADED_IMAGE_PROTOCOL.Unload()* function. Finally, if a driver needs to perform any special operations when the Boot Service EFI_BOOT_SERVICES is called (*Services — Boot Services*), the driver may optionally create an event with a notification function that is triggered when the Boot Service *ExitBootServices()* is called. An Image Handle that contains a Driver Binding Protocol instance is known as a Driver Image Handle. The Figure below, *PCI Driver Image Handle*, shows a possible configuration for the Image Handle from figure: *Image Handle* after the Boot Service *StartImage()* has been called.

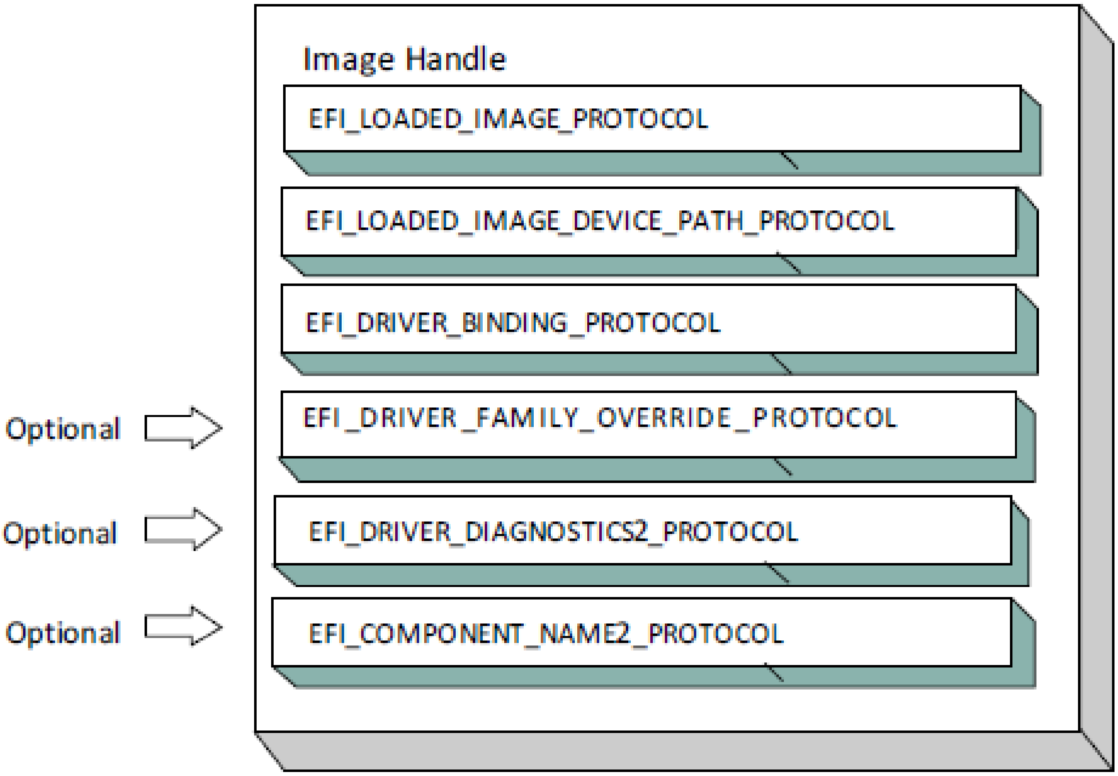

Fig. 14.8: **PCI Driver Image Handle**

14.3.2 Driver Diagnostics Protocol

If a PCI Bus Driver or a PCI Device Driver requires diagnostics, then an *EFI_DRIVER_DIAGNOSTICS2_PROTOCOL* must be installed on the image handle in the entry point for the driver. This protocol contains functions to perform diagnostics on a controller. The *EFI_DRIVER_DIAGNOSTICS2_PROTOCOL* is not allowed to interact with the user. Instead, it must return status information through a bffer. The functions of this protocol will be invoked by a platform management utility.

14.3.3 Component Name Protocol

Both a PCI Bus Driver and a PCI Device Driver are able to produce user readable names for the PCI drivers and/or the set of PCI controllers that the PCI drivers are managing. This is accomplished by installing an instance of the *EFI_COMPONENT_NAME2_PROTOCOL* on the image handle of the driver. This protocol can produce driver and controller names in the form of a string in one of several languages. This protocol can be used by a platform management utility to display user readable names for the drivers and controllers present in a system. Please see the EFI Driver Model Specification for details on the *EFI_COMPONENT_NAME2_PROTOCOL*.

14.3.4 Driver Family Override Protocol

If a PCI Bus Driver or PCI Device Driver always wants the PCI driver delivered in a PCI Option ROM to manage the PCI controller associated with the PCI Option ROM, then the Driver Family Override Protocol must not be produced.

If a PCI Bus Driver or PCI Device Driver always wants the PCI driver with the highest Version value in the Driver Binding Protocol to manage all the PCI Controllers in the same family of PCI controllers, then the Driver Family Override Protocol must be produced on the same handle as the Driver Binding Protocol.

14.3.5 PCI Bus Drivers

A PCI Bus Driver manages PCI Host Bus Controllers that can contain one or more PCI Root Bridges. *PCI Host Bus Controller* shows an example of a desktop system that has one PCI Host Bus Controller with one PCI Root Bridge.

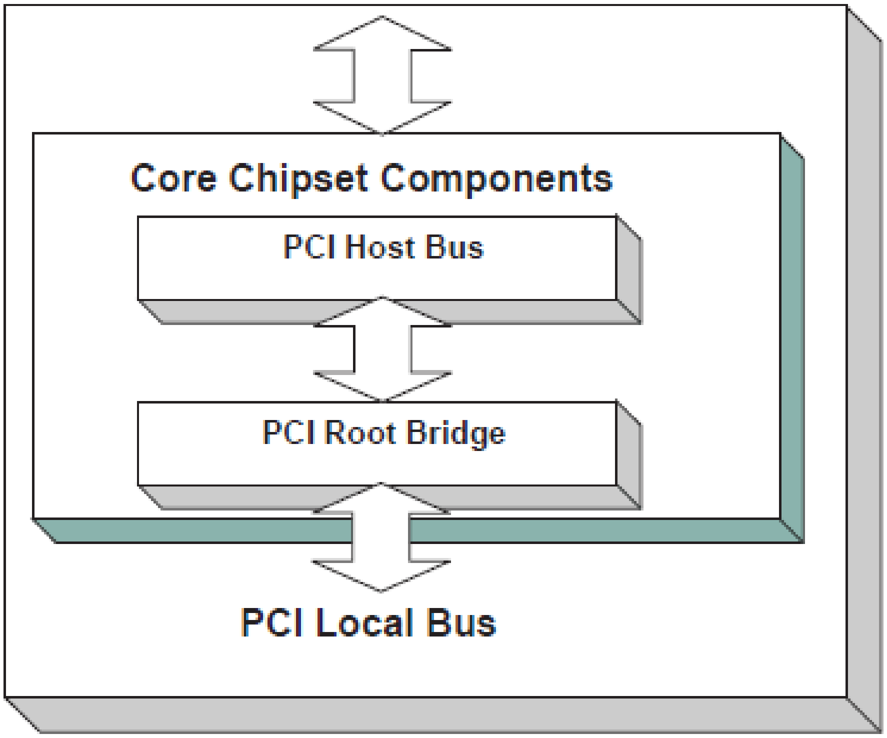

Fig. 14.9: PCI Host Bus Controller

The PCI Host Bus Controller shown above is abstracted in software with the PCI Root Bridge I/O Protocol. A PCI Bus Driver will manage handles that contain this protocol. *Device Handle for a PCI Host Bus Controller* shows an example device handle for a PCI Host Bus Controller. It contains a Device Path Protocol instance and a PCI Root Bridge I/O Protocol Instance.

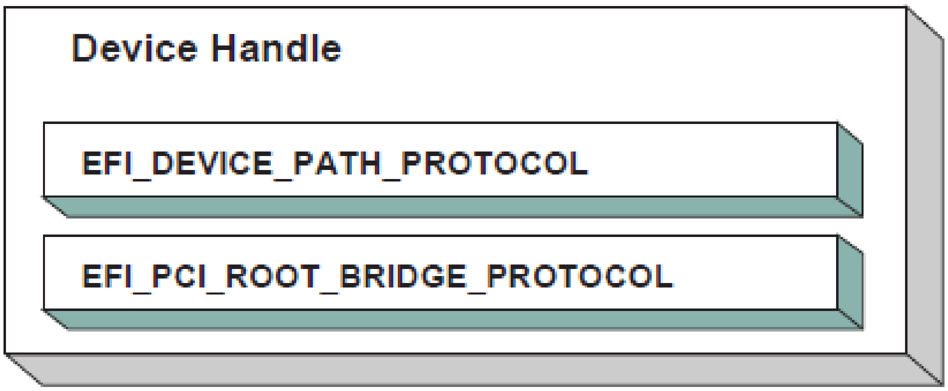

Fig. 14.10: Device Handle for a PCI Host Bus Controller

14.3.6 Driver Binding Protocol for PCI Bus Drivers

The Driver Binding Protocol contains three services. These are Supported() *EFI_DRIVER_BINDING_PROTOCOL.Supported()* , *EFI_DRIVER_BINDING_PROTOCOL.Start()*, and *EFI_DRIVER_BINDING_PROTOCOL.Stop()*. *Supported()* tests to see if the PCI Bus Driver can manage a device handle. A PCI Bus Driver can only manage device handles that contain the Device Path Protocol and the PCI Root Bridge I/O Protocol, so a PCI Bus Driver must look for these two protocols on the device handle that is being tested.

The *Start()* function tells the PCI Bus Driver to start managing a device handle. The device handle should support the protocols shown in *Device Handle for a PCI Host Bus Controller*. The PCI Root Bridge I/O Protocols provides access to the PCI I/O, PCI Memory, PCI Prefetchable Memory, and PCI DMA functions. The PCI Controllers behind a PCI Root Bridge may exist on one or more PCI Buses. The standard mechanism for expanding the number of PCI Buses on a single PCI Root Bridge is to use PCI to PCI Bridges. Once a PCI Enumerator configures these bridges, they are invisible to software. As a result, the PCI Bus Driver flattens the PCI Bus hierarchy when it starts managing a device handle that represents a PCI Host Controller. *Physical PCI Bus Structure* shows the physical tree structure for a set of PCI Device denoted by A, B, C, D, and E. Device A and C are PCI to PCI Bridges.

Connecting a PCI Bus Driver shows the tree structure generated by a PCI Bus Driver before and after *Start()* is called. This is a logical view of set of PCI controller, and not a physical view. The physical tree is flattened, so any PCI to PCI bridge devices are invisible. In this example, the PCI Bus Driver finds the five child PCI Controllers on the PCI Bus from *Physical PCI Bus Structure*. A device handle is created for every PCI Controller including all the PCI to PCI Bridges. The arrow with the dashed line coming into the PCI Host Bus Controller represents a link to the PCI Host Bus Controller's parent. If the PCI Host Bus Controller is a Root Bus Controller, then it will not have a parent. The PCI Driver Model does not require that a PCI Host Bus Controller be a Root Bus Controller. A PCI Host Bus Controller can be present at any location in the tree, and the PCI Bus Driver should be able to manage the PCI Host Bus Controller.

The PCI Bus Driver has the option of creating all of its children in one call to *EFI_DRIVER_BINDING_PROTOCOL.Start()* , or spreading it across several calls to *Start()*. In general, if it is possible to design a bus driver to create one child at a time, it should do so to support the rapid boot capability in the UEFI Driver Model. Each of the child device handles created in *Start()* must contain a Device Path Protocol instance, a PCI I/O protocol instance, and optionally a Bus Specific Driver Override Protocol instance. The PCI I/O Protocol is described in *EFI PCI I/O Protocol*. The format of device paths for PCI Controllers is described in Section 2.6, and details on the Bus Specific Driver Override Protocol can be found in the EFI Driver Model Specification. The Figure below shows an example child device handle that is created by a PCI Bus Driver for a PCI Controller.

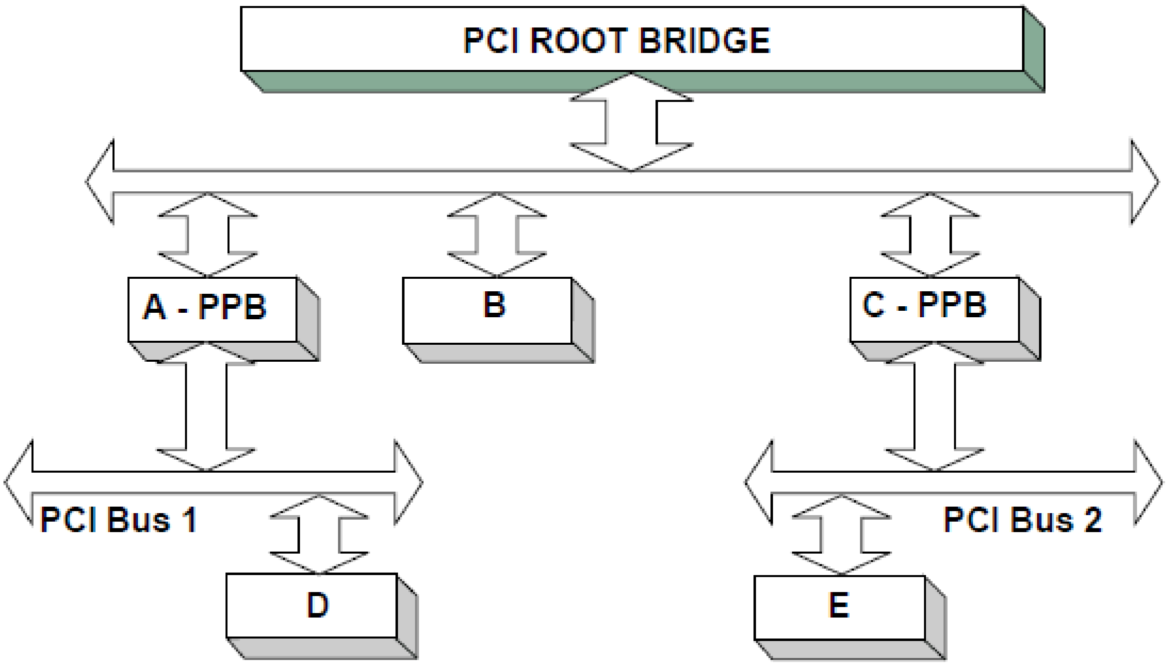

Fig. 14.11: Physical PCI Bus Structure

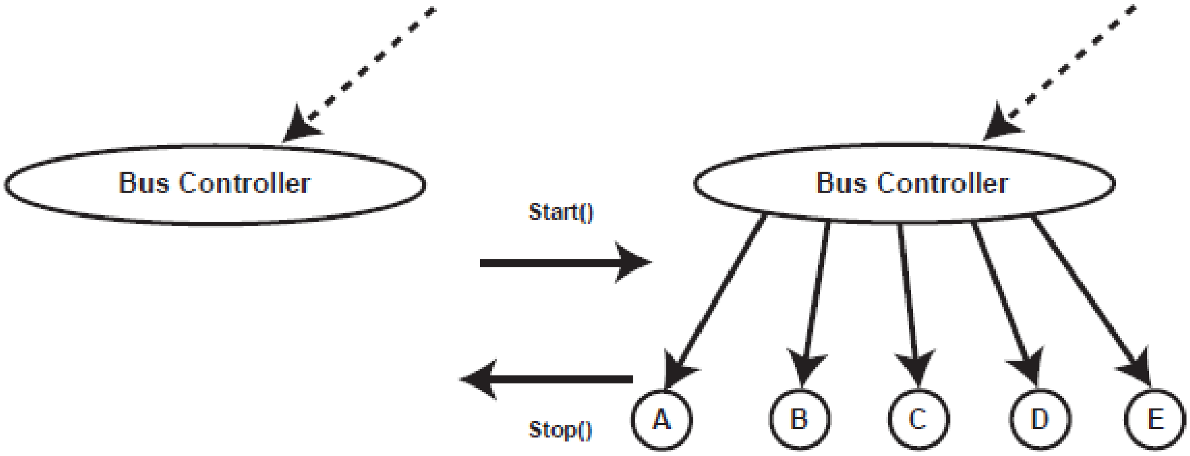

Fig. 14.12: Connecting a PCI Bus Driver

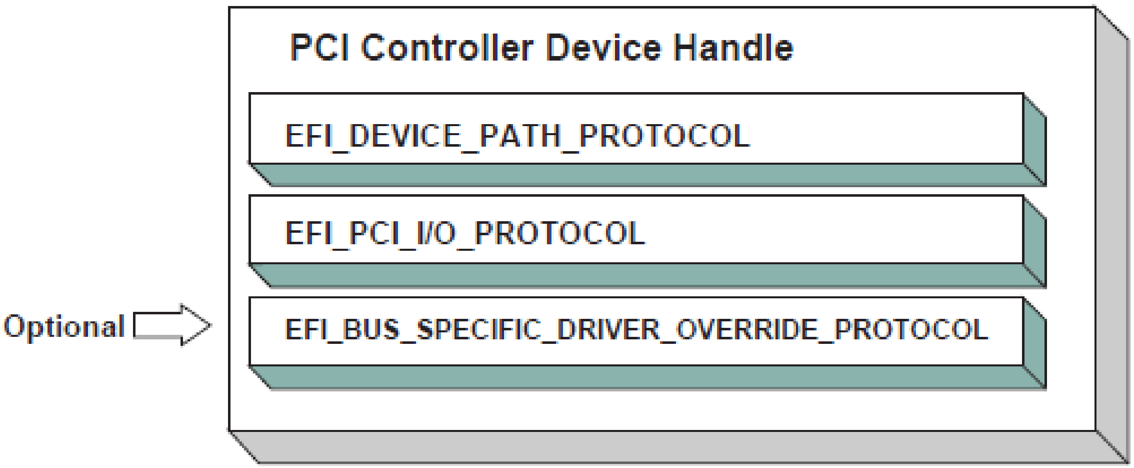

Fig. 14.13: Child Handle Created by a PCI Bus Driver

A PCI Bus Driver must perform several steps to manage a PCI Host Bus Controller, as follows:

- Initialize the PCI Host Bus Controller.
- If the PCI buses have not been initialized by a previous agent, perform PCI Enumeration on all the PCI Root Bridges that the PCI Host Bus Controller contains. This involves assigning a PCI bus number, allocating PCI I/O resources, PCI Memory resources, and PCI Prefetchable Memory resources.
- Discover all the PCI Controllers on all the PCI Root Bridges. If a PCI Controller is a PCI to PCI Bridge, then the I/O and Memory bits in the Control register of the PCI Configuration Header should be placed in the enabled state. The Bus Master bit in the Control Register may be enabled by default or enabled or disabled based on the needs of downstream devices for DMA access during the boot process. The PCI Bus Driver should disable the I/O, Memory, and Bus Master bits for PCI Controllers that respond to legacy ISA resources (e.g. VGA). It is a PCI Device Driver's responsibility to enable the I/O, Memory, and Bus Master bits (if they are not already enabled by the PCI bus driver) of the Control register as required with a call to the *EFI_PCI_IO_PROTOCOL.Attributes()* service when the PCI Device Driver is started. A similar call to the Attributes() service should be made when the PCI Device Driver is stopped to restore original Attributes() state, including the I/O, Memory, and Bus Master bits of the Control register.
- Create a device handle for each PCI Controller found. If a request is being made to start only one PCI Controller, then only create one device handle.
- Install a Device Path Protocol instance and a PCI I/O Protocol instance on the device handle created for each PCI Controller.
- If the PCI Controller has a PCI Option ROM, then allocate a memory buffer that is the same size as the PCI Option ROM, and copy the PCI Option ROM contents to the memory buffer.
- If the PCI Option ROM contains any UEFI drivers, then attach a Bus Specific Driver Override Protocol to the device handle of the PCI Controller that is associated with the PCI Option ROM.

The *EFI_DRIVER_BINDING_PROTOCOL.Stop()* function tells the PCI Bus Driver to stop managing a PCI Host Bus Controller. The *Stop()* function can destroy one or more of the device handles that were created on a previous call to *EFI_DRIVER_BINDING_PROTOCOL.Start()*. If all of the child device handles have been destroyed, then *Stop()* will place the PCI Host Bus Controller in a quiescent state. The functionality of *Stop()* mirrors *Start()* , as follows:

1. Complete all outstanding transactions to the PCIHost Bus Controller.
2. If the PCI Host Bus Controller is being stopped, then place it in a quiescent state.

3. If one or more child handles are being destroyed, then:
    a. Uninstall all the protocols from the device handles for the PCI Controllers found in Start().
    b. Free any memory buffers allocated for PCI Option ROMs.
    c. Destroy the device handles for the PCI controllers created in Start().

14.3.7 PCI Enumeration

The PCI Enumeration process is a platform-specific operation that depends on the properties of the chipset that produces the PCI bus. As a result, details on PCI Enumeration are outside the scope of this document. A PCI Bus Driver requires that PCI Enumeration has been performed, so it either needs to have been done prior to the PCI Bus Driver starting, or it must be part of the PCI Bus Driver's implementation.

14.3.8 PCI Device Drivers

PCI Device Drivers manage PCI Controllers. Device handles for PCI Controllers are created by PCI Bus Drivers. A PCI Device Driver is not allowed to create any new device handles. Instead, it attaches protocol instance to the device handle of the PCI Controller. These protocol instances are I/O abstractions that allow the PCI Controller to be used in the preboot environment. The most common I/O abstractions are used to boot an EFI compliant OS.

14.3.9 Driver Binding Protocol for PCI Device Drivers

The Driver Binding Protocol contains three services. These are *EFI_DRIVER_BINDING_PROTOCOL.Supported()* , *EFI_DRIVER_BINDING_PROTOCOL.Start()*, and *EFI_DRIVER_BINDING_PROTOCOL.Stop()*. *Supported()* tests to see if the PCI Device Driver can manage a device handle. A PCI Device Driver can only manage device handles that contain the Device Path Protocol and the PCI I//O Protocol, so a PCI Device Driver must look for these two protocols on the device handle that is being tested. In addition, it needs to check to see if the device handle represents a PCI Controller that the PCI Device Driver knows how to manage. This is typically done by using the services of the PCI I/O Protocol to read the PCI Configuration Header for the PCI Controller, and looking at the *VendorId* , *DeviceId* , and *SubsystemId* fields.

The *Start()* function tells the PCI Device Driver to start managing a PCI Controller. A PCI Device Driver is not allowed to create any new device handles. Instead, it installs one or more addition protocol instances on the device handle for the PCI Controller. A PCI Device Driver is not allowed to modify the resources allocated to a PCI Controller. These resource allocations are owned by the PCI Bus Driver or some other firmware component that initialized the PCI Bus prior to the execution of the PCI Bus Driver. This means that the PCI BARs (Base Address Registers) and the configuration of any PCI to PCI bridge controllers must not be modified by a PCI Device Driver.A PCI Bus Driver will leave a PCI Device in a disabled safe initial state. A PCI Device Driver should save the original Attributes() state. It is a PCI Device Driver's responsibility to call Attributes() to enable the I/O, Memory, and Bus Master decodes if they are not already enabled by the PCI bus driver.

The *EFI_DRIVER_BINDING_PROTOCOL.Stop()* function mirrors the *EFI_DRIVER_BINDING_PROTOCOL.Start()* function, so the *Stop()* function completes any outstanding transactions to the PCI Controller and removes the protocol interfaces that were installed in *Start()*. The Figure below shows the device handle for a PCI Controller before and after *Start()* is called. In this example, a PCI Device Driver is adding the Block I/O Protocol to the device handle for the PCI Controller. It is also a PCI Device Driver's responsibility to restore original Attributes() state, including the I/O, Memory, and Bus Master decodes by calling *EFI_PCI_IO_PROTOCOL.Attributes()* .

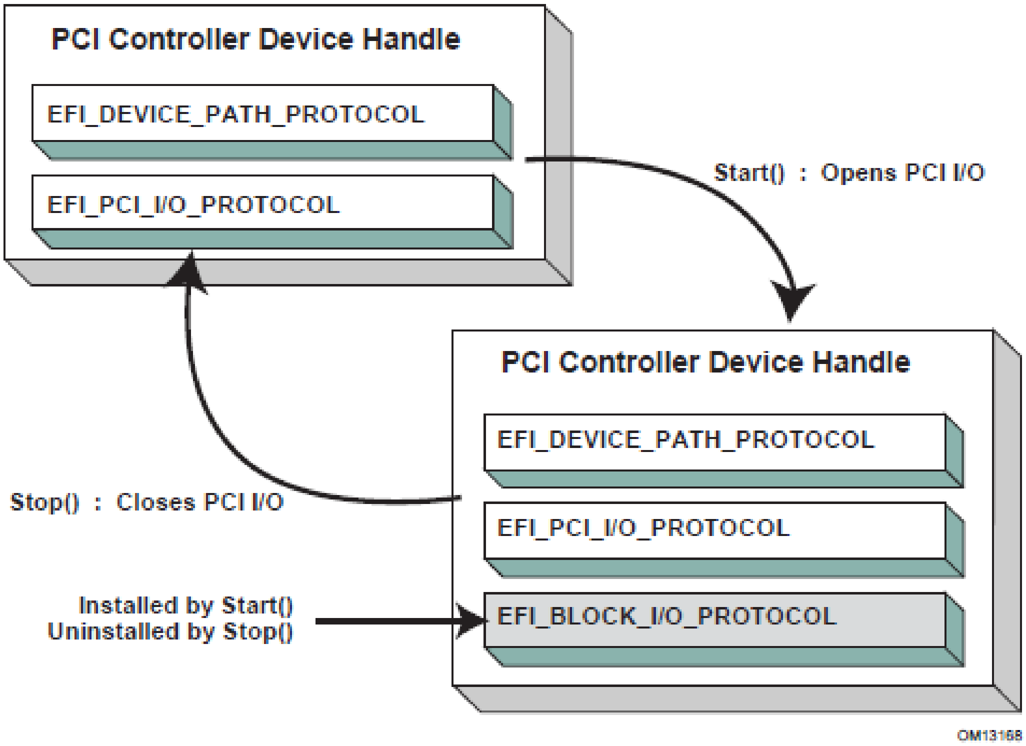

Fig. 14.14: Connecting a PCI Device Driver

14.4 EFI PCI I/O Protocol

This section provides a detailed description of the *EFI PCI I/O Protocol* . This protocol is used by code, typically drivers, running in the EFI boot services environment to access memory and I/O on a PCI controller. In particular, functions for managing devices on PCI buses are defined here.

The interfaces provided in the *EFI_PCI_IO_PROTOCOL* are for performing basic operations to memory, I/O, and PCI configuration space. The system provides abstracted access to basic system resources to allow a driver to have a programmatic method to access these basic system resources. The main goal of this protocol is to provide an abstraction that simplifies the writing of device drivers for PCI devices. This goal is accomplished by providing the following features:

- A driver model that does not require the driver to search the PCI busses for devices to manage. Instead, drivers are provided the location of the device to manage or have the capability to be notified when a PCI controller is discovered.
- A device driver model that abstracts the I/O addresses, Memory addresses, and PCI Configuration addresses from the PCI device driver. Instead, BAR (Base Address Register) relative addressing is used for I/O and Memory accesses, and device relative addressing is used for PCI Configuration accesses. The BAR relative addressing is specified in the PCI I/O services as a BAR index. A PCI controller may contain a combination of 32-bit and 64-bit BARs. The BAR index represents the logical BAR number in the standard PCI configuration header starting from the first BAR. The BAR index does not represent an offset into the standard PCI Configuration Header because those offsets will vary depending on the combination and order of 32-bit and 64-bit BARs.
- The Device Path for the PCI device can be obtained from the same device handle that the EFI_PCI_IO_PROTOCOL resides.
- The PCI Segment, PCI Bus Number, PCI Device Number, and PCI Function Number of the PCI device if they are required. The general idea is to abstract these details away from the PCI device driver. However, if these details are required, then they are available.
- Details on any nonstandard address decoding that is not covered by the PCI device's Base Address Registers.
- Access to the PCI Root Bridge I/O Protocol for the PCI Host Bus for which the PCI device is a member.
- A copy of the PCI Option ROM if it is present in system memory.
- Functions to perform bus mastering DMA. This includes both packet based DMA and common buffer DMA.

14.4.1 EFI_PCI_IO_PROTOCOL

Summary

Provides the basic Memory, I/O, PCI configuration, and DMA interfaces that a driver uses to access its PCI controller.

GUID

```
#define EFI_PCI_IO_PROTOCOL_GUID \
 {0x4cf5b200,0x68b8,0x4ca5,\
   {0x9e,0xec,0xb2,0x3e,0x3f,0x50,0x02,0x9a}}
```

Protocol Interface Structure

```
typedef struct  _EFI_PCI_IO_PROTOCOL {
  EFI_PCI_IO_PROTOCOL_POLL_IO_MEM          PollMem;
  EFI_PCI_IO_PROTOCOL_POLL_IO_MEM          PollIo;
  EFI_PCI_IO_PROTOCOL_ACCESS               Mem;
```

(continues on next page)

(continued from previous page)

```
  EFI_PCI_IO_PROTOCOL_ACCESS              Io;
  EFI_PCI_IO_PROTOCOL_CONFIG_ACCESS       Pci;
  EFI_PCI_IO_PROTOCOL_COPY_MEM            CopyMem;
  EFI_PCI_IO_PROTOCOL_MAP                 Map;
  EFI_PCI_IO_PROTOCOL_UNMAP               Unmap;
  EFI_PCI_IO_PROTOCOL_ALLOCATE_BUFFER     AllocateBuffer;
  EFI_PCI_IO_PROTOCOL_FREE_BUFFER         FreeBuffer;
  EFI_PCI_IO_PROTOCOL_FLUSH               Flush;
  EFI_PCI_IO_PROTOCOL_GET_LOCATION        GetLocation;
  EFI_PCI_IO_PROTOCOL_ATTRIBUTES          Attributes;
  EFI_PCI_IO_PROTOCOL_GET_BAR_ATTRIBUTES  GetBarAttributes;
  EFI_PCI_IO_PROTOCOL_SET_BAR_ATTRIBUTES  SetBarAttributes;
  UINT64                                  RomSize;
  VOID                                    *RomImage;
} EFI_PCI_IO_PROTOCOL;
```

Parameters

PollMem
Polls an address in PCI memory space until an exit condition is met, or a timeout occurs. *EFI_PCI_IO_PROTOCOL.PollMem()* function description.

PollIo
Polls an address in PCI I/O space until an exit condition is met, or a timeout occurs. *EFI_PCI_IO_PROTOCOL.PollIo()* function description.

Mem.Read
Allows BAR relative reads to PCI memory space. *EFI_PCI_IO_PROTOCOL.MEM.READ()* function description.

Mem.Write
Allows BAR relative writes to PCI memory space. See the Mem.Write() *EFI_PCI_IO_PROTOCOL.MEM.WRITE()* function description.

Io.Read
Allows BAR relative reads to PCI I/O space. See the Io.Read() *EFI_PCI_IO_PROTOCOL.Io.Read()* function description.

Io.Write
Allows BAR relative writes to PCI I/O space. See the Io.Write() *EFI_PCI_IO_PROTOCOL.Io.Write()* function description.

Pci.Read
Allows PCI controller relative reads to PCI configuration space. See the Pci.Read() *EFI_PCI_IO_PROTOCOL.Pci.Read()* function description.

Pci.Write
Allows PCI controller relative writes to PCI configuration space. See the Pci.Write() *EFI_PCI_IO_PROTOCOL.Pci.Write()* function description.

CopyMem
Allows one region of PCI memory space to be copied to another region of PCI memory space. *EFI_PCI_IO_PROTOCOL.CopyMem()* function description.

Map
Provides the PCI controller-specific address needed to access system memory for DMA. See the *EFI_PCI_IO_PROTOCOL.Map()* function description.

Unmap
Releases any resources allocated by Map(). See the *EFI-PCI-IO-PROTOCOL-Unmap()* function description.

AllocateBuffer
Allocates pages that are suitable for a common buffer mapping. See the *EFI_PCI_IO_PROTOCOL.AllocateBuffer()* function description.

FreeBuffer
Frees pages that were allocated with AllocateBuffer(). See the *EFI_PCI_IO_PROTOCOL.FreeBuffer()* function description.

Flush
Flushes all PCI posted write transactions to system memory. See the *EFI_PCI_IO_PROTOCOL.Flush()* function description.

GetLocation
Retrieves this PCI controller's current PCI bus number, device number, and function number. See the *EFI_PCI_IO_PROTOCOL.GetLocation()* function description.

Attributes
Performs an operation on the attributes that this PCI controller supports. The operations include getting the set of supported attributes, retrieving the current attributes, setting the current attributes, enabling attributes, and disabling attributes. See the *EFI_PCI_IO_PROTOCOL.Attributes()* function description.

GetBarAttributes
Gets the attributes that this PCI controller supports setting on a BAR using *EFI_PCI_IO_PROTOCOL.SetBarAttributes()* , and retrieves the list of resource descriptors for a BAR. See the *EFI_PCI_IO_PROTOCOL.GetBarAttributes()* function description.

SetBarAttributes
Sets the attributes for a range of a BAR on a PCI controller. See the SetBarAttributes() function description.

RomSize
The size, in bytes, of the ROM image.

RomImage
A pointer to the in memory copy of the ROM image. The PCI Bus Driver is responsible for allocating memory for the ROM image, and copying the contents of the ROM to memory. The contents of this buffer are either from the PCI option ROM that can be accessed through the ROM BAR of the PCI controller, or it is from a platform-specific location. The *EFI_PCI_IO_PROTOCOL.Attributes()* function can be used to determine from which of these two sources the RomImage buffer was initialized.

```

EFI_PCI_IO_ATTRIBUTE_ISA_IO_16

If this bit is set, then the PCI I/O cycles between 0x100 and 0x3FF are forwarded to the PCI controller using a 16-bit address decoder on address bits 0..15. Address bits 16..31 must be zero. This bit is used to forward I/O cycles for legacy ISA devices. If this bit is set, then the PCI Host Bus Controller and all the PCI to PCI bridges between the PCI Host Bus Controller and the PCI Controller are configured to forward these PCI I/O cycles. This bit may not be combined with *EFI_PCI_IO_ATTRIBUTE_ISA_IO*.

EFI_PCI_IO_ATTRIBUTE_VGA_PALETTE_IO_16

If this bit is set, then the PCI I/O write cycles for 0x3C6, 0x3C8, and 0x3C9 are forwarded to the PCI controller using a 16-bit address decoder on address bits 0..15. Address bits 16..31 must be zero. This bit is used to forward I/O write cycles to the VGA palette registers on a PCI controller. If this bit is set, then the PCI Host Bus Controller and all the PCI to PCI bridges between the PCI Host Bus Controller and the PCI Controller are configured to forward these PCI I/O cycles. This bit may not be combined with *EFI_PCI_IO_ATTRIBUTE_VGA_IO* or *EFI_PCI_IO_ATTRIBUTE_VGA_PALETTE_IO*.

EFI_PCI_IO_ATTRIBUTE_VGA_IO_16

If this bit is set, then the PCI I/O cycles in the ranges 0x3B0-0x3BB and 0x3C0-0x3DF are forwarded to the PCI controller using a 16-bit address decoder on address bits 0..15. Address bits 16..31 must be zero. This bit is used to forward I/O cycles for a VGA controller to a PCI controller. If this bit is set, then the PCI Host Bus Controller and all the PCI to PCI bridges between the PCI Host Bus Controller and the PCI Controller are configured to forward these PCI I/O cycles. This bit may not be combined with *EFI_PCI_IO_ATTRIBUTE_VGA_IO* or *EFI_PCI_IO_ATTRIBUTE_VGA_PALETTE_IO*. Because *EFI_PCI_IO_ATTRIBUTE_VGA_IO_16* also includes the I/O range described by *EFI_PCI_IO_ATTRIBUTE_VGA_PALETTE_IO_16* , the *EFI_PCI_IO_ATTRIBUTE_VGA_PALETTE_IO_16* bit is ignored if *EFI_PCI_IO_ATTRIBUTE_VGA_IO_16* is set.

EFI_PCI_IO_ATTRIBUTE_ISA_MOTHERBOARD_IO

If this bit is set, then the PCI I/O cycles between 0x00000000 and 0x000000FF are forwarded to the PCI controller. This bit is used to forward I/O cycles for ISA motherboard devices. If this bit is set, then the PCI Host Bus Controller and all the PCI to PCI bridges between the PCI Host Bus Controller and the PCI Controller are configured to forward these PCI I/O cycles.

EFI_PCI_IO_ATTRIBUTE_ISA_IO

If this bit is set, then the PCI I/O cycles between 0x100 and 0x3FF are forwarded to the PCI controller using a 10-bit address decoder on address bits 0..9. Address bits 10..15 are not decoded, and address bits 16..31 must be zero. This bit is used to forward I/O cycles for legacy ISA devices. If this bit is set, then the PCI Host Bus Controller and all the PCI to PCI bridges between the PCI Host Bus Controller and the PCI Controller are configured to forward these PCI I/O cycles.

EFI_PCI_IO_ATTRIBUTE_VGA_PALETTE_IO

If this bit is set, then the PCI I/O write cycles for 0x3C6, 0x3C8, and 0x3C9 are forwarded to the PCI controller using a 10-bit address decoder on address bits 0..9. Address bits 10..15 are not decoded, and address bits 16..31 must be zero. This bit is used to forward I/O write cycles to the VGA palette registers on a PCI controller. If this bit is set, then the PCI Host Bus Controller and all the PCI to PCI bridges between the PCI Host Bus Controller and the PCI Controller are configured to forward these PCI I/O cycles.

EFI_PCI_IO_ATTRIBUTE_VGA_MEMORY

If this bit is set, then the PCI memory cycles between 0xA0000 and 0xBFFFF are forwarded to the PCI controller. This bit is used to forward memory cycles for a VGA frame buffer on a PCI controller. If this bit is set, then the PCI Host Bus Controller and all the PCI to PCI bridges between the PCI Host Bus Controller and the PCI Controller are configured to forward these PCI Memory cycles.

EFI_PCI_IO_ATTRIBUTE_VGA_IO

If this bit is set, then the PCI I/O cycles in the ranges 0x3B0-0x3BB and 0x3C0-0x3DF are forwarded to the PCI controller using a 10-bit address decoder on address bits 0..9. Address bits 10..15 are not decoded, and the address bits 16..31 must be zero. This bit is used to forward I/O cycles for a VGA controller to a PCI controller. If this bit is set, then the PCI Host Bus Controller and all the PCI to PCI bridges between the PCI Host Bus Controller and the PCI Controller are configured to forward these PCI I/O cycles. Since EFI_PCI_IO_ATTRIBUTE_VGA_IO also includes the I/O range described by EFI_PCI_IO_ATTRIBUTE_VGA_PALETTE_IO, the EFI_PCI_IO_ATTRIBUTE_VGA_PALETTE_IO bit is ignored if EFI_PCI_IO_ATTRIBUTE_VGA_IO is set.

EFI_PCI_IO_ATTRIBUTE_IDE_PRIMARY_IO

If this bit is set, then the PCI I/O cycles in the ranges 0x1F0-0x1F7 and 0x3F6-0x3F7 are forwarded to a PCI controller using a 16-bit address decoder on address bits 0..15. Address bits 16..31 must be zero. This bit is used to forward I/O cycles for a Primary IDE controller to a PCI controller. If this bit is set, then the PCI Host Bus Controller and all the PCI to PCI bridges between the PCI Host Bus Controller and the PCI Controller are configured to forward these PCI I/O cycles.

EFI_PCI_IO_ATTRIBUTE_IDE_SECONDARY_IO

If this bit is set, then the PCI I/O cycles in the ranges 0x170-0x177 and 0x376-0x377 are forwarded to a PCI controller using a 16-bit address decoder on address bits 0..15. Address bits 16..31 must be zero. This bit is used to forward I/O cycles for a Secondary IDE controller to a PCI controller. If this bit is set, then the PCI Host Bus Controller and all the PCI to PCI bridges between the PCI Host Bus Controller and the PCI Controller are configured to forward these PCI I/O cycles.

EFI_PCI_IO_ATTRIBUTE_MEMORY_WRITE_COMBINE

If this bit is set, then this platform supports changing the attributes of a PCI memory range so that the memory range is accessed in a write combining mode. This bit is used to improve the write performance to a memory buffer on a PCI controller. By default, PCI memory ranges are not accessed in a write combining mode.

EFI_PCI_IO_ATTRIBUTE_MEMORY_CACHED

If this bit is set, then this platform supports changing the attributes of a PCI memory range so that the memory range is accessed in a cached mode. By default, PCI memory ranges are accessed noncached.

EFI_PCI_IO_ATTRIBUTE_IO

If this bit is set, then the PCI device will decode the PCI I/O cycles that the device is configured to decode.

EFI_PCI_IO_ATTRIBUTE_MEMORY

If this bit is set, then the PCI device will decode the PCI Memory cycles that the device is configured to decode.

EFI_PCI_IO_ATTRIBUTE_BUS_MASTER

If this bit is set, then the PCI device is allowed to act as a bus master on the PCI bus.

EFI_PCI_IO_ATTRIBUTE_MEMORY_DISABLE

If this bit is set, then this platform supports changing the attributes of a PCI memory range so that the memory range is disabled, and can no longer be accessed. By default, all PCI memory ranges are enabled.

EFI_PCI_IO_ATTRIBUTE_EMBEDDED_DEVICE

If this bit is set, then the PCI controller is an embedded device that is typically a component on the system board. If this bit is clear, then this PCI controller is part of an adapter that is populating one of the systems PCI slots.

EFI_PCI_IO_ATTRIBUTE_EMBEDDED_ROM

If this bit is set, then the PCI option ROM described by the *RomImage* and *RomSize* fields is not from ROM BAR of the PCI controller. If this bit is clear, then the *RomImage* and *RomSize* fields were initialized based on the PCI option ROM found through the ROM BAR of the PCI controller.

EFI_PCI_IO_ATTRIBUTE_DUAL_ADDRESS_CYCLE

If this bit is set, then the PCI controller is capable of producing PCI Dual Address Cycles, so it is able to access a 64-bit address space. If this bit is not set, then the PCI controller is not capable of producing PCI Dual Address Cycles, so it is only able to access a 32-bit address space.

If this bit is set, then the PCI Host Bus Controller and all the PCI to PCI bridges between the PCI Host Bus Controller and the PCI Controller are capable of producing PCI Dual Address Cycles. If any of them is not capable of producing PCI Dual Address Cycles, attempt to perform Set or Enable operation using *Attributes()* function with this bit set will fail with the *EFI_UNSUPPORTED* error code.

```
//*******************************************************
// EFI_PCI_IO_PROTOCOL_OPERATION
//*******************************************************
typedef enum {
  EfiPciIoOperationBusMasterRead,
  EfiPciIoOperationBusMasterWrite,
  EfiPciIoOperationBusMasterCommonBuffer,
  EfiPciIoOperationMaximum
}   EFI_PCI_IO_PROTOCOL_OPERATION;
```

EfiPciIoOperationBusMasterRead

A read operation from system memory by a bus master.

EfiPciIoOperationBusMasterWrite

A write operation to system memory by a bus master.

EfiPciIoOperationBusMasterCommonBuffer

Provides both read and write access to system memory by both the processor and a bus master. The buffer is coherent from both the processor's and the bus master's point of view.

Description

The *EFI_PCI_IO_PROTOCOL* provides the basic Memory, I/O, PCI configuration, and DMA interfaces that are used to abstract accesses to PCI controllers. There is one *EFI_PCI_IO_PROTOCOL* instance for each PCI controller on a PCI bus. A device driver that wishes to manage a PCI controller in a system will have to retrieve the *EFI_PCI_IO_PROTOCOL* instance that is associated with the PCI controller. A device handle for a PCI controller will minimally contain an *EFI Device Path Protocol* instance and an *EFI_PCI_IO_PROTOCOL* instance.

Bus mastering PCI controllers can use the DMA services for DMA operations. There are three basic types of bus mastering DMA that is supported by this protocol. These are DMA reads by a bus master, DMA writes by a bus master, and common buffer DMA. The DMA read and write operations may need to be broken into smaller chunks. The caller of *EFI_PCI_IO_PROTOCOL.Map()* must pay attention to the number of bytes that were mapped, and if required, loop until the entire buffer has been transferred. The following is a list of the different bus mastering DMA operations that are supported, and the sequence of *EFI_PCI_IO_PROTOCOL* interfaces that are used for each DMA operation type.

DMA Bus Master Read Operation

Call *EFI_PCI_IO_PROTOCOL.Map()* for EfiPciIoOperationBusMasterRead.

Program the DMA Bus Master with the *DeviceAddress* returned by *Map()*.

Start the DMA Bus Master.

Wait for DMA Bus Master to complete the read operation.

Call *EFI-PCI-IO-PROTOCOL-Unmap()*.

DMA Bus Master Write Operation

Call Map() for EfiPciOperationBusMasterWrite.

Program the DMA Bus Master with the *DeviceAddress* returned by *Map()*.

Start the DMA Bus Master.

Wait for DMA Bus Master to complete the write operation.

Perform a PCI controller specific read transaction to flush all PCI write buffers (See PCI Specification Section 3.2.5.2).

Call *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.Flush()* .

Call *Unmap()*.

DMA Bus Master Common Buffer Operation

Call *EFI_PCI_IO_PROTOCOL.AllocateBuffer()* . to allocate a common buffer.

Call Map() for EfiPciIoOperationBusMasterCommonBuffer.

Program the DMA Bus Master with the *DeviceAddress* returned by *Map()*.

The common buffer can now be accessed equally by the processor and the DMA bus master.

Call Unmap().

Call *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL.FreeBuffer()* .

14.4.2 EFI_PCI_IO_PROTOCOL.PollMem()

Summary

Reads from the memory space of a PCI controller. Returns when either the polling exit criteria is satisfied or after a defined duration.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_IO_PROTOCOL_POLL_IO_MEM) (
  IN EFI_PCI_IO_PROTOCOL             *This,
  IN EFI_PCI_IO_PROTOCOL_WIDTH       Width,
  IN UINT8                           BarIndex,
  IN UINT64                          Offset,
  IN UINT64                          Mask,
  IN UINT64                          Value,
  IN UINT64                          Delay,
  OUT UINT64                         *Result
);
```

Parameters

This

A pointer to the *EFI PCI I/O Protocol* instance. Type EFI_PCI_IO_PROTOCOL is defined in *EFI PCI I/O Protocol*.

Width

Signifies the width of the memory operations, defined in *EFI PCI I/O Protocol* .

BarIndex

The BAR index of the standard PCI Configuration header to use as the base address for the memory operation to perform. This allows all drivers to use BAR relative addressing. The legal range for this field is 0..5. However, the value **EFI_PCI_IO_PASS_THROUGH_BAR** can be used to bypass the BAR relative addressing and pass *Offset* to the PCI Root Bridge I/O Protocol unchanged. Type EFI_PCI_IO_PASS_THROUGH_BAR is defined in *EFI_PCI_IO_Protocol* .

Offset

The offset within the selected BAR to start the memory operation.

Mask

Mask used for the polling criteria. Bytes above Width in Mask are ignored. The bits in the bytes below Width which are zero in Mask are ignored when polling the memory address.

Value

The comparison value used for the polling exit criteria.

Delay

The number of 100 ns units to poll. Note that timer available may be of poorer granularity.

Result

Pointer to the last value read from the memory location.

Description

This function provides a standard way to poll a PCI memory location. A PCI memory read operation is performed at the PCI memory address specified by *BarIndex* and *Offset* for the width specified by *Width*. The result of this PCI memory read operation is stored in *Result*. This PCI memory read operation is repeated until either a timeout of *Delay* 100 ns units has expired, or (*Result & Mask)* is equal to *Value*.

This function will always perform at least one memory access no matter how small *Delay* may be. If *Delay* is 0, then *Result* will be returned with a status of *EFI_SUCCESS* even if *Result* does not match the exit criteria. If *Delay* expires, then *EFI_TIMEOUT* is returned.

If *Width* is not *EfiPciIoWidthUint8* , *EfiPciIoWidthUint16* , *EfiPciIoWidthUint32* , or *EfiPciIoWidthUint64* , then *EFI_INVALID_PARAMETER* is returned.

The memory operations are carried out exactly as requested. The caller is responsible for satisfying any alignment and memory width restrictions that a PCI controller on a platform might require. For example on some platforms, width requests of *EfiPciIoWidthUint64* do not work.

All the PCI transactions generated by this function are guaranteed to be completed before this function returns. However, if the memory mapped I/O region being accessed by this function has the *EFI_PCI_IO_ATTRIBUTE_MEMORY_CACHED* attribute set, then the transactions will follow the ordering rules defined by the processor architecture.

Status Codes Returned

EFI_SUCCESS	The last data returned from the access matched the poll exit criteria.
EFI_INVALID_PARAMETER	Width is invalid.
EFI_INVALID_PARAMETER	Result is **NULL**.
EFI_UNSUPPORTED	BarIndex not valid for this PCI controller.
EFI_UNSUPPORTED	Offset is not valid for the BarIndex of this PCI controller.
EFI_TIMEOUT	Delay expired before a match occurred.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.

14.4.3 EFI_PCI_IO_PROTOCOL.PollIo()

Summary

Reads from the I/O space of a PCI controller. Returns when either the polling exit criteria is satisfied or after a defined duration.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_IO_PROTOCOL_POLL_IO_MEM) (
  IN EFI_PCI_IO_PROTOCOL             *This,
  IN EFI_PCI_IO_PROTOCOL_WIDTH       Width,
  IN UINT8                           BarIndex,
  IN UINT64                          Offset,
  IN UINT64                          Mask,
  IN UINT64                          Value,
  IN UINT64                          Delay,
  OUT UINT64                         *Result
);
```

Parameters

This

A pointer to the *EFI_PCI_IO_PROTOCOL* instance. Type EFI_PCI_IO_PROTOCOL is defined in See *EFI PCI I/O Protocol*.

Width

Signifies the width of the I/O operations. Type EFI_PCI_IO_PROTOCOL_WIDTH, defined in *EFI PCI I/O Protocol* .

BarIndex

The BAR index of the standard PCI Configuration header to use as the base address for the I/O operation to perform. This allows all drivers to use BAR relative addressing. The legal range for this field is 0..5. However, the value **EFI_PCI_IO_PASS_THROUGH_BAR** can be used to bypass the BAR relative addressing and pass *Offset* to the PCI Root Bridge I/O Protocol unchanged. Type EFI_PCI_IO_PASS_THROUGH_BAR is defined in *EFI_PCI_IO_Protocol* .

Offset

The offset within the selected BAR to start the I/O operation.

Mask

Mask used for the polling criteria. Bytes above Width in Mask are ignored. The bits in the bytes below Width which are zero in Mask are ignored when polling the I/O address.

Value

The comparison value used for the polling exit criteria.

Delay

The number of 100 ns units to poll. Note that timer available may be of poorer granularity.

Result

Pointer to the last value read from the memory location.

Description

This function provides a standard way to poll a PCI I/O location. A PCI I/O read operation is performed at the PCI I/O address specified by *BarIndex* and *Offset* for the width specified by *Width*. The result of this PCI I/O read operation is stored in *Result*. This PCI I/O read operation is repeated until either a timeout of *Delay* 100 ns units has expired, or (*Result & Mask*) is equal to *Value*.

This function will always perform at least one I/O access no matter how small *Delay* may be. If *Delay* is 0, then *Result* will be returned with a status of *EFI_SUCCESS* even if *Result* does not match the exit criteria. If *Delay* expires, then *EFI_TIMEOUT* is returned.

If *Width* is not *EfiPciIoWidthUint8* , *EfiPciIoWidthUint16* , *EfiPciIoWidthUint32* , or *EfiPciIoWidthUint64* , then *EFI_INVALID_PARAMETER* is returned.

The I/O operations are carried out exactly as requested. The caller is responsible satisfying any alignment and I/O width restrictions that the PCI controller on a platform might require. For example on some platforms, width requests of *EfiPciIoWidthUint64* do not work.

All the PCI read transactions generated by this function are guaranteed to be completed before this function returns.

Status Codes Returned

EFI_SUCCESS	The last data returned from the access matched the poll exit criteria.
EFI_INVALID_PARAMETER	Width is invalid.
EFI_INVALID_PARAMETER	Result is *NULL*.
EFI_UNSUPPORTED	BarIndex not valid for this PCI controller.
EFI_UNSUPPORTED	Offset is not valid for the PCI BAR specified by BarIndex.
EFI_TIMEOUT	Delay expired before a match occurred.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.

14.4.4 EFI_PCI_IO_PROTOCOL.Mem.Read()

14.4.5 EFI_PCI_IO_PROTOCOL.Mem.Write()

Summary

Enable a PCI driver to access PCI controller registers in the PCI memory space.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_IO_PROTOCOL_MEM) (
  IN EFI_PCI_IO_PROTOCOL                   *This,
  IN EFI_PCI_IO_PROTOCOL_WIDTH             Width,
  IN UINT8                                 BarIndex,
  IN UINT64                                Offset,
  IN UINTN                                 Count,
  IN OUT VOID                              *Buffer
  );
```

Parameters

This
A pointer to the See *EFI_PCI_IO_PROTOCOL* instance. Type EFI_PCI_IO_PROTOCOL is defined in *EFI PCI I/O Protocol* .

Width
Signifies the width of the memory operations. Type EFI_PCI_IO_PROTOCOL_WIDTH, defined in *EFI PCI I/O Protocol* .

BarIndex
The BAR index of the standard PCI Configuration header to use as the base address for the memory operation to perform. This allows all drivers to use BAR relative addressing. The legal range for this field is 0..5. However, the value **EFI_PCI_IO_PASS_THROUGH_BAR** can be used to bypass the BAR relative addressing and pass *Offset* to the PCI Root Bridge I/O Protocol unchanged. Type EFI_PCI_IO_PASS_THROUGH_BAR is defined in *EFI_PCI_IO_Protocol* .

Offset
The offset within the selected BAR to start the memory operation.

Count
The number of memory operations to perform. Bytes moved is Width size * Count, starting at Offset.

Buffer
For read operations, the destination buffer to store the results. For write operations, the source buffer to write data from.

Description

The *Mem.Read()* , and *Mem.Write()* functions enable a driver to access controller registers in the PCI memory space.

The I/O operations are carried out exactly as requested. The caller is responsible for any alignment and I/O width issues which the bus, device, platform, or type of I/O might require. For example on some platforms, width requests of *EfiPciIoWidthUint64* do not work.

If *Width* is *EfiPciIoWidthUint8* , *EfiPciIoWidthUint16* , *EfiPciIoWidthUint32* , or *EfiPciIoWidthUint64* , then both *Address* and *Buffer* are incremented for each of the *Count* operations performed.

If *Width* is *EfiPciIoWidthFifoUint8* , *EfiPciIoWidthFifoUint16* , *EfiPciIoWidthFifoUint32* , or *EfiPciIoWidthFifoUint64* , then only *Buffer* is incremented for each of the *Count* operations performed. The read or write operation is performed *Count* times on the same *Address*.

If *Width* is *EfiPciIoWidthFillUint8* , *EfiPciIoWidthFillUint16* , *EfiPciIoWidthFillUint32* , or *EfiPciIoWidthFillUint64* , then only *Address* is incremented for each of the *Count* operations performed. The read or write operation is performed *Count* times from the first element of *Buffer*.

All the PCI transactions generated by this function are guaranteed to be completed before this function returns. All the PCI write transactions generated by this function will follow the write ordering and completion rules defined in the PCI Specification. However, if the memory-mapped I/O region being accessed by this function has the *EFI_PCI_IO_ATTRIBUTE_MEMORY_CACHED* attribute set, then the transactions will follow the ordering rules defined by the processor architecture.

Status Codes Returned

EFI_SUCCESS	The data was read from or written to the PCI controller.
EFI_INVALID_PARAMETER	Width is invalid.
EFI_INVALID_PARAMETER	Buffer is **NULL**.
EFI_UNSUPPORTED	BarIndex not valid for this PCI controller.
EFI_UNSUPPORTED	The address range specified by Offset, Width, and Count is not valid for the PCI BAR specified by BarIndex.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.

14.4.6 EFI_PCI_IO_PROTOCOL.Io.Read()

14.4.7 EFI_PCI_IO_PROTOCOL.Io.Write()

Summary

Enable a PCI driver to access PCI controller registers in the PCI I/O space.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_IO_PROTOCOL_MEM) (
  IN EFI_PCI_IO_PROTOCOL                     *This,
  IN EFI_PCI_IO_PROTOCOL_WIDTH               Width,
  IN UINT8                                   BarIndex,
  IN UINT64                                  Offset,
  IN UINTN                                   Count,
  IN OUT VOID                                *Buffer
);
```

Parameters

This

A pointer to the *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL* instance. Type EFI_PCI_IO_PROTOCOL is defined in *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL* .

Width

Signifies the width of the memory operations. Type EFI_PCI_IO_PROTOCOL_WIDTH, defined in *EFI PCI I/O Protocol* .

BarIndex

The BAR index of the standard PCI Configuration header to use as the base address for the I/O operation to perform. This allows all drivers to use BAR relative addressing. The legal range for this field is 0..5. However, the value **EFI_PCI_IO_PASS_THROUGH_BAR** can be used to bypass the BAR relative addressing and pass *Offset* to the PCI Root Bridge I/O Protocol unchanged. Type EFI_PCI_IO_PASS_THROUGH_BAR is defined in *EFI_PCI_IO_Protocol* .

Offset

The offset within the selected BAR to start the I/O operation.

Count

The number of I/O operations to perform. Bytes moved is Width size * Count, starting at Offset.

Buffer

For read operations, the destination buffer to store the results. For write operations, the source buffer to write data from.

Description

The *Io.Read()* , and *Io.Write()* functions enable a driver to access PCI controller registers in PCI I/O space.

The I/O operations are carried out exactly as requested. The caller is responsible for any alignment and I/O width issues which the bus, device, platform, or type of I/O might require. For example on some platforms, width requests of *EfiPciIoWidthUint64* do not work.

If *Width* is *EfiPciIoWidthUint8* , *EfiPciIoWidthUint16* , *EfiPciIoWidthUint32* , or *EfiPciIoWidthUint64* , then both *Address* and *Buffer* are incremented for each of the *Count* operations performed.

If *Width* is *EfiPciIoWidthFifoUint8* , *EfiPciIoWidthFifoUint16* , *EfiPciIoWidthFifoUint32* , or *EfiPciIoWidthFifoUint64* , then only *Buffer* is incremented for each of the *Count* operations performed. The read or write operation is performed *Count* times on the same *Address*.

If *Width* is *EfiPciIoWidthFillUint8* , *EfiPciIoWidthFillUint16* , *EfiPciIoWidthFillUint32* , or *EfiPciIoWidthFillUint64* , then only *Address* is incremented for each of the *Count* operations performed. The read or write operation is performed *Count* times from the first element of *Buffer*.

All the PCI transactions generated by this function are guaranteed to be completed before this function returns.

Status Codes Returned

EFI_SUCCESS	The data was read from or written to the PCI controller.
EFI_INVALID_PARAMETER	Width is invalid.
EFI_INVALID_PARAMETER	Buffer is *NULL*.
EFI_UNSUPPORTED	BarIndex not valid for this PCI controller.
EFI_UNSUPPORTED	The address range specified by Offset, Width, and Count is not valid for the PCI BAR specified by BarIndex.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.

14.4.8 EFI_PCI_IO_PROTOCOL.Pci.Read()

14.4.9 EFI_PCI_IO_PROTOCOL.Pci.Write()

Summary

Enable a PCI driver to access PCI controller registers in PCI configuration space.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_IO_PROTOCOL_CONFIG) (
  IN EFI_PCI_IO_PROTOCOL                        *This,
  IN EFI_PCI_IO_PROTOCOL_WIDTH                  Width,
  IN UINT32                                     Offset,
  IN UINTN                                      Count,
  IN OUT VOID                                   *Buffer
);
```

Parameters

This

A pointer to the See *EFI PCI I/O Protocol* instance. Type EFI_PCI_IO_PROTOCOL is defined in See *EFI PCI I/O Protocol*.

Width

Signifies the width of the memory operations. Type EFI_PCI_IO_PROTOCOL_WIDTH, defined in *EFI PCI I/O Protocol* .

Offset

The offset within the PCI configuration space for the PCI controller.

Count

The number of PCI configuration operations to perform. Bytes moved is Width size * Count, starting at Offset.

Buffer

For read operations, the destination buffer to store the results. For write operations, the source buffer to write data from.

Description

The *Pci.Read()* and *Pci.Write()* functions enable a driver to access PCI configuration registers for the PCI controller.

The PCI Configuration operations are carried out exactly as requested. The caller is responsible for any alignment and I/O width issues which the bus, device, platform, or type of I/O might require. For example on some platforms, width requests of *EfiPciIoWidthUint64* do not work.

If *Width* is *EfiPciIoWidthUint8* , *EfiPciIoWidthUint16* , *EfiPciIoWidthUint32* , or *EfiPciIoWidthUint64* , then both *Address* and *Buffer* are incremented for each of the *Count* operations performed.

If *Width* is *EfiPciIoWidthFifoUint8* , *EfiPciIoWidthFifoUint16* , *EfiPciIoWidthFifoUint32* , or *EfiPciIoWidthFifoUint64* , then only *Buffer* is incremented for each of the *Count* operations performed. The read or write operation is performed *Count* times on the same *Address*.

If *Width* is *EfiPciIoWidthFillUint8* , *EfiPciIoWidthFillUint16* , *EfiPciIoWidthFillUint32* , or *EfiPciIoWidthFillUint64* , then only *Address* is incremented for each of the *Count* operations performed. The read or write operation is performed *Count* times from the first element of *Buffer*.

All the PCI transactions generated by this function are guaranteed to be completed before this function returns.

Status Codes Returned

EFI_SUCCESS	The data was read from or written to the PCI controller.
EFI_INVALID_PARAMETER	Width is invalid.
EFI_INVALID_PARAMETER	Buffer is *NULL*.
EFI_UNSUPPORTED	The address range specified by Offset, Width, and Count is not valid for the PCI configuration header of the PCI controller.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.

14.4.10 EFI_PCI_IO_PROTOCOL.CopyMem()

Summary

Enables a PCI driver to copy one region of PCI memory space to another region of PCI memory space.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_IO_PROTOCOL_COPY_MEM) (
  IN EFI_PCI_IO_PROTOCOL                     *This,
  IN EFI_PCI_IO_PROTOCOL_WIDTH               Width,
  IN UINT8                                   DestBarIndex,
  IN UINT64                                  DestOffset,
  IN UINT8                                   SrcBarIndex,
  IN UINT64                                  SrcOffset,
  IN UINTN                                   Count
  );
```

Parameters

This

A pointer to the *EFI_PCI_IO_PROTOCOL* instance. Type EFI_PCI_IO_PROTOCOL is defined in *EFI_PCI_IO_Protocol* .

Width

Signifies the width of the memory operations. Type EFI_PCI_IO_PROTOCOL_WIDTH, defined in *EFI PCI I/O Protocol* .

DestBarIndex

The BAR index of the standard PCI Configuration header to use as the base address for the memory operation to perform. This allows all drivers to use BAR relative addressing. The legal range for this field is 0..5. However, the value **EFI_PCI_IO_PASS_THROUGH_BAR** can be used to bypass the BAR relative addressing and pass *Offset* to the PCI Root Bridge I/O Protocol unchanged. Type EFI_PCI_IO_PASS_THROUGH_BAR is defined in *EFI_PCI_IO_Protocol* .

DestOffset

The destination offset within the BAR specified by DestBarIndex to start the memory writes for the copy operation. The caller is responsible for aligning the DestOffset if required.

SrcBarIndex

The BAR index of the standard PCI Configuration header to use as the base address for the memory operation to perform. This allows all drivers to use BAR relative addressing. The legal range for this field is 0..5. However, the value **EFI_PCI_IO_PASS_THROUGH_BAR** can be used to bypass the BAR relative addressing and pass

Offset to the PCI Root Bridge I/O Protocol unchanged. Type EFI_PCI_IO_PASS_THROUGH_BAR is defined in *EFI_PCI_IO_Protocol* .

SrcOffset
The source offset within the BAR specified by SrcBarIndex to start the memory reads for the copy operation. The caller is responsible for aligning the SrcOffset if required.

Count
The number of memory operations to perform. Bytes moved is Width size * Count, starting at DestOffset and SrcOffset.

Description

The *CopyMem()* function enables a PCI driver to copy one region of PCI memory space to another region of PCI memory space on a PCI controller. This is especially useful for video scroll operations on a memory mapped video buffer.

The memory operations are carried out exactly as requested. The caller is responsible for satisfying any alignment and memory width restrictions that a PCI controller on a platform might require. For example on some platforms, width requests of *EfiPciIoWidthUint64* do not work.

If *Width* is *EfiPciIoWidthUint8* , *EfiPciIoWidthUint16* , *EfiPciIoWidthUint32* , or *EfiPciIoWidthUint64* , then *Count* read/write transactions are performed to move the contents of the *SrcOffset* buffer to the *DestOffset* buffer. The implementation must be reentrant, and it must handle overlapping *SrcOffset* and *DestOffset* buffers. This means that the implementation of *CopyMem()* must choose the correct direction of the copy operation based on the type of overlap that exists between the *SrcOffset* and *DestOffset* buffers. If either the *SrcOffset* buffer or the *DestOffset* buffer crosses the top of the processor's address space, then the result of the copy operation is unpredictable.

The contents of the *DestOffset* buffer on exit from this service must match the contents of the *SrcOffset* buffer on entry to this service. Due to potential overlaps, the contents of the *SrcOffset* buffer may be modified by this service. The following rules can be used to guarantee the correct behavior:

- If *DestOffset* > *SrcOffset* and *DestOffset* < (*SrcOffset* + *Width* size * *Count*), then the data should be copied from the *SrcOffset* buffer to the *DestOffset* buffer starting from the end of buffers and working toward the beginning of the buffers.
- Otherwise, the data should be copied from the *SrcOffset* buffer to the *DestOffset* buffer starting from the beginning of the buffers and working toward the end of the buffers.

All the PCI transactions generated by this function are guaranteed to be completed before this function returns. All the PCI write transactions generated by this function will follow the write ordering and completion rules defined in the PCI Specification. However, if the memory-mapped I/O region being accessed by this function has the *EFI_PCI_IO_ATTRIBUTE_MEMORY_CACHED* attribute set, then the transactions will follow the ordering rules defined by the processor architecture.

Status Codes Returned

EFI_SUCCESS	The data was copied from one memory region to another memory region.
EFI_INVALID_PARAMETER	Width is invalid.
EFI_UNSUPPORTED	DestBarIndex not valid for this PCI controller.
EFI_UNSUPPORTED	SrcBarIndex not valid for this PCI controller.
EFI_UNSUPPORTED	The address range specified by DestOffset, Width, and Count is not valid for the PCI BAR specified by DestBarIndex.
EFI_UNSUPPORTED	The address range specified by SrcOffset, Width, and Count is not valid for the PCI BAR specified by SrcBarIndex.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.

14.4.11 EFI_PCI_IO_PROTOCOL.Map()

Summary

Provides the PCI controller-specific addresses needed to access system memory.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_IO_PROTOCOL_MAP) (
  IN EFI_PCI_IO_PROTOCOL                    *This,
  IN EFI_PCI_IO_PROTOCOL_OPERATION          Operation,
  IN VOID                                   *HostAddress,
  IN OUT UINTN                              *NumberOfBytes,
  OUT EFI_PHYSICAL_ADDRESS                  *DeviceAddress,
  OUT VOID                                  **Mapping
  );
```

Parameters

This

A pointer to the *EFI_PCI_ROOT_BRIDGE_IO_PROTOCOL* instance. Type EFI_PCI_IO_PROTOCOL is defined in See *EFI PCI I/O Protocol*.

Operation

Indicates if the bus master is going to read or write to system memory. Type *EFI_PCI_IO_PROTOCOL_OPERATION* is defined in See *EFI PCI I/O Protocol*.

HostAddress

The system memory address to map to the PCI controller.

NumberOfBytes

On input the number of bytes to map. On output the number of bytes that were mapped.

DeviceAddress

The resulting map address for the bus master PCI controller to use to access the hosts HostAddress. Type EFI_PHYSICAL_ADDRESS is defined in *EFI_BOOT_SERVICES.AllocatePool()* . This address cannot be used by the processor to access the contents of the buffer specified by *HostAddress*.

Mapping

A resulting value to pass to *EFI-PCI-IO-PROTOCOL-Unmap()* .

Description

The *EFI_PCI_IO_PROTOCOL.Map()* function provides the PCI controller-specific addresses needed to access system memory. This function is used to map system memory for PCI bus master DMA accesses.

All PCI bus master accesses must be performed through their mapped addresses and such mappings must be freed with *EFI-PCI-IO-PROTOCOL-Unmap()* when complete. If the bus master access is a single read or write data transfer, then *EfiPciIoOperationBusMasterRead* or *EfiPciIoOperation-BusMasterWrite* is used and the range is unmapped to complete the operation. If performing an *EfiPciIoOperationBusMasterRead* operation, all the data must be present in system memory before the *Map()* is performed. Similarly, if performing an *EfiPciIoOperation-BusMasterWrite,* the data cannot be properly accessed in system memory until *Unmap()* is performed.

Bus master operations that require both read and write access or require multiple host device interactions within the same mapped region must use *EfiPciIoOperation-BusMasterCommonBuffer*. However, only memory allocated via the *EFI_PCI_IO_PROTOCOL.AllocateBuffer()* interface can be mapped for this operation type.

In all mapping requests the resulting *NumberOfBytes* actually mapped may be less than the requested amount. In this case, the DMA operation will have to be broken up into smaller chunks. The *Map()* function will map as much of the

DMA operation as it can at one time. The caller may have to loop on *Map()* and *Unmap()* in order to complete a large DMA transfer.

Status Codes Returned

EFI_SUCCESS	The range was mapped for the returned NumberOfBytes.
EFI_INVALID_PARAMETER	Operation is invalid.
EFI_INVALID_PARAMETER	*HostAddress* is *NULL*.
EFI_INVALID_PARAMETER	*NumberOfBytes* is *NULL*.
EFI_INVALID_PARAMETER	*DeviceAddress* is *NULL*.
EFI_INVALID_PARAMETER	*Mapping* is *NULL*.
EFI_UNSUPPORTED	The HostAddress cannot be mapped as a common buffer.
EFI_DEVICE_ERROR	The system hardware could not map the requested address.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.

14.4.12 EFI-PCI-IO-PROTOCOL-Unmap()

Summary

Completes the *EFI_PCI_IO_PROTOCOL.Map()* operation and releases any corresponding resources.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_IO_PROTOCOL_UNMAP) (
  IN EFI_PCI_IO_PROTOCOL                        *This,
  IN VOID                                       *Mapping
  );
```

Parameters

This

A pointer to the *EFI_PCI_IO_PROTOCOL* instance. Type EFI_PCI_IO_PROTOCOL is defined in *EFI PCI I/O Protocol*.

Mapping

The mapping value returned from Map().

Description

The *Unmap()* function completes the *Map()* operation and releases any corresponding resources. If the operation was an *EfiPciIoOperationBusMasterWrite* , the data is committed to the target system memory. Any resources used for the mapping are freed.

Status Codes Returned

EFI_SUCCESS	The range was unmapped.
EFI_DEVICE_ERROR	The data was not committed to the target system memory.

14.4.13 EFI_PCI_IO_PROTOCOL.AllocateBuffer()

Summary

Allocates pages that are suitable for an *EfiPciIoOperationBusMasterCommonBuffer* mapping.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_IO_PROTOCOL_ALLOCATE_BUFFER) (
  IN EFI_PCI_IO_PROTOCOL                *This,
  IN EFI_ALLOCATE_TYPE                  Type,
  IN EFI_MEMORY_TYPE                    MemoryType,
  IN UINTN                              Pages,
  OUT VOID                              **HostAddress,
  IN UINT64                             Attributes
  );
```

Parameters

This

A pointer to the See *EFI PCI I/O Protocol* instance. Type EFI_PCI_IO_PROTOCOL is defined in *EFI PCI I/O Protocol*.

Type

This parameter is not used and must be ignored.

MemoryType

The type of memory to allocate, EfiBootServicesData or EfiRuntimeServicesData. Type EFI_MEMORY_TYPE is defined in *EFI_PCI_IO_PROTOCOL.AllocateBuffer()* .

Pages

The number of pages to allocate.

HostAddress

A pointer to store the base system memory address of the allocated range.

Attributes

The requested bit mask of attributes for the allocated range. Only the attributes EFI_PCI_IO_ATTRIBUTE_MEMORY_WRITE_COMBINE, and EFI_PCI_IO_ATTRIBUTE_MEMORY_CACHED may be used with this function. If any other bits are set, then EFI_UNSUPPORTED is returned. This function may choose to ignore this bit mask. The EFI_PCI_IO_ATTRIBUTE_MEMORY_WRITE_COMBINE, and EFI_PCI_IO_ATTRIBUTE_MEMORY_CACHED attributes provide a hint to the implementation that may improve the performance of the calling driver. The implementation may choose any default for the memory attributes including write combining, cached, both, or neither as long as the allocated buffer can be seen equally by both the processor and the PCI bus master.

Description

The *AllocateBuffer()* function allocates pages that are suitable for an *EfiPciIoOperationBusMasterCommonBuffer* mapping. This means that the buffer allocated by this function must support simultaneous access by both the processor and a PCI Bus Master. The device address that the PCI Bus Master uses to access the buffer can be retrieved with a call to *EFI_PCI_IO_PROTOCOL.Map()*.

If the current attributes of the PCI controller has the *EFI_PCI_IO_ATTRIBUTE_DUAL_ADDRESS_CYCLE* bit set, then when the buffer allocated by this function is mapped with a call to *Map()* , the device address that is returned by *Map()* must be within the 64-bit device address space of the PCI Bus Master. The attributes for a PCI controller can be managed by calling *EFI_PCI_IO_PROTOCOL.Attributes()*.

If the current attributes for the PCI controller has the *EFI_PCI_IO_ATTRIBUTE_DUAL_ADDRESS_CYCLE* bit clear, then when the buffer allocated by this function is mapped with a call to *Map()* , the device address that is returned by *Map()* must be within the 32-bit device address space of the PCI Bus Master. The attributes for a PCI controller can be managed by calling *Attributes()*.

If the memory allocation specified by *MemoryType* and *Pages* cannot be satisfied, then *EFI_OUT_OF_RESOURCES* is returned.

Status Codes Returned

EFI_SUCCESS	The requested memory pages were allocated.
EFI_INVALID_PARAMETER	MemoryType is invalid.
EFI_INVALID_PARAMETER	*HostAddress* is *NULL*.
EFI_UNSUPPORTED	Attributes is unsupported. The only legal attribute bits are *MEMORY_WRITE_COMBINE* and *MEMORY_CACHED*.
EFI_OUT_OF_RESOURCES	The memory pages could not be allocated.

14.4.14 EFI_PCI_IO_PROTOCOL.FreeBuffer()

Summary

Frees memory that was allocated with *EFI_PCI_IO_PROTOCOL.AllocateBuffer()* .

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_IO_PROTOCOL_FREE_BUFFER) (
  IN EFI_PCI_IO_PROTOCOL                *This,
  IN UINTN                              Pages,
  IN VOID                               *HostAddress
  );
```

Parameters

This

A pointer to the *EFI_PCI_IO_PROTOCOL* instance. Type EFI_PCI_IO_PROTOCOL is defined in *EFI PCI I/O Protocol*.

Pages

The number of pages to free.

HostAddress

The base system memory address of the allocated range.

Description

The *FreeBuffer()* function frees memory that was allocated with *AllocateBuffer()*.

Status Codes Returned

EFI_SUCCESS	The requested memory pages were freed.
EFI_INVALID_PARAMETER	The memory range specified by HostAddress and Pages was not allocated with *AllocateBuffer()*.

14.4.15 EFI_PCI_IO_PROTOCOL.Flush()

Summary

Flushes all PCI posted write transactions from a PCI host bridge to system memory.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_IO_PROTOCOL_FLUSH) (
  IN EFI_PCI_IO_PROTOCOL              *This
  );
```

Parameters

This

A pointer to the *EFI_PCI_IO_PROTOCOL* instance. Type EFI_PCI_IO_PROTOCOL is defined in *EFI PCI I/O Protocol*.

Description

The *Flush()* function flushes any PCI posted write transactions from a PCI host bridge to system memory. Posted write transactions are generated by PCI bus masters when they perform write transactions to target addresses in system memory.

This function does not flush posted write transactions from any PCI bridges. A PCI controller specific action must be taken to guarantee that the posted write transactions have been flushed from the PCI controller and from all the PCI bridges into the PCI host bridge. This is typically done with a PCI read transaction from the PCI controller prior to calling *Flush()* .

If the PCI controller specific action required to flush the PCI posted write transactions has been performed, and this function returns *EFI_SUCCESS* , then the PCI bus master's view and the processor's view of system memory are guaranteed to be coherent. If the PCI posted write transactions cannot be flushed from the PCI host bridge, then the PCI bus master and processor are not guaranteed to have a coherent view of system memory, and *EFI_DEVICE_ERROR* is returned.

Status Codes Returned

EFI_SUCCESS	The PCI posted write transactions were flushed from the PCI host bridge to system memory.
EFI_DEVICE_ERROR	The PCI posted write transactions were not flushed from the PCI host bridge due to a hardware error.

14.4.16 EFI_PCI_IO_PROTOCOL.GetLocation()

Summary

Retrieves this PCI controller's current PCI bus number, device number, and function number.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_IO_PROTOCOL_GET_LOCATION) (
  IN EFI_PCI_IO_PROTOCOL              *This,
  OUT UINTN                           *SegmentNumber,
  OUT UINTN                           *BusNumber,
  OUT UINTN                           *DeviceNumber,
  OUT UINTN                           *FunctionNumber
  );
```

Parameters

This

A pointer to the *EFI_PCI_IO_PROTOCOL* instance. Type EFI_PCI_IO_PROTOCOL is defined in *EFI PCI I/O Protocol*.

SegmentNumber

The PCI controller's current PCI segment number.

BusNumber

The PCI controller's current PCI bus number.

DeviceNumber

The PCI controller's current PCI device number.

FunctionNumber

The PCI controller's current PCI function number.

Description

The *GetLocation()* function retrieves a PCI controller's current location on a PCI Host Bridge. This is specified by a PCI segment number, PCI bus number, PCI device number, and PCI function number. These values can be used with the PCI Root Bridge I/O Protocol to perform PCI configuration cycles on the PCI controller, or any of its peer PCI controller's on the same PCI Host Bridge.

Status Codes Returned

EFI_SUCCESS	The PCI controller location was returned.
EFI_INVALID_PARAMETER	SegmentNumber is **NULL**.
EFI_INVALID_PARAMETER	BusNumber is **NULL**.
EFI_INVALID_PARAMETER	DeviceNumber is **NULL**.
EFI_INVALID_PARAMETER	FunctionNumber is **NULL**.

14.4.17 EFI_PCI_IO_PROTOCOL.Attributes()

Summary

Performs an operation on the attributes that this PCI controller supports. The operations include getting the set of supported attributes, retrieving the current attributes, setting the current attributes, enabling attributes, and disabling attributes.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_IO_PROTOCOL_ATTRIBUTES) (
  IN EFI_PCI_IO_PROTOCOL                      *This,
  IN EFI_PCI_IO_PROTOCOL_ATTRIBUTE_OPERATION   Operation,
  IN UINT64                                    Attributes,
  OUT UINT64                                  *Result OPTIONAL
  );
```

Parameters

This

A pointer to the *EFI_PCI_IO_PROTOCOL* instance. Type EFI_PCI_IO_PROTOCOL is defined in *EFI PCI I/O Protocol*.

Operation

The operation to perform on the attributes for this PCI controller. Type EFI_PCI_IO_PROTOCOL_ATTRIBUTE_OPERATION is defined in "Related Definitions" below.

Attributes

The mask of attributes that are used for Set, Enable, and Disable operations. The available attributes are listed in See *EFI PCI I/O Protocol*.

Result

A pointer to the result mask of attributes that are returned for the Get and Supported operations. This is an optional parameter that may be NULL for the Set, Enable, and Disable operations. The available attributes are listed in *EFI PCI I/O Protocol*.

Related Definitions

```
//*******************************************************
// EFI_PCI_IO_PROTOCOL_ATTRIBUTE_OPERATION
//*******************************************************
typedef enum {
  EfiPciIoAttributeOperationGet,
  EfiPciIoAttributeOperationSet,
  EfiPciIoAttributeOperationEnable,
  EfiPciIoAttributeOperationDisable,
  EfiPciIoAttributeOperationSupported,
  EfiPciIoAttributeOperationMaximum
}  EFI_PCI_IO_PROTOCOL_ATTRIBUTE_OPERATION;
```

EfiPciIoAttributeOperationGet

Retrieve the PCI controller's current attributes, and return them in Result. If Result is NULL, then EFI_INVALID_PARAMER is returned. For this operation, Attributes is ignored.

EfiPciIoAttributeOperationSet
Set the PCI controller's current attributes to Attributes. If a bit is set in Attributes that is not supported by this PCI controller or one of its parent bridges, then EFI_UNSUPPORTED is returned. For this operation, Result is an optional parameter that may be NULL.

EfiPciIoAttributeOperationEnable
Enable the attributes specified by the bits that are set in Attributes for this PCI controller. Bits in Attributes that are clear are ignored. If a bit is set in Attributes that is not supported by this PCI controller or one of its parent bridges, then EFI_UNSUPPORTED is returned. For this operation, Result is an optional parameter that may be NULL.

EfiPciIoAttributeOperationDisable
Disable the attributes specified by the bits that are set in Attributes for this PCI controller. Bits in Attributes that are clear are ignored. If a bit is set in Attributes that is not supported by this PCI controller or one of its parent bridges, then EFI_UNSUPPORTED is returned. For this operation, Result is an optional parameter that may be NULL.

EfiPciIoAttributeOperationSupported
Retrieve the PCI controller's supported attributes, and return them in Result. If Result is NULL, then EFI_INVALID_PARAMER is returned. For this operation, Attributes is ignored.

Description

The *Attributes()* function performs an operation on the attributes associated with this PCI controller. If *Operation* is greater than or equal to the maximum operation value, then *EFI_INVALID_PARAMETER* is returned. If *Operation* is *Get* or *Supported* , and *Result* is *NULL* , then *EFI_INVALID_PARAMETER* is returned. If *Operation* is *Set* , *Enable* , or *Disable* for an attribute that is not supported by the PCI controller, then *EFI_UNSUPPORTED* is returned. Otherwise, the operation is performed as described in "Related Definitions" and *EFI_SUCCESS* is returned. It is possible for this function to return *EFI_UNSUPPORTED* even if the PCI controller supports the attribute. This can occur when the PCI root bridge does not support the attribute. For example, if VGA I/O and VGA Memory transactions cannot be forwarded onto PCI root bridge #2, then a request by a PCI VGA driver to enable the *VGA_IO* and *VGA_MEMORY* bits will fail even though a PCI VGA controller behind PCI root bridge #2 is able to decode these transactions.

This function will also return *EFI_UNSUPPORTED* if more than one PCI controller on the same PCI root bridge has already successfully requested one of the ISA addressing attributes. For example, if one PCI VGA controller had already requested the *VGA_IO* and *VGA_MEMORY* attributes, then a second PCI VGA controller on the same root bridge cannot succeed in requesting those same attributes. This restriction applies to the ISA-, VGA-, and IDE-related attributes.

Status Codes Returned

EFI_SUCCESS	The operation on the PCI controller's attributes was completed. If the operation was *Get* or *Supported* , then the attribute mask is returned in Result.
EFI_INVALID_PARAMETER	Operation is greater than or equal to *EfiPciIoAttributeOperationMaximum*.
EFI_INVALID_PARAMETER	Operation is *Get* and Result is **NULL**.
EFI_INVALID_PARAMETER	Operation is *Supported* and Result is **NULL**.
EFI_UNSUPPORTED	Operation is *Set* , and one or more of the bits set in Attributes are not supported by this PCI controller or one of its parent bridges.
EFI_UNSUPPORTED	Operation is *Enable* , and one or more of the bits set in Attributes are not supported by this PCI controller or one of its parent bridges.
EFI_UNSUPPORTED	Operation is *Disable* , and one or more of the bits set in Attributes are not supported by this PCI controller or one of its parent bridges.

14.4.18 EFI_PCI_IO_PROTOCOL.GetBarAttributes()

Summary

Gets the attributes that this PCI controller supports setting on a BAR using *EFI_PCI_IO_PROTOCOL.SetBarAttributes()* , and retrieves the list of resource descriptors for a BAR.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_IO_PROTOCOL_GET_BAR_ATTRIBUTES) (
  IN EFI_PCI_IO_PROTOCOL                *This,
  IN UINT8                              BarIndex,
  OUT UINT64                            *Supports OPTIONAL,
  OUT VOID                              **Resources OPTIONAL
  );
```

Parameters

This
A pointer to the *EFI_PCI_IO_PROTOCOL* instance. Type EFI_PCI_IO_PROTOCOL is defined in *EFI PCI I/O Protocol*.

BarIndex
The BAR index of the standard PCI Configuration header to use as the base address for resource range. The legal range for this field is 0..5.

Supports
A pointer to the mask of attributes that this PCI controller supports setting for this BAR with SetBarAttributes(). The list of attributes is listed in See *EFI PCI I/O Protocol*. This is an optional parameter that may be NULL.

Resources
A pointer to the resource descriptors that describe the current configuration of this BAR of the PCI controller. This buffer is allocated for the caller with the Boot Service *EFI_BOOT_SERVICES.AllocatePool()* . It is the caller's responsibility to free the buffer with the Boot Service *EFI_BOOT_SERVICES.FreePool()* . See "Related Definitions" below for the resource descriptors that may be used. This is an optional parameter that may be **NULL**.

Related Definitions

There are only two resource descriptor types from the ACPI Specification that may be used to describe the current resources allocated to BAR of a PCI Controller. These are the QWORD Address Space Descriptor, and the End Tag. The QWORD Address Space Descriptor can describe memory, I/O, and bus number ranges for dynamic or fixed resources. The configuration of a BAR of a PCI Controller is described with one or more QWORD Address Space Descriptors followed by an End Tag. The Tables below contain these two descriptor types. Please see the ACPI Specification for details on the field values. The ACPI Specification does not define how to the use the Address Translation Offset for non-bridge devices. The UEFI Specification is extending the definition of Address Translation Offset to support systems that have different mapping for HostAddress and DeviceAddress. The definition of the Address Space Granularity field in the QWORD Address Space Descriptor differs from the ACPI Specification and the definition in the table below is the one that must be used.

Table 14.37: QWORD Address Space Descriptor

Byte Offset	Byte Length	Data	Description
0x00	0x01	0x8A	QWORD Address Space Descriptor
0x01	0x02	0x2B	Length of this descriptor in bytes not including the first two fields
0x03	0x01		Resource Type 0 - Memory Range 1 - I/O Range 2 - Bus Number Range
0x04	0x01		General Flags
0x05	0x01		Type Specific Flags
0x06	0x08		Address Space Granularity. Used to differentiate between a 32-bit memory request and a 64-bit memory request. For a 32-bit memory request, this field should be set to 32. For a 64-bit memory request, this field should be set to 64.
0x0E	0x08		Address Range Minimum. Starting address of BAR.
0x16	0x08		Address Range Maximum. Ending address of BAR.
0x1E	0x08		Address Translation Offset. Offset to apply to the Starting address of a BAR to convert it to a PCI address. This value is zero unless the HostAddress and DeviceAddress for the BAR are different.
0x26	0x08		Address Length

Table 14.38: End Tag

Byte Offset	Byte Length	Data	Description
0x00	0x01	0x79	End Tag
0x01	0x01	0x00	Checksum. If 0, then checksum is assumed to be valid.

Description

The *GetBarAttributes()* function returns in *Supports* the mask of attributes that the PCI controller supports setting for the BAR specified by *BarIndex*. It also returns in *Resources* a list of resource descriptors for the BAR specified by *BarIndex*. Both *Supports* and *Resources* are optional parameters. If both *Supports* and *Resources* are **NULL** , then *EFI_INVALID_PARAMETER* is returned. It is the caller's responsibility to free *Resources* with the Boot Service *EFI_BOOT_SERVICES.FreePool()* when the caller is done with the contents of *Resources*. If there are not enough resources to allocate *Resources* , then *EFI_OUT_OF_RESOURCES* is returned.

If a bit is set in *Supports* , then the PCI controller supports this attribute type for the BAR specified by *BarIndex* , and a call can be made to *EFI_PCI_IO_PROTOCOL.SetBarAttributes()* using that attribute type.

Status Codes Returned

EFI_SUCCESS	If Supports is not *NULL* , then the attributes that the PCI controller supports are returned in Supports. If Resources is not *NULL* , then the resource descriptors that the PCI controller is currently using are returned in Resources.
EFI_OUT_OF_RESOURCES	There are not enough resources available to allocate Resources.
EFI_UNSUPPORTED	BarIndex not valid for this PCI controller.
EFI_INVALID_PARAMETER	Both Supports and Attributes are *NULL*.

14.4.19 EFI_PCI_IO_PROTOCOL.SetBarAttributes()

Summary

Sets the attributes for a range of a BAR on a PCI controller.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_PCI_IO_PROTOCOL_SET_BAR_ATTRIBUTES) (
  IN EFI_PCI_IO_PROTOCOL           *This,
  IN UINT64                        Attributes,
  IN UINT8                         BarIndex,
  IN OUT UINT64                    *Offset,
  IN OUT UINT64                    *Length
);
```

Parameters

This
A pointer to the *EFI PCI I/O Protocol* instance. Type EFI_PCI_IO_PROTOCOL is defined in *EFI PCI I/O Protocol*.

Attributes
The mask of attributes to set for the resource range specified by BarIndex, Offset, and Length.

BarIndex
The BAR index of the standard PCI Configuration header to use as the base address for the resource range. The legal range for this field is 0..5.

Offset
A pointer to the BAR relative base address of the resource range to be modified by the attributes specified by Attributes. On return, *Offset* will be set to the actual base address of the resource range. Not all resources can be set to a byte boundary, so the actual base address may differ from the one passed in by the caller.

Length
A pointer to the length of the resource range to be modified by the attributes specified by Attributes. On return, *Length* will be set to the actual length of the resource range. Not all resources can be set to a byte boundary, so the actual length may differ from the one passed in by the caller.

Description

The *SetBarAttributes()* function sets the attributes specified in *Attributes* for the PCI controller on the resource range specified by *BarIndex* , *Offset* , and *Length*. Since the granularity of setting these attributes may vary from resource type to resource type, and from platform to platform, the actual resource range and the one passed in by the caller may differ. As a result, this function may set the attributes specified by *Attributes* on a larger resource range than the caller requested. The actual range is returned in *Offset* and *Length*. The caller is responsible for verifying that the actual range for which the attributes were set is acceptable.

If the attributes are set on the PCI controller, then the actual resource range is returned in *Offset* and *Length* , and *EFI_SUCCESS* is returned. Many of the attribute types also require that the state of the PCI Host Bus Controller and the state of any PCI to PCI bridges between the PCI Host Bus Controller and the PCI Controller to be modified. This function will only return *EFI_SUCCESS* is all of these state changes are made. The PCI Controller may support a combination of attributes, but unless the PCI Host Bus Controller and the PCI to PCI bridges also support that same combination of attributes, then this call will return an error.

If the attributes specified by *Attributes* , or the resource range specified by *BarIndex* , *Offset* , and *Length* are not supported by the PCI controller, then *EFI_UNSUPPORTED* is returned. The set of supported attributes for the PCI controller can be found by calling *EFI_PCI_IO_PROTOCOL.GetBarAttributes()* .

If either *Offset* or *Length* is *NULL* then *EFI_INVALID_PARAMETER* is returned.

If there are not enough resources available to set the attributes, then *EFI_OUT_OF_RESOURCES* is returned.

Status Codes Returned

EFI_SUCCESS	The set of attributes specified by Attributes for the resource range specified by BarIndex, Offset, and Length were set on the PCI controller, and the actual resource range is returned in Offset and Length.
EFI_UNSUPPORTED	The set of attributes specified by Attributes is not supported by the PCI controller for the resource range specified by BarIndex, Offset, and Length.
EFI_INVALID_PARAMETER	Offset is *NULL*.
EFI_INVALID_PARAMETER	Length is *NULL*.
EFI_OUT_OF_RESOURCES	There are not enough resources to set the attributes on the resource range specified by BarIndex, Offset, and Length.

14.4.20 PCI Device Paths

An *EFI_PCI_IO_PROTOCOL* must be installed on a handle for its services to be available to PCI device drivers. In addition to the *EFI_PCI_IO_PROTOCOL* , an *EFI Device Path Protocol* must also be installed on the same handle (see chapter 9).

Typically, an ACPI Device Path Node is used to describe a PCI Root Bridge. Depending on the bus hierarchy in the system, additional device path nodes may precede this ACPI Device Path Node. A PCI device path is described with PCI Device Path Nodes. There will be one PCI Device Path node for the PCI controller itself, and one PCI Device Path Node for each PCI to PCI Bridge that is between the PCI controller and the PCI Root Bridge.

Table *PCI Device 7, Function 0 on PCI Root Bridge 0* shows an example device path for a PCI controller that is located at PCI device number 0x07 and PCI function 0x00, and is directly attached to a PCI root bridge. This device path consists of an ACPI Device Path Node, a PCI Device Path Node, and a Device Path End Structure. The _HID and _UID must match the ACPI table description of the PCI Root Bridge. The shorthand notation for this device path is:

```
ACPI(PNP0A03,0)/PCI(7,0)
```

Table 14.41: PCI Device 7, Function 0 on PCI Root Bridge 0

Byte Offset	Byte Length	Data	Description
0x00	0x01	0x02	Generic Device Path Header - Type ACPI Device Path
0x01	0x01	0x01	Sub type - ACPI Device Path
0x02	0x02	0x0C	Length - 0x0C bytes
0x04	0x04	0x41D0, 0x0A03	_HID PNP0A03 - 0x41D0 represents the compressed string ‘PNP’ and is encoded in the low order bytes. The compression method is described in the ACPI Specification.
0x08	0x04	0x0000	_UID
0x0C	0x01	0x01	Generic Device Path Header - Type Hardware Device Path
0x0D	0x01	0x01	Sub type - PCI
0x0E	0x02	0x06	Length - 0x06 bytes
0x10	0x01	0x00	PCI Function
0x11	0x01	0x07	PCI Device

0x16	0x01	0x00	PCI Function
0x17	0x01	0x07	PCI Device
0x18	0x01	0x7F	Generic Device Path Header - Type End of Hardware Device Path
0x19	0x01	0xFF	Sub type - End of Entire Device Path
0x1A	0x02	0x04	Length - 0x04 bytes

14.4.21 PCI Option ROMs

EFI takes advantage of both the PCI Firmware Specification and the PE/COFF Specification to store EFI images in a PCI Option ROM. There are several rules that must be followed when constructing a PCI Option ROM:

- A PCI Option ROM can be no larger than 16 MiB.
- A PCI Option ROM may contain one or more images.
- Each image must being on a 512-byte boundary.
- Each image must be an even multiple of 512 bytes in length. This means that images that are not an even multiple of 512 bytes in length must be padded to the next 512-byte boundary.
- Legacy Option ROM images begin with a Standard PCI Expansion ROM Header (*Standard PCI Expansion ROM Header (Example from PCI Firmware Specification 3.0)* (example-from-pci-firmware-specification-3.0) .

- EFI Option ROM images begin with an EFI PCI Expansion ROM Header (*Recommended PCI Device Driver Layout*).
- Each image must contain a PCIR data structure in the first 64 KiB of the image.
- The image data for an EFI Option ROM image must begin in the first 64 KiB of the image.
- The image data for an EFI Option ROM image must be a PE/COFF image or a compressed PE/COFF image following the UEFI Compression Algorithm, and referencing *Appendix H — Compression Source Code* for the Compression Source Code.
- The PCIR data structure must begin on a 4-byte boundary.
- If the PCI Option ROM contains a Legacy Option ROM image, it must be the first image.
- The images are placed in the PCI Option ROM in order from highest to lowest priority. This priority is used to build the ordered list of Driver Image Handles that are produced by the Bus Specific Driver Override Protocol for a PCI Controller.
- xxxx When PCI device provides an EFI option ROM that is signed in accordance with Chapter 27, use of UEFI Compression Algorithm storage option is preferred. When performing signature validation upon compressed driver, the size returned by *EFI_DECOMPRESS_PROTOCOL.GetInfo()* will be used as driver size and input to signature validation process. Thus any post-driver padding required to reach exact multiple of 512 bytes per *Unsigned PCI Driver Image Layout* is ignored by signature validation.
- When PCI device provides an EFI option ROM that is signed in accordance with Chapter 27 and stored uncompressed, the end of the driver for signature validation will be the assumed to be the 512-byte boundary indicated by the 'Initialization Size' value in the EFI PCI Expansion ROM Header (Table *EFI PCI Expansion ROM Header*). As the signed driver may not exactly fill the indicated 'Initialization Size', it is recommended that the value 'Offset to EFI Image' (also Table *EFI PCI Expansion ROM Header*) be adjusted to ensure the last byte of the signed, uncompressed driver, coincides with the end of the ROM as indicated by 'Initialization Size'. And any required padding bytes are to be inserted ahead of the signed uncompressed driver image.

There are several options available when building a PCI option ROM for a PCI adapter. A PCI Option ROM can choose to support only a legacy PC-AT platform, only an EFI compliant platform, or both. This flexibility allows a migration path from adapters that support only legacy PC-AT platforms, to adapters that support both PC-AT platforms and EFI compliant platforms, to adapters that support only EFI compliant platforms. The following is a list of the image combinations that may be placed in a PCI option ROM. This is not an exhaustive list. Instead, it provides what will likely be the most common PCI option ROM layouts. EFI complaint system firmware must work with all of these PCI option ROM layouts, plus any other layouts that are possible within the PCI Firmware Specification. The format of a Legacy Option ROM image is defined in the PCI Firmware Specification.

- Legacy Option ROM image
- IA-32 UEFI driver
- x64 UEFI driver
- AArch32 UEFI driver
- AArch64 UEFI driver
- RISCV32 UEFI driver
- RISCV64 UEFI driver
- RISCV128 UEFI driver
- Legacy Option ROM image + x64 UEFI driver
- Legacy Option ROM image + x64 UEFI driver + AArch64 UEFI driver
- x64 UEFI driver + AArch64 UEFI driver

- Itanium Processor Family UEFI driver
- EBC Driver

In addition to combinations of UEFI drivers with different processor binding, it is also possible to include multiple drivers of different function but the same processor binding. When processing option ROM contents, all drivers of appropriate processor binding type must be loaded and added to ordered list of drivers previously mentioned.

It is also possible to place a application written to this specification in a PCI Option ROM. However, the PCI Bus Driver will ignore these images. The exact mechanism by which applications can be loaded and executed from a PCI Option ROM is outside the scope of this document.

Table 14.43: Standard PCI Expansion ROM Header (Example from PCI Firmware Specification 3.0)

Offset	Byte Length	Value	Description
0x00	1	0x55	ROM Signature, byte 1
0x01	1	0xAA	ROM Signature, byte 2
0x02-0x17	22	XX	Reserved per processor architecture unique data
0x18-0x19	2	XX	Pointer to PCIR Data Structure

Table 14.44: PCI Expansion ROM Code Types (Example from PCI Firmware Specification 3.0)

Code Type	**Description**
0x00	IA-32, PC-AT compatible
0x01	Open Firmware standard for PCI
0x02	Hewlett-Packard PA RISC
0x03	EFI Image
0x04-0xFF	Reserved

Table 14.45: EFI PCI Expansion ROM Header

Offset	Byte Length	Value	Description
0x00	1	0x55	ROM Signature, byte 1
0x01	1	0xAA	ROM Signature, byte 2
0x02	2	XXXX	Initialization Size - size of this image in units of 512 bytes. The size includes this header.
0x04	4	0x0EF1	Signature from EFI image header
0x08	2	XX	Subsystem value for EFI image header
0x0a	2	XX	Machine type from EFI image header
0x0c	2	XX	Compression type 0x0000 - The image is uncompressed 0x0001 - The image is compressed. See the UEFI Compression Algorithm and *Appendix H — Compression Source Code*. 0x0002 - 0xFFFF - Reserved
0x0e	8	0x00	Reserved

0x18	2	XX	Offset to PCIR Data Structure

14.4.22 PCI Bus Driver Responsibilities

A PCI Bus Driver must scan a PCI Option ROM for PCI Device Drivers. If a PCI Option ROM is found during PCI Enumeration, then a copy of the PCI Option ROM is placed in a memory buffer. The PCI Bus Driver will use the memory copy of the PCI Option ROM to search for UEFI drivers after PCI Enumeration. The PCI Bus Driver will search the list of images in a PCI Option ROM for the ones that have a Code Type of 0x03 in the PCIR Data Structure, and a Signature of 0xEF1 in the EFI PCI Expansion ROM Header. Then, it will examine the Subsystem Type of the EFI PCI Expansion ROM Header. If the Subsystem Type is *IMAGE_SUBSYSTEM_EFI_BOOT_SERVICE_DRIVER* (11) or *IMAGE_SUBSYSTEM_EFI_RUNTIME_DRIVER* (12), then the PCI Bus Driver can load the PCI Device Driver from the PCI Option ROM. The Offset to EFI Image Header field of the EFI PCI Expansion ROM Header is used to get a pointer to the beginning of the PE/COFF image in the PCI Option ROM. The PE/COFF image may have been compressed using the UEFI Compression Algorithm. If it has been compressed, then the PCI Bus Driver must decompress the driver to a memory buffer. The Boot Service *EFI_BOOT_SERVICES.LoadImage()* can then be used to load the driver. All UEFI driver images discovered in the PCI Option ROM and meeting these requirements must be processed and loaded via *LoadImage()* . If the platform does not support the Machine Type of the driver, then *LoadImage()* may fail.

It is the PCI Bus Driver's responsibility to verify that the Expansion ROM Header and PCIR Data Structure are valid. It is the responsibly of the Boot Service *LoadImage()* to verify that the PE/COFF image is valid. The Boot Service *LoadImage()* may fail for several reasons including a corrupt PE/COFF image or an unsupported Machine Type.

If a PCI Option ROM contains one or more UEFI images, then the PCI Bus Driver must install an instance of the *EFI_LOAD_FILE2_PROTOCOL* on the PCI controller handle. Then, when the PCI Bus Driver loads a PE/COFF image from a PCI Option ROM using the Boot Service *LoadImage()* , the PCI Bus Driver must provide the device path of the image being loaded. The device path of an image loaded from a PCI Option ROM must be the device path to the PCI Controller to which the PCI Option ROM is attached followed by a Relative Offset Range node. The Starting Offset field of the Relative Offset Range node must be the byte offset from the beginning of the PCI Option ROM to the beginning of the EFI Option ROM image, and the Ending Offset field of the Relative Offset Range node must be the byte offset from the beginning of the PCI Option ROM to the end of the EFI Option ROM image. The table below shows an example device path for an EFI driver loaded from a PCI Option ROM. The EFI Driver starts at offset 0x8000 into the PCI Option ROM and is 0x2000 bytes long. The shorthand notation for this device path is:

```
PciRoot(0)/PCI(5,0)/PCI(7,0)/ Offset(0x8000,0x9FFF)
```

Table 14.46: Device Path for an EFI Driver loaded from PCIO ption ROM

Byte Offset	Byte Length	Data	Description
0x00	0x01	0x02	Generic Device Path Header - Type ACPI Device Path
0x01	0x01	0x01	Sub type - ACPI Device Path
0x02	0x02	0x0C	Length - 0x0C bytes
0x04	0x04	0x41D0, 0x0A03	_HID PNP0A03 - 0x41D0 represents the compressed string 'PNP' and is encoded in the low order bytes. The compression method is described in the ACPI Specification.
0x08	0x04	0x0000	_UID
0x0C	0x01	0x01	Generic Device Path Header - Type Hardware Device Path
0x0D	0x01	0x01	Sub type - PCI
0x0E	0x02	0x06	Length - 0x06 bytes
0x10	0x01	0x00	PCI Function

continues on next page

Table 14.46 – continued from previous page

0x11	0x01	0x05	PCI Device
0x12	0x01	0x01	Generic Device Path Header - Type Hardware Device Path

0x14	0x02	0x06	Length - 0x06 bytes
0x16	0x01	0x00	PCI Function
0x17	0x01	0x07	PCI Device
0x18	0x01	0x04	Generic Device Path Header - Type Media Device Path
0x19	0x01	0x08	Sub type - Relative Offset Range
0x1A	0x02	0x14	Length - 0x14 bytes
0x1C	0x08	0x8000	Start Address - Offset into PCI Option ROM
0x24	0x08	0x9FFF	End Address - Offset into PCI Option ROM
0x2C	0x01	0x7F	Generic Device Path Header - Type End of Hardware Device Path
0x2D	0x01	0xFF	Sub type - End of Entire Device Path
0x2E	0x02	0x04	Length - 0x04 bytes

The PCI Option ROM search may produce one or more Driver Image Handles for the PCI Controller that is associated with the PCI Option ROM. The PCI Bus Driver is responsible for producing a Bus Specific Driver Override Protocol instance for every PCI Controller has a PCI Option ROM that contains one or more UEFI Drivers. The Bus Specific Driver Override Protocol produces an ordered list of Driver Image Handles. The order that the UEFI Drivers are placed in the PCI Option ROM is the order of Driver Image Handles that must be returned by the Bus Specific Driver Override Protocol. This gives the party that builds the PCI Option ROM control over the order that the drivers are used in the Boot Service *EFI_BOOT_SERVICES.ConnectController()*.

14.4.23 PCI Device Driver Responsibilities

A PCI Device Driver should not be designed to care where it is stored. It can reside in a PCI Option ROM, the system's motherboard ROM, a hard drive, a CD-ROM drive, etc. All PCI Device Drivers are compiled and linked to generate a PE/COFF image. When a PE/COFF image is placed in a PCI Option ROM, it must follow the rules outlined in See *PCI Option ROMs*. The recommended image layout is to insert an EFI PCI Expansion ROM Header and a PCIR Data Structure in front of the PE/COFF image, and pad the entire image up to the next 512-byte boundary. See *Unsigned PCI Driver Image Layout* shows the format of a single PCI Device Driver that can be added to a PCI Option ROM.

Following are recommended layouts and flow charts for various types of driver signage and compression states for PCI device driver images. See *Unsigned PCI Driver Image Layout* shows an unsigned layout.

Figures *Signed and Compressed PCI Driver Image Flow* and *Signed and Compressed PCI Driver Image Flow* show a signed and compressed PCI device driver image flow chart and layout, respectively.

Figure *Signed but not Compressed PCI Driver Image Flow* and Figure *Signed and Uncompressed PCI Driver Image Layout* show a signed but not compressed flow chart and a signed and uncompressed PCI device driver image layout, respectively.

The field values for the EFI PCI Expansion ROM Header and the PCIR Data Structure would be as follows in this recommended PCI Driver image layout. An image must start at a 512-byte boundary, and the end of the image must be padded to the next 512-byte boundary.

Table 14.47: Recommended PCI Device Driver Layout

Offset	**Byte Length**	**Value**	**Description**
0x00	1	0x55	ROM Signature, byte 1
0x01	1	0xAA	ROM Signature, byte 2

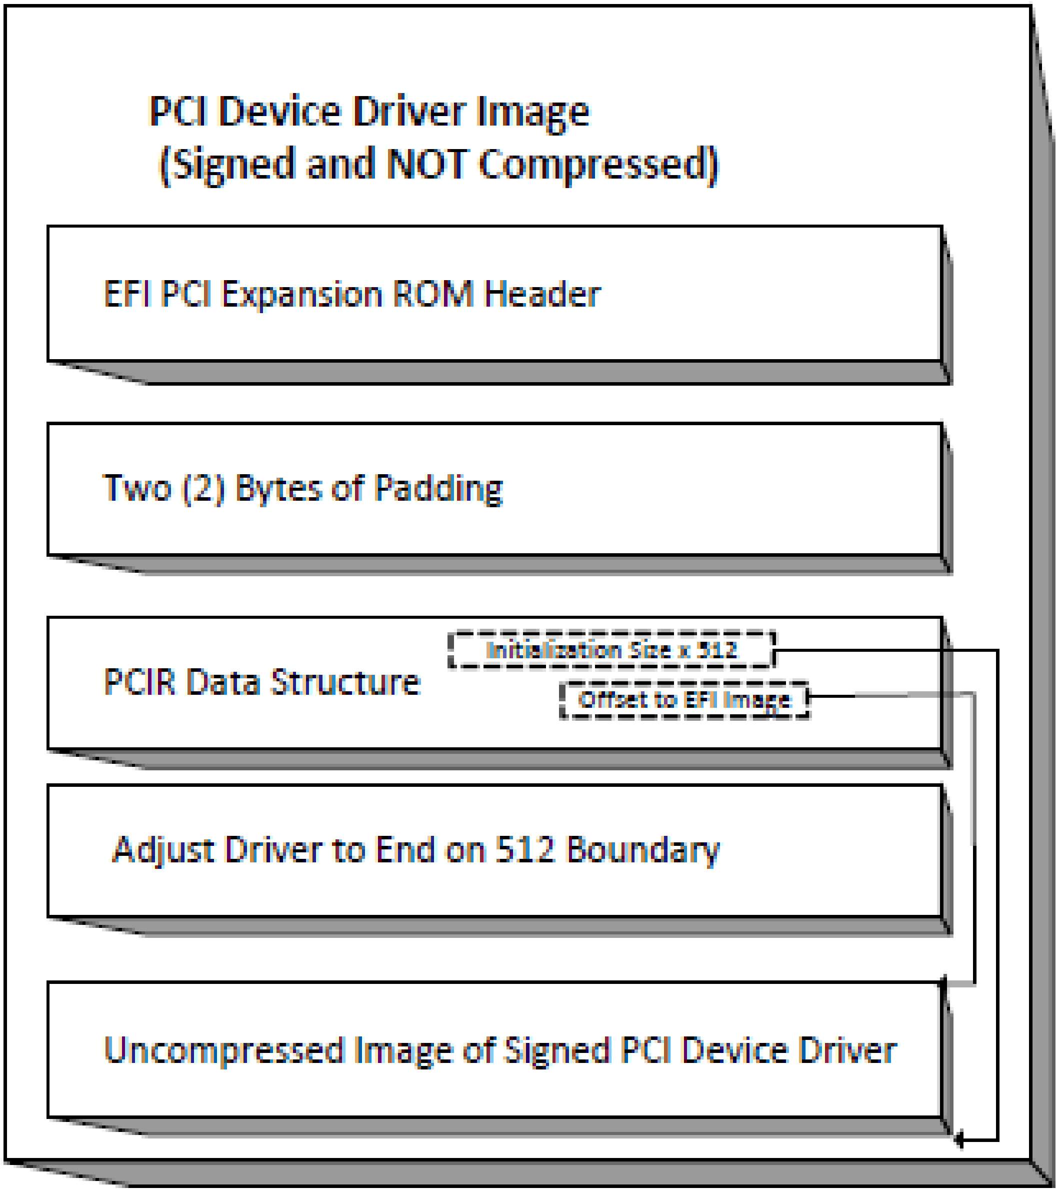

Fig. 14.19: Signed and Uncompressed PCI Driver Image Layout

14.4.24 Nonvolatile Storage

A PCI adapter may contain some form of nonvolatile storage. Since there are no standard access mechanisms for nonvolatile storage on PCI adapters, the PCI I/O Protocol does not provide any services for nonvolatile storage. However, a PCI Device Driver may choose to implement its own access mechanisms. If there is a private channel between a PCI Controller and a nonvolatile storage device, a PCI Device Driver can use it for configuration options or vital product data.

Note: *The fields RomImage and RomSize in the PCI I/O Protocol do not provide direct access to the PCI Option ROM on a PCI adapter. Instead, they provide access to a copy of the PCI Option ROM in memory. If the contents of the RomImage are modified, only the memory copy is updated. If a vendor wishes to update the contents of a PCI Option ROM, they must provide their own utility or driver to perform this task. There is no guarantee that the BAR for the PCI Option ROM is valid at the time that the utility or driver may execute, so the utility or driver must provide the code required to gain write access to the PCI Option ROM contents. The algorithm for gaining write access to a PCI Option ROM is both platform specific and adapter specific, so it is outside the scope of this document.*

14.4.25 PCI Hot-Plug Events

It is possible to design a PCI Bus Driver to work with PCI Bus that conforms to the PCI Hot-Plug Specification. There are two levels of functionality that could be provided in the preboot environment. The first is to initialize the PCI Hot-Plug capable bus so it can be used by an operating system that also conforms to the PCI Hot-Plug Specification. This only affects the PCI Enumeration that is performed in either the PCI Bus Driver's initialization, or a firmware component that executes prior to the PCI Bus Driver's initialization. None of the PCI Device Drivers need to be aware of the fact that a PCI Controller may exist in a slot that is capable of a hot-plug event. Also, the addition, removal, and replacement of PCI adapters in the preboot environment would not be allowed.

The second level of functionality is to actually implement the full hot-plug capability in the PCI Bus Driver. This is not recommended because it adds a great deal of complexity to the PCI Bus Driver design with very little added value. However, there is nothing about the PCI Driver Model that would preclude this implementation. It would require using an event based periodic timer to monitor the hot-plug capable slots, and take advantage of the *EFI_BOOT_SERVICES.ConnectController()* and *EFI_BOOT_SERVICES.DisconnectController()* Boot Services to dynamically start and stop the drivers that manage the PCI controller that is being added, removed, or replaced. If the *EFI_BOOT_SERVICES.DisconnectController()* Boot Service fails it must be retried via a periodic timer.

CHAPTER

FIFTEEN

PROTOCOLS — SCSI DRIVER MODELS AND BUS SUPPORT

The intent of this chapter is to specify a method of providing direct access to SCSI devices. These protocols provide services that allow a generic driver to produce the Block I/O protocol for SCSI disk devices, and allows an EFI utility to issue commands to any SCSI device. The main reason to provide such an access is to enable S.M.A.R.T. functionality during POST (i.e., issuing Mode Sense, Mode Select, and Log Sense to SCSI devices). This is accomplished by using a generic API such as SCSI Pass Thru. The use of this method will enable additional functionality in the future without modifying the EFI SCSI Pass Thru driver. SCSI Pass Thru is not limited to SCSI channels. It is applicable to all channel technologies that utilize SCSI commands such as SCSI, ATAPI, and Fibre Channel. This chapter describes the SCSI Driver Model. This includes the behavior of SCSI Bus Drivers, the behavior of SCSI Device Drivers, and a detailed description of the SCSI I/O Protocol. This chapter provides enough material to implement a SCSI Bus Driver, and the tools required to design and implement SCSI Device Drivers. It does not provide any information on specific SCSI devices.

15.1 SCSI Driver Model Overview

The EFI SCSI Driver Stack includes the SCSI Pass Thru Driver, SCSI Bus Driver and individual SCSI Device Drivers.

SCSI Pass Thru Driver: A SCSI Pass Through Driver manages a SCSI Host Controller that contains one or more SCSI Buses. It creates SCSI Bus Controller Handles for each SCSI Bus, and attaches Extended SCSI Pass Thru Protocol and Device Path Protocol to each handle the driver produced. Please refer to *Extended SCSI Pass Thru Protocol* and Appendix G. *Using the EFI Extended SCSI Pass Thru Protocol*.

SCSI Bus Driver: A SCSI Bus Driver manages a SCSI Bus Controller Handle that is created by SCSI Pass Thru Driver. It creates SCSI Device Handles for each SCSI Device Controller detected during SCSI Bus Enumeration, and attaches SCSI I/O Protocol and Device Path Protocol to each handle the driver produced.

SCSI Device Driver: A SCSI Device Driver manages one kind of SCSI Device. Device handles for SCSI Devices are created by SCSI Bus Drivers. A SCSI Device Driver could be a bus driver itself, and may create child handles. But most SCSI Device Drivers will be device drivers that do not create new handles. For the pure device driver, it attaches protocol instance to the device handle of the SCSI Device. These protocol instances are I/O abstractions that allow the SCSI Device to be used in the pre-boot environment. The most common I/O abstractions are used to boot an EFI compliant OS.

15.2 SCSI Bus Drivers

A SCSI Bus Driver manages a SCSI Bus Controller Handle. A SCSI Bus Controller Handle is created by a SCSI Pass Thru Driver and is abstracted in software with the Extended SCSI Pass Thru Protocol. A SCSI Bus Driver will manage handles that contain this protocol. The Figure below, *Device Handle for a SCSI Bus Controller* , shows an example device handle for a SCSI Bus handle. It contains a Device Path Protocol instance and a Extended SCSI Pass Thru Protocol Instance.

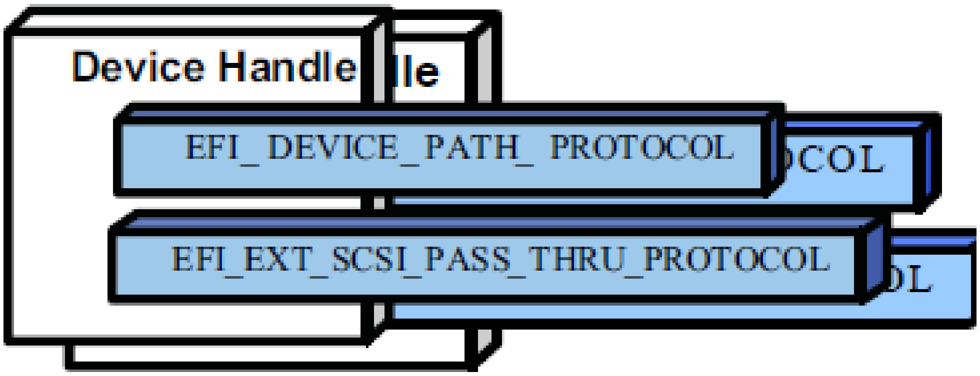

Fig. 15.1: Device Handle for a SCSI Bus Controller

15.2.1 Driver Binding Protocol for SCSI Bus Drivers

The Driver Binding Protocol contains three services. These are *Supported()* , *Start()* , and *Stop()* . *Supported()* tests to see if the SCSI Bus Driver can manage a device handle. A SCSI Bus Driver can only manage device handle that contain the Device Path Protocol and the Extended SCSI Pass Thru Protocol, so a SCSI Bus Driver must look for these two protocols on the device handle that is being tested.

The *Start()* function tells the SCSI Bus Driver to start managing a device handle. The device handle should support the protocols shown in Figure *Device Handle for a SCSI Bus Controller* . The Extended SCSI Pass Thru Protocol provides information about a SCSI Channel and the ability to communicate with any SCSI devices attached to that SCSI Channel.

The SCSI Bus Driver has the option of creating all of its children in one call to *Start()*, or spreading it across several calls to *Start()* . In general, if it is possible to design a bus driver to create one child at a time, it should do so to support the rapid boot capability in the UEFI Driver Model. Each of the child device handles created in *Start()* must contain a Device Path Protocol instance, and a SCSI I/O protocol instance. The SCSI I/O Protocol is described in *EFI SCSI I/O Protocol* and Section 14.4 . The format of device paths for SCSI Devices is described in *SCSI Device Paths*. The Figure below, *Child Handle Created by a SCSI Bus Driver* , shows an example child device handle that is created by a SCSI Bus Driver for a SCSI Device.

A SCSI Bus Driver must perform several steps to manage a SCSI Bus.

1. Scan for the SCSI Devices on the SCSI Channel that connected to the SCSI Bus Controller. If a request is being made to scan only one SCSI Device, then only looks for the one specified. Create a device handle for the SCSI Device found.
2. Install a Device Path Protocol instance and a SCSI I/O Protocol instance on the device handle created for each SCSI Device.

The *Stop()* function tells the SCSI Bus Driver to stop managing a SCSI Bus. The *Stop()* function can destroy one or more of the device handles that were created on a previous call to *Start()* . If all of the child device handles have been

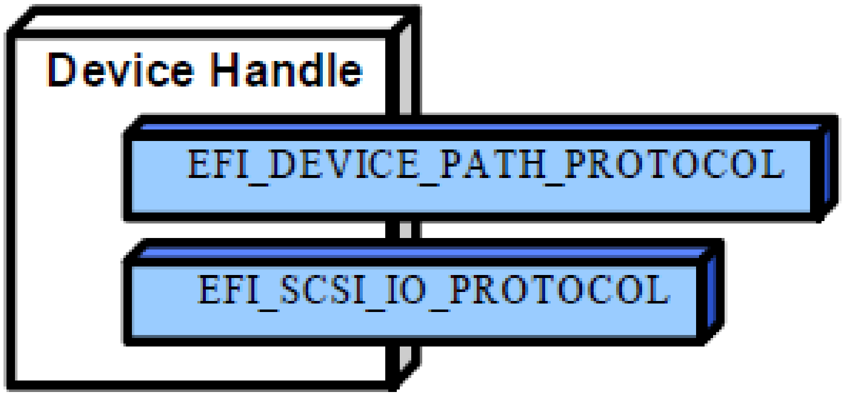

Fig. 15.2: Child Handle Created by a SCSI Bus Driver

destroyed, then *Stop()* will place the SCSI Bus Controller in a quiescent state. The functionality of *Stop()* mirrors *Start()* .

15.2.2 SCSI Enumeration

The purpose of the SCSI Enumeration is only to scan for the SCSI Devices attached to the specific SCSI channel. The SCSI Bus driver need not allocate resources for SCSI Devices (like PCI Bus Drivers do), nor need it connect a SCSI Device with its Device Driver (like USB Bus Drivers do). The details of the SCSI Enumeration is implementation specific, thus is out of the scope of this document.

15.3 SCSI Device Drivers

SCSI Device Drivers manage SCSI Devices. Device handles for SCSI Devices are created by SCSI Bus Drivers. A SCSI Device Driver could be a bus driver itself, and may create child handles. But most SCSI Device Drivers will be device drivers that do not create new handles. For the pure device driver, it attaches protocol instance to the device handle of the SCSI Device. These protocol instances are I/O abstractions that allow the SCSI Device to be used in the pre-boot environment. The most common I/O abstractions are used to boot an EFI compliant OS.

15.3.1 Driver Binding Protocol for SCSI Device Drivers

The Driver Binding Protocol contains three services. These are *Supported()* , *Start()* , and *Stop()* . *Supported()* tests to see if the SCSI Device Driver can manage a device handle. A SCSI Device Driver can only manage device handle that contain the Device Path Protocol and the SCSI I//O Protocol, so a SCSI Device Driver must look for these two protocols on the device handle that is being tested. In addition, it needs to check to see if the device handle represents a SCSI Device that SCSI Device Driver knows how to manage. This is typically done by using the services of the SCSI I/O Protocol to see whether the device information retrieved is supported by the device driver.

The *Start()* function tells the SCSI Device Driver to start managing a SCSI Device. A SCSI Device Driver could be a bus driver itself, and may create child handles. But most SCSI Device Drivers will be device drivers that do not create new handles. For the pure device driver, it installs one or more addition protocol instances on the device handle for the SCSI Device.

The *Stop()* function mirrors the *Start()* function, so the *Stop()* function completes any outstanding transactions to the SCSI Device and removes the protocol interfaces that were installed in *Start()* .

15.4 EFI SCSI I/O Protocol

This section defines the EFI SCSI I/O protocol. This protocol is used by code, typically drivers, running in the EFI boot services environment to access SCSI devices. In particular, functions for managing devices on SCSI buses are defined here.

The interfaces provided in the *EFI_SCSI_IO_PROTOCOL* are for performing basic operations to access SCSI devices.

15.4.1 EFI_SCSI_IO_PROTOCOL

This section provides a detailed description of the *EFI_SCSI_IO_PROTOCOL*.

Summary

Provides services to manage and communicate with SCSI devices.

GUID

```
#define EFI_SCSI_IO_PROTOCOL_GUID \
  {0x932f47e6,0x2362,0x4002,\
    {0x80,0x3e,0x3c,0xd5,0x4b,0x13,0x8f,0x85}}
```

Protocol Interface Structure

```
typedef struct _EFI_SCSI_IO_PROTOCOL {
  EFI_SCSI_IO_PROTOCOL_GET_DEVICE_TYPE       GetDeviceType;
  EFI_SCSI_IO_PROTOCOL_GET_DEVICE_LOCATION   GetDeviceLocation;
  EFI_SCSI_IO_PROTOCOL_RESET_BUS             ResetBus;
  EFI_SCSI_IO_PROTOCOL_RESET_DEVICE          ResetDevice;
  EFI_SCSI_IO_PROTOCOL_EXECUTE_SCSI_COMMAND  ExecuteScsiCommand;
  UINT32                                     IoAlign;
  } EFI_SCSI_IO_PROTOCOL;
```

Parameters

IoAlign

Supplies the alignment requirement for any buffer used in a data transfer. *IoAlign* values of 0 and 1 mean that the buffer can be placed anywhere in memory. Otherwise, *IoAlign* must be a power of 2, and the requirement is that the start address of a buffer must be evenly divisible by *IoAlign* with no remainder.

GetDeviceType

Retrieves the information of the device type which the SCSI device belongs to *EFI_SCSI_IO_PROTOCOL.GetDeviceType()* .

GetDeviceLocation

Retrieves the device location information in the SCSI bus *EFI_SCSI_IO_PROTOCOL.GetDeviceLocation()*.

ResetBus

Resets the entire SCSI bus the SCSI device attaches to *EFI_SCSI_IO_PROTOCOL.ResetBus()*.

ResetDevice
Resets the SCSI Device that is specified by the device handle the SCSI I/O protocol attaches *EFI_SCSI_IO_PROTOCOL.ResetDevice()* .

ExecuteScsiCommand
Sends a SCSI command to the SCSI device and waits for the execution completion until an exit condition is met, or a timeout occurs *EFI_SCSI_IO_PROTOCOL.ExecuteScsiCommand()* .

Description

The *EFI_SCSI_IO_PROTOCOL* provides the basic functionalities to access and manage a SCSI Device. There is one *EFI_SCSI_IO_PROTOCOL* instance for each SCSI Device on a SCSI Bus. A device driver that wishes to manage a SCSI Device in a system will have to retrieve the *EFI_SCSI_IO_PROTOCOL* instance that is associated with the SCSI Device. A device handle for a SCSI Device will minimally contain an *EFI_DEVICE_PATH_PROTOCOL* instance and an *EFI_SCSI_IO_PROTOCOL* instance.

15.4.2 EFI_SCSI_IO_PROTOCOL.GetDeviceType()

Summary

Retrieves the device type information of the SCSI Device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SCSI_IO_PROTOCOL_GET_DEVICE_TYPE) (
  IN EFI_SCSI_IO_PROTOCOL        *This,
  OUT UINT8                      *DeviceType
  );
```

Parameters

This
A pointer to the EFI_SCSI_IO_PROTOCOL instance. Type EFI_SCSI_IO_PROTOCOL is defined in *EFI_SCSI_IO_PROTOCOL* .

DeviceType
A pointer to the device type information retrieved from the SCSI Device. See “Related Definitions” for the possible returned values of this parameter.

Description

This function is used to retrieve the SCSI device type information. This function is typically used for SCSI Device Drivers to quickly recognize whether the SCSI Device could be managed by it.

If *DeviceType* is **NULL** , then *EFI_INVALID_PARAMETER* is returned. Otherwise, the device type is returned in *DeviceType* and *EFI_SUCCESS* is returned.

Related Definitions

```
//Defined in the SCSI Primary Commands standard (e.g., SPC-4)
//
#define EFI_SCSI_IO_TYPE_DISK                0x00 // Disk device

                       // writer device
#define MFI_SCSI_IO_TYPE_BRIDGE             0x10 // Bridge Controller
                       // Commands
#define MFI_SCSI_IO_TYPE_OSD                0x11 // Object-based Storage
                       // Device
#define EFI_SCSI_IO_TYPE_RESERVED_LOW       0x12 // Reserved (low)
#define EFI_SCSI_IO_TYPE_RESERVED_HIGH      0x1E // Reserved (high)
#define EFI_SCSI_IO_TYPE_UNKNOWN            0x1F // Unknown no device type
```

Status Codes Returned

EFI_SUCCESS	Retrieves the device type information successfully.
EFI_INVALID_PARAMETER	The DeviceType is **NULL**.

15.4.3 EFI_SCSI_IO_PROTOCOL.GetDeviceLocation()

Summary

Retrieves the SCSI device location in the SCSI channel.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SCSI_IO_PROTOCOL_GET_DEVICE_LOCATION) (
  IN EFI_SCSI_IO_PROTOCOL                *This,
  IN OUT UINT8                           **Target,
  OUT UINT64                             *Lun
  );
```

Parameters

This

A pointer to the EFI_SCSI_IO_PROTOCOL instance. Type EFI_SCSI_IO_PROTOCOL is defined in *EFI_SCSI_IO_PROTOCOL* .

Target

A pointer to the Target Array which represents the ID of a SCSI device on the SCSI channel.

Lun

A pointer to the Logical Unit Number of the SCSI device on the SCSI channel.

Description

This function is used to retrieve the SCSI device location in the SCSI bus. The device location is determined by a (Target, Lun) pair. This function allows a SCSI Device Driver to retrieve its location on the SCSI channel, and may use the Extended SCSI Pass Thru Protocol to access the SCSI device directly.

If *Target* or *Lun* is **NULL** , then *EFI_INVALID_PARAMETER* is returned. Otherwise, the device location is returned in *Target* and *Lun* , and *EFI_SUCCESS* is returned.

Status Codes Returned

EFI_SUCCESS	Retrieves the device location successfully.
EFI_INVALID_PARAMETER	Target or Lun is *NULL*.

15.4.4 EFI_SCSI_IO_PROTOCOL.ResetBus()

Summary

Resets the SCSI Bus that the SCSI Device is attached to.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SCSI_IO_PROTOCOL_RESET_BUS) (
  IN EFI_SCSI_IO_PROTOCOL            *This
  );
```

Parameters

This

A pointer to the EFI_SCSI_IO_PROTOCOL instance. Type EFI_SCSI_IO_PROTOCOL is defined in *EFI_SCSI_IO_PROTOCOL* .

Description

This function provides the mechanism to reset the whole SCSI bus that the specified SCSI Device is connected to. Some SCSI Host Controller may not support bus reset, if so, *EFI_UNSUPPORTED* is returned. If a device error occurs while executing that bus reset operation, then *EFI_DEVICE_ERROR* is returned. If a timeout occurs during the execution of the bus reset operation, then *EFI_TIMEOUT* is returned. If the bus reset operation is completed, then *EFI_SUCCESS* is returned.

Status Codes Returned

EFI_SUCCESS	The SCSI bus is reset successfully.
EFI_DEVICE_ERROR	Errors encountered when resetting the SCSI bus.
EFI_UNSUPPORTED	The bus reset operation is not supported by the SCSI Host Controller.
EFI_TIMEOUT	A timeout occurred while attempting to reset the SCSI bus.

15.4.5 EFI_SCSI_IO_PROTOCOL.ResetDevice()

Summary

Resets the SCSI Device that is specified by the device handle that the SCSI I/O Protocol is attached.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_SCSI_IO_PROTOCOL_RESET_DEVICE) (
  IN EFI_SCSI_IO_PROTOCOL         *This
  );
```

Parameters

This

A Pointer to the EFI_SCSI_IO_PROTOCOL instance. Type EFI_SCSI_IO_PROTOCOL is defined in *EFI_SCSI_IO_PROTOCOL* .

Description

This function provides the mechanism to reset the SCSI Device. If the SCSI bus does not support a device reset operation, then *EFI_UNSUPPORTED* is returned. If a device error occurs while executing that device reset operation, then *EFI_DEVICE_ERROR* is returned. If a timeout occurs during the execution of the device reset operation, then *EFI_TIMEOUT* is returned. If the device reset operation is completed, then *EFI_SUCCESS* is returned.

Status Codes Returned

EFI_SUCCESS	Reset the SCSI Device successfully.
EFI_DEVICE_ERROR	Errors are encountered when resetting the SCSI Device.
EFI_UNSUPPORTED	The SCSI bus does not support a device reset operation.
EFI_TIMEOUT	A timeout occurred while attempting to reset the SCSI Device.

15.4.6 EFI_SCSI_IO_PROTOCOL.ExecuteScsiCommand()

Summary

Sends a SCSI Request Packet to the SCSI Device for execution.

Prototype

```
typedef
  EFI_STATUS
  (EFIAPI *EFI_SCSI_IO_PROTOCOL_EXECUTE_SCSI_COMMAND) (
    IN EFI_SCSI_IO_PROTOCOL                 *This,
    IN OUT EFI_SCSI_IO_SCSI_REQUEST_PACKET   *Packet,
    IN EFI_EVENT                            Event OPTIONAL
    );
```

Parameters

This

A pointer to the EFI_SCSI_IO_PROTOCOL instance. Type EFI_SCSI_IO_PROTOCOL is defined in defined in *EFI_SCSI_IO_PROTOCOL* .

Packet

The SCSI request packet to send to the SCSI Device specified by the device handle. See "Related Definitions" for a description of EFI_SCSI_IO_SCSI_REQUEST_PACKET.

Event

If the SCSI bus where the SCSI device is attached does not support non-blocking I/O, then Event is ignored, and blocking I/O is performed. If Event is NULL, then blocking I/O is performed. If Event is not NULL and non-blocking I/O is supported, then non-blocking I/O is performed, and Event will be signaled when the SCSI Request Packet completes.

Related Definitions

```
typedef struct {
  UINT64            Timeout;
  VOID              *InDataBuffer;
  VOID              *OutDataBuffer;
  VOID              *SenseData;
  VOID              *Cdb;
  UINT32            InTransferLength;
  UINT32            OutTransferLength;
  UINT8             CdbLength;
  UINT8             DataDirection;
  UINT8             HostAdapterStatus;
  UINT8             TargetStatus;
  UINT8             SenseDataLength;
} EFI_SCSI_IO_SCSI_REQUEST_PACKET;
```

Timeout

The timeout, in 100 ns units, to use for the execution of this SCSI Request Packet. A *Timeout* value of 0 means that this function will wait indefinitely for the SCSI Request Packet to execute. If *Timeout* is greater than zero, then this function will return *EFI_TIMEOUT* if the time required to execute the SCSI Request Packet is greater than *Timeout* .

DataBuffer

A pointer to the data buffer to transfer from or to the SCSI device.

InDataBuffer

A pointer to the data buffer to transfer between the SCSI controller and the SCSI device for SCSI READ command. For all SCSI WRITE Commands this must point to *NULL* .

OutDataBuffer

A pointer to the data buffer to transfer between the SCSI controller and the SCSI device for SCSI WRITE command. For all SCSI READ commands this field must point to *NULL* .

SenseData

A pointer to the sense data that was generated by the execution of the SCSI Request Packet.

Cdb

A pointer to buffer that contains the Command Data Block to send to the SCSI device.

InTransferLength

On Input, the size, in bytes, of *InDataBuffer* . On output, the number of bytes transferred between the SCSI controller and the SCSI device. If *InTransferLength* is larger than the SCSI controller can handle, no data will be transferred, *InTransferLength* will be updated to contain the number of bytes that the SCSI controller is able to transfer, and *EFI_BAD_BUFFER_SIZE* will be returned.

OutTransferLength

On Input, the size, in bytes of *OutDataBuffer* . On Output, the Number of bytes transferred between SCSI Controller and the SCSI device. If *OutTransferLength* is larger than the SCSI controller can handle, no data will be transferred, *OutTransferLength* will be updated to contain the number of bytes that the SCSI controller is able to transfer, and *EFI_BAD_BUFFER_SIZE* will be returned.

CdbLength
The length, in bytes, of the buffer *Cdb* . The standard values are 6, 10, 12, and 16, but other values are possible if a variable length *CDB* is used.

DataDirection
The direction of the data transfer. 0 for reads, 1 for writes. A value of 2 is Reserved for Bi-Directional SCSI commands. For example XDREADWRITE. All other values are reserved, and must not be used.

HostAdapterStatus
The status of the SCSI Host Controller that produces the SCSI bus where the SCSI device attached when the SCSI Request Packet was executed on the SCSI Controller. See the possible values listed below.

TargetStatus
The status returned by the SCSI device when the SCSI Request Packet was executed. See the possible values listed below.

SenseDataLength
On input, the length in bytes of the *SenseData* buffer. On output, the number of bytes written to the *SenseData* buffer.

```
//
// DataDirection
//
#define EFI_SCSI_IO_DATA_DIRECTION_READ            0
#define EFI_SCSI_IO_DATA_DIRECTION_WRITE           1
#define EFI_SCSI_IO_DATA_DIRECTION_BIDIRECTIONAL   2

//
// HostAdapterStatus
//
#define EFI_SCSI_IO_STATUS_HOST_ADAPTER_OK                     0x00
#define EFI_SCSI_IO_STATUS_HOST_ADAPTER_TIMEOUT_COMMAND        0x09
#define EFI_SCSI_IO_STATUS_HOST_ADAPTER_TIMEOUT                0x0b
#define EFI_SCSI_IO_STATUS_HOST_ADAPTER_MESSAGE_REJECT         0x0d
#define EFI_SCSI_IO_STATUS_HOST_ADAPTER_BUS_RESET              0x0e
#define EFI_SCSI_IO_STATUS_HOST_ADAPTER_PARITY_ERROR           0x0f

(continued from previous page)

```
#define EFI_SCSI_IO_STATUS_TARGET_COMMAND_TERMINATED           0x22
#define EFI_SCSI_IO_STATUS_TARGET_QUEUE_FULL                   0x28
```

Description

This function sends the SCSI Request Packet specified by *Packet* to the SCSI Device.

If the SCSI Bus supports non-blocking I/O and *Event* is not **NULL**, then this function will return immediately after the command is sent to the SCSI Device, and will later signal *Event* when the command has completed. If the SCSI Bus supports non-blocking I/O and *Event* is **NULL**, then this function will send the command to the SCSI Device and block until it is complete. If the SCSI Bus does not support non-blocking I/O, the *Event* parameter is ignored, and the function will send the command to the SCSI Device and block until it is complete.

If *Packet* is successfully sent to the SCSI Device, then *EFI_SUCCESS* is returned.

If *Packet* cannot be sent because there are too many packets already queued up, then *EFI_NOT_READY* is returned. The caller may retry *Packet* at a later time.

If a device error occurs while sending the *Packet* , then *EFI_DEVICE_ERROR* is returned.

If a timeout occurs during the execution of *Packet* , then *EFI_TIMEOUT* is returned.

If any field of *Packet* is invalid, then *EFI_INVALID_PARAMETER* is returned.

If the data buffer described by *DataBuffer* and *TransferLength* is too big to be transferred in a single command, then *EFI_BAD_BUFFER_SIZE* is returned. The number of bytes actually transferred is returned in *TransferLength* .

If the command described in *Packet* is not supported by the SCSI Host Controller that produces the SCSI bus, then *EFI_UNSUPPORTED* is returned.

If *EFI_SUCCESS, EFI_BAD_BUFFER_SIZE, EFI_DEVICE_ERROR* , or *EFI_TIMEOUT* is returned, then the caller must examine the status fields in *Packet* in the following precedence order: *HostAdapterStatus* followed by *TargetStatus* followed by *SenseDataLength* , followed by *SenseData* . If non-blocking I/O is being used, then the status fields in *Packet* will not be valid until the *Event* associated with *Packet* is signaled.

If *EFI_NOT_READY* , *EFI_INVALID_PARAMETER* or *EFI_UNSUPPORTED* is returned, then *Packet* was never sent, so the status fields in *Packet* are not valid. If non-blocking I/O is being used, the *Event* associated with *Packet* will not be signaled.

Status Codes Returned

EFI_SUCCESS	The SCSI Request Packet was sent by the host. For read and bi-directional commands, *InTransferLength* bytes were transferred to *InDataBuffer* . For write and bi-directional commands, *OutTransferLength* bytes were transferred from *OutDataBuffer* . See *HostAdapterStatus, TargetStatus, SenseDataLength,* and *SenseData* in that order for additional status information.
EFI_BAD_BUFFER_SIZE	The SCSI Request Packet was not executed. For read and bi-directional commands, the number of bytes that could be transferred is returned in *InTransferLength.* For write and bi-directional commands, the number of bytes that could be transferred is returned in *OutTransferLength.* See *HostAdapterStatus* and *TargetStatus* in that order for additional status information.
EFI_NOT_READY	The SCSI Request Packet could not be sent because there are too many SCSI Command Packets already queued. The caller may retry again later.
EFI_DEVICE_ERROR	A device error occurred while attempting to send the SCSI Request Packet. See HostAdapterStatus, TargetStatus, SenseDataLength, and SenseData in that order for additional status information.

continues on next page

Table 15.3 – continued from previous page

EFI_INVALID_PARAMETER	The contents of CommandPacket are invalid. The SCSI Request Packet was not sent, so no additional status information is available.
EFI_UNSUPPORTED	The command described by the SCSI Request Packet is not supported by the SCSI initiator (i.e., SCSI Host Controller). The SCSI Request Packet was not sent, so no additional status information is available.
EFI_TIMEOUT	A timeout occurred while waiting for the SCSI Request Packet to execute. See HostAdapterStatus, TargetStatus, SenseDataLength, and SenseData in that order for additional status information.

15.5 SCSI Device Paths

An *EFI_SCSI_IO_PROTOCOL* must be installed on a handle for its services to be available to SCSI device drivers. In addition to the *EFI_SCSI_IO_PROTOCOL* , an *EFI_DEVICE_PATH_PROTOCOL* must also be installed on the same handle. See *Protocols – Device Path Protocol* for detailed description of the *EFI_DEVICE_PATH_PROTOCOL* .

The SCSI Driver Model defined in this document can support the SCSI channel generated or emulated by multiple architectures, such as Parallel SCSI, ATAPI, Fibre Channel, InfiniBand, and other future channel types. In this section, there are four example device paths provided, including SCSI device path, ATAPI device path, Fibre Channel device path and InfiniBand device path.

15.5.1 SCSI Device Path Example

Table 15.4 shows an example device path for a SCSI device controller on a desktop platform. This SCSI device controller is connected to a SCSI channel that is generated by a PCI SCSI host controller. The PCI SCSI host controller generates a single SCSI channel, it is located at PCI device number 0x07 and PCI function 0x00, and is directly attached to a PCI root bridge. The SCSI device controller is assigned SCSI Id 2, and its LUN is 0.

This sample device path consists of an ACPI Device Path Node, a PCI Device Path Node, a SCSI Node, and a Device Path End Structure. The _HID and _UID must match the ACPI table description of the PCI Root Bridge. The shorthand notation for this device path is:

```
ACPI(PNP0A03,0)/PCI(7,0)/SCSI(2,0).
```

Table 15.4: SCSI Device Path Examples

Byte Offset	**Byte Length**	**Data**	**Description**
0x00	0x01	0x02	Generic Device Path Header - Type ACPI Device Path
0x01	0x01	0x01	Sub type - ACPI Device Path
0x02	0x02	0x0C	Length - 0x0C bytes
0x04	0x04	0x41D0, 0x0A03	_HID PNP0A03 - 0x41D0 represents the compressed string ‘PNP’ and is encoded in the low order bytes. The compression method is described in the ACPI Specification.
0x08	0x04	0x0000	_UID
0x0C	0x01	0x01	Generic Device Path Header - Type Hardware Device Path
0x0D	0x01	0x01	Sub type - PCI
0x0E	0x02	0x06	Length - 0x06 bytes
0x10	0x01	0x07	PCI Function
0x11	0x01	0x00	PCI Device
0x12	0x01	0x03	Generic Device Path Header - Type Message Device Path

continues on next page

Table 15.4 – continued from previous page

0x13	0x01	0x02	Sub type - SCSI
0x14	0x02	0x08	Length - 0x08 bytes
0x16	0x02	0x0002	Target ID on the SCSI bus (PUN)
0x18	0x02	0x0000	Logical Unit Number (LUN)
0x1A	0x01	0x7F	Generic Device Path Header - Type End of Hardware Device Path
0x1B	0x01	0xFF	Sub type - End of Entire Device Path
0x1C	0x02	0x04	Length - 0x04 bytes

15.5.2 ATAPI Device Path Example

The Table below, *ATAPI Device Path Examples* , shows an example device path for an ATAPI device on a desktop platform. This ATAPI device is connected to the IDE bus on Primary channel, and is configured as the Master device on the channel. The IDE bus is generated by the IDE controller that is a PCI device. It is located at PCI device number 0x1F and PCI function 0x01, and is directly attached to a PCI root bridge.

This sample device path consists of an ACPI Device Path Node, a PCI Device Path Node, an ATAPI Node, and a Device Path End Structure. The _HID and _UID must match the ACPI table description of the PCI Root Bridge. The shorthand notation for this device path is:

```
ACPI(PNP0A03,0)/PCI(7,0)/ATA(Primary,Master,0).
```

Table 15.5: ATAPI Device Path Examples

Byte Offset	Byte Length	Data	Description
0x00	0x01	0x02	Generic Device Path Header - Type ACPI Device Path
0x01	0x01	0x01	Sub type - ACPI Device Path
0x02	0x02	0x0C	Length - 0x0C bytes
0x04	0x04	0x41D0, 0x0A03	_HID PNP0A03 - 0x41D0 represents the compressed string 'PNP' and is encoded in the low order bytes. The compression method is described in the ACPI Specification.
0x08	0x04	0x0000	_UID
0x0C	0x01	0x01	Generic Device Path Header - Type Hardware Device Path
0x0D	0x01	0x01	Sub type - PCI
0x0E	0x02	0x06	Length - 0x06 bytes
0x10	0x01	0x07	PCI Function
0x11	0x01	0x00	PCI Device
0x12	0x01	0x03	Generic Device Path Header - Type Message Device Path
0x13	0x01	0x01	Sub type - ATAPI
0x14	0x02	0x08	Length - 0x08 bytes
0x16	0x01	0x00	P rimarySecondary - Set to zero for primary or one for secondary.
0x17	0x01	0x00	SlaveMaster - set to zero for master or one for slave.
0x18	0x02	0x0000	Logical Unit Number,LUN.
0x1A	0x01	0x7F	Generic Device Path Header - Type End of Hardware Device Path
0x1B	0x01	0xFF	Sub type - End of Entire Device Path
0x1C	0x02	0x04	Length - 0x04 bytes

15.5.3 Fibre Channel Device Path Example

Section 10.3.4.3 shows an example device path for a SCSI device that is connected to a Fibre Channel Port on a desktop platform. The Fibre Channel Port is a PCI device that is located at PCI device number 0x08 and PCI function 0x00, and is directly attached to a PCI root bridge. The Fibre Channel Port is addressed by the World Wide Number, and is assigned as X (X is a 64bit value); the SCSI device's Logical Unit Number is 0.

This sample device path consists of an ACPI Device Path Node, a PCI Device Path Node, a Fibre Channel Device Path Node, and a Device Path End Structure. The _HID and _UID must match the ACPI table description of the PCI Root Bridge. The shorthand notation for this device path is:

```
ACPI(PNP0A03,0)/PCI(8,0)/Fibre(X,0).
```

Table 15.6: Fibre Channel Device Path Examples

Byte Offset	Byte Length	Data	Description
0x00	0x01	0x02	Generic Device Path Header - Type ACPI Device Path
0x01	0x01	0x01	Sub type - ACPI Device Path
0x02	0x02	0x0C	Length - 0x0C bytes
0x04	0x04	0x41D0, 0x0A03	_HID PNP0A03 - 0x41D0 represents the compressed string 'PNP' and is encoded in the low order bytes. The compression method is described in the ACPI Specification.
0x08	0x04	0x0000	_UID
0x0C	0x01	0x01	Generic Device Path Header - Type Hardware Device Path
0x0D	0x01	0x01	Sub type - PCI
0x0E	0x02	0x06	Length - 0x06 bytes
0x10	0x01	0x08	PCI Function
0x11	0x01	0x00	PCI Device
0x12	0x01	0x03	Generic Device Path Header - Type Message Device Path
0x13	0x01	0x02	Sub type - Fibre Channel
0x14	0x02	0x24	Length - 0x24 bytes
0x16	0x04	0x00	Reserved
0x1A	0x08	X	Fibre Channel World Wide Number
0x22	0x08	0x00	Fibre Channel Logical Unit Number (LUN).
0x2A	0x01	0x7F	Generic Device Path Header - Type End of Hardware Device Path
0x2B	0x01	0xFF	Sub type - End of Entire Device Path
0x2C	0x02	0x04	Length - 0x04 bytes

15.5.4 InfiniBand Device Path Example

The Table below, *InfiniBand Device Path Examples* , shows an example device path for a SCSI device in an InfiniBand Network. This SCSI device is connected to a single SCSI channel generated by a SCS Host Adapter, and the SCSI Host Adapter is an end node in the InfiniBand Network. The SCSI Host Adapter is a PCI device that is located at PCI device number 0x07 and PCI function 0x00, and is directly attached to a PCI root bridge. The SCSI device is addressed by the (IOU X, IOC Y, DeviceId Z) in the InfiniBand Network. (X, Y, Z are EUI-64 compliant identifiers).

This sample device path consists of an ACPI Device Path Node, a PCI Device Path Node, an InfiniBand Node, and a Device Path End Structure. The _HID and _UID must match the ACPI table description of the PCI Root Bridge. The shorthand notation for this device path is:

```
ACPI(PNP0A03,0)/PCI(7,0)/Infiniband(X,Y,Z).
```

Table 15.7: InfiniBand Device Path Examples

Byte Offset	Byte Length	Data	Description
0x00	0x01	0x02	Generic Device Path Header - Type ACPI Device Path
0x01	0x01	0x01	Sub type - ACPI Device Path
0x02	0x02	0x0C	Length - 0x0C bytes
0x04	0x04	0x41D0, 0x0A03	_HID PNP0A03 - 0x41D0 represents the compressed string 'PNP' and is encoded in the low order bytes. The compression method is described in the ACPI Specification.
0x08	0x04	0x0000	_UID
0x0C	0x01	0x01	Generic Device Path Header - Type Hardware Device Path
0x0D	0x01	0x01	Sub type - PCI
0x0E	0x02	0x06	Length - 0x06 bytes
0x10	0x01	0x07	PCI Function
0x11	0x01	0x00	PCI Device
0x12	0x01	0x03	Generic Device Path Header - Type Message Device Path
0x13	0x01	0x09	Sub type - InfiniBand
0x14	0x02	0x20	Length - 0x20 bytes
0x16	0x04	0x00	Reserved
0x1A	0x08	X	64bit node GUID of the IOU
0x22	0x08	Y	64bit GUID of the IOC
0x2A	0x08	Z	64bit persistent ID of the device.
0x32	0x01	0x7F	Generic Device Path Header - Type End of Hardware Device Path
0x33	0x01	0xFF	Sub type - End of Entire Device Path
0x34	0x02	0x04	Length - 0x04 bytes

15.6 SCSI Pass Thru Device Paths

An *EFI_EXT_SCSI_PASS_THRU_PROTOCOL* must be installed on a handle for its services to be available to UEFI drivers and applications. In addition to the *EFI_EXT_SCSI_PASS_THRU_PROTOCOL* , *EFI Device Path Protocol* must also be installed on the same handle. See *Protocols – Device Path Protocol* for a detailed description of the *EFI_DEVICE_PATH_PROTOCOL* .

A device path describes the location of a hardware component in a system from the processor's point of view. This includes the list of busses that lie between the processor and the SCSI controller. The EFI Specification takes advantage of the ACPI Specification to name system components. For the following set of examples, a PCI SCSI controller is assumed. The examples will show a SCSI controller on the root PCI bus, and a SCSI controller behind a PCI-PCI bridge. In addition, an example of a multichannel SCSI controller will be shown.

See *Single Channel PCI SCSI Controller* shows an example device path for a single channel PCI SCSI controller that is located at PCI device number 0x07 and PCI function 0x00, and is directly attached to a PCI root bridge. This device path consists of an ACPI Device Path Node, a PCI Device Path Node, and a Device Path End Structure. The _HID and _UID must match the ACPI table description of the PCI Root Bridge. The shorthand notation for this device path is:

```
ACPI(PNP0A03,0)/PCI(7,0).
```

Table 15.8: Single Channel PCI SCSI Controller

Byte Offset	Byte Length	Data	Description
0x00	0x01	0x02	Generic Device Path Header - Type ACPI Device Path
0x01	0x01	0x01	Sub type - ACPI Device Path
0x02	0x02	0x0C	Length - 0x0C bytes
0x04	0x04	0x41D0, 0x0A03	_HID PNP0A03 - 0x41D0 represents the compressed string 'PNP' and is encoded in the low order bytes. The compression method is described in the ACPI Specification.
0x08	0x04	0x0000	_UID
0x0C	0x01	0x01	Generic Device Path Header - Type Hardware Device Path
0x0D	0x01	0x01	Sub type - PCI
0x0E	0x02	0x06	Length - 0x06 bytes
0x10	0x01	0x00	PCI Function
0x11	0x01	0x07	PCI Device
0x12	0x01	0x7F	Generic Device Path Header - Type End of Hardware Device Path
0x13	0x01	0xFF	Sub type - End of Entire Device Path
0x14	0x02	0x04	Length - 0x04 bytes

The Table below, *Single Channel PCI SCSI Controller Behind a PCI Bridge* , shows an example device path for a single channel PCI SCSI controller that is located behind a PCI to PCI bridge at PCI device number 0x07 and PCI function 0x00. The PCI to PCI bridge is directly attached to a PCI root bridge, and it is at PCI device number 0x05 and PCI function 0x00. This device path consists of an ACPI Device Path Node, two PCI Device Path Nodes, and a Device Path End Structure. The _HID and _UID must match the ACPI table description of the PCI Root Bridge. The shorthand notation for this device path is:

```
ACPI(PNP0A03,0)/PCI(5,0)/PCI(7,0).
```

Table 15.9: Single Channel PCI SCSI Controller Behind a PCI Bridge

Byte Offset	Byte Length	Data	Description
0x00	0x01	0x02	Generic Device Path Header - Type ACPI Device Path
0x01	0x01	0x01	Sub type - ACPI Device Path
0x02	0x02	0x0C	Length - 0x0C bytes
0x04	0x04	0x41D0, 0x0A03	_HID PNP0A03 - 0x41D0 represents the compressed string 'PNP' and is encoded in the low order bytes. The compression method is described in the ACPI Specification.
0x08	0x04	0x0000	_UID
0x0C	0x01	0x01	Generic Device Path Header - Type Hardware Device Path
0x0D	0x01	0x01	Sub type - PCI
0x0E	0x02	0x06	Length - 0x06 bytes
0x10	0x01	0x00	PCI Function
0x11	0x01	0x05	PCI Device
0x12	0x01	0x01	Generic Device Path Header - Type Hardware Device Path
0x13	0x01	0x01	Sub type - PCI
0x14	0x02	0x06	Length - 0x06 bytes
0x16	0x01	0x00	PCI Function
0x17	0x01	0x07	PCI Device
0x18	0x01	0x7F	Generic Device Path Header - Type End of Hardware Device Path
0x19	0x01	0xFF	Sub type - End of Entire Device Path
0x1A	0x02	0x04	Length - 0x04 bytes

Table 15.10 shows an example device path for channel #3 of a four channel PCI SCSI controller that is located behind a PCI to PCI bridge at PCI device number 0x07 and PCI function 0x00. The PCI to PCI bridge is directly attached to a PCI root bridge, and it is at PCI device number 0x05 and PCI function 0x00. This device path consists of an ACPI Device Path Node, two PCI Device Path Nodes, a Controller Node, and a Device Path End Structure. The _HID and _UID must match the ACPI table description of the PCI Root Bridge. The shorthand notation of the device paths for all four of the SCSI channels are listed below:

```
ACPI(PNP0A03,0)/PCI(5,0)/PCI(7,0)/Ctrl(0)
ACPI(PNP0A03,0)/PCI(5,0)/PCI(7,0)/Ctrl(1)
ACPI(PNP0A03,0)/PCI(5,0)/PCI(7,0)/Ctrl(2)
ACPI(PNP0A03,0)/PCI(5,0)/PCI(7,0)/Ctrl(3)
```

The following table shows the last device path listed.

Table 15.10: Channel #3 of a PCI SCSI Controller behind a PCIBridge

Byte Offset	Byte Length	Data	Description
0x00	0x01	0x02	Generic Device Path Header - Type ACPI Device Path
0x01	0x01	0x01	Sub type - ACPI Device Path

0x22	0x02	0x04	Length - 0x04 bytes

15.7 Extended SCSI Pass Thru Protocol

This section defines the Extended SCSI Pass Thru Protocol. This protocol allows information about a SCSI channel to be collected, and allows SCSI Request Packets to be sent to any SCSI devices on a SCSI channel even if those devices are not boot devices. This protocol is attached to the device handle of each SCSI channel in a system that the protocol supports, and can be used for diagnostics. It may also be used to build a Block I/O driver for SCSI hard drives and SCSI CD-ROM or DVD drives to allow those devices to become boot devices. As ATAPI cmds are derived from SCSI cmds, the above statements also are applicable for ATAPI devices attached to a ATA controller. Packet-based commands(ATAPI cmds) would be sent to ATAPI devices only through the Extended SCSI Pass Thru Protocol.

15.7.1 EFI_EXT_SCSI_PASS_THRU_PROTOCOL

This section provides a detailed description of the *EFI_EXT_SCSI_PASS_THRU_PROTOCOL* .

Summary

Provides services that allow SCSI Pass Thru commands to be sent to SCSI devices attached to a SCSI channel. It also allows packet-based commands (ATAPI cmds) to be sent to ATAPI devices attached to a ATA controller.

GUID

```
#define EFI_EXT_SCSI_PASS_THRU_PROTOCOL_GUID \
  {0x143b7632, 0xb81b, 0x4cb7,\
    {0xab, 0xd3, 0xb6, 0x25, 0xa5, 0xb9, 0xbf, 0xfe}}
```

Protocol Interface Structure

```
typedef struct _EFI_EXT_SCSI_PASS_THRU_PROTOCOL {
  EFI_EXT_SCSI_PASS_THRU_MODE                   *Mode;
  EFI_EXT_SCSI_PASS_THRU_PASSTHRU               PassThru;
  EFI_EXT_SCSI_PASS_THRU_GET_NEXT_TARGET_LUN    GetNextTargetLun;
  EFI_EXT_SCSI_PASS_THRU_BUILD_DEVICE_PATH      BuildDevicePath;
  EFI_EXT_SCSI_PASS_THRU_GET_TARGET_LUN         GetTargetLun;
  EFI_EXT_SCSI_PASS_THRU_RESET_CHANNEL          ResetChannel;
  EFI_EXT_SCSI_PASS_THRU_RESET_TARGET_LUN       ResetTargetLun;
  EFI_EXT_SCSI_PASS_THRU_GET_NEXT_TARGE         GetNextTarget;
} EFI_EXT_SCSI_PASS_THRU_PROTOCOL;
```

Parameters

Mode

A pointer to the *EFI_EXT_SCSI_PASS_THRU_MODE* data for this SCSI channel. *EFI_EXT_SCSI_PASS_THRU_MODE* is defined in “Related Definitions” below.

PassThru

Sends a SCSI Request Packet to a SCSI device that is Connected to the SCSI channel. See the *EFI_EXT_SCSI_PASS_THRU_PROTOCOL.PassThru()* function description.

GetNextTargetLun

Retrieves the list of legal Target IDs and LUNs for the SCSI devices on a SCSI channel. See the *EFI_EXT_SCSI_PASS_THRU_PROTOCOL.GetNextTargetLun()* function description.

BuildDevicePath

Allocates and builds a device path node for a SCSI Device on a SCSI channel. See the *EFI_EXT_SCSI_PASS_THRU_PROTOCOL.BuildDevicePath()* function description.

GetTargetLun
Translates a device path node to a Target ID and LUN. See the *EFI_EXT_SCSI_PASS_THRU_PROTOCOL.GetTargetLun()* function description.

ResetChannel
Resets the SCSI channel. This operation resets all the SCSI devices connected to the SCSI channel. See the *EFI_EXT_SCSI_PASS_THRU_PROTOCOL.ResetChannel()* function description.

ResetTargetLun
Resets a SCSI device that is connected to the SCSI channel. See the *EFI_EXT_SCSI_PASS_THRU_PROTOCOL.ResetTargetLun()* function description.

GetNextTartget
Retrieves the list of legal Target IDs for the SCSI devices on a SCSI channel. See the *EFI_EXT_SCSI_PASS_THRU_PROTOCOL.GetNextTarget()* function description.

The following data values in the *EFI_EXT_SCSI_PASS_THRU_MODE* interface are read-only.

AdapterId
The Target ID of the host adapter on the SCSI channel.

Attributes
Additional information on the attributes of the SCSI channel. See "Related Definitions" below for the list of possible attributes.

IoAlign
Supplies the alignment requirement for any buffer used in a data transfer. *IoAlign* values of 0 and 1 mean that the buffer can be placed anywhere in memory. Otherwise, *IoAlign* must be a power of 2, and the requirement is that the start address of a buffer must be evenly divisible by *IoAlign* with no remainder.

Related Definitions

```
typedef struct {
  UINT32 *AdapterId;*
  UINT32 *Attributes;*
  UINT32 *IoAlign;*
} EFI_EXT_SCSI_PASS_THRU_MODE;

#define TARGET_MAX_BYTES 0x10
#define EFI_EXT_SCSI_PASS_THRU_ATTRIBUTES_PHYSICAL 0x0001
#define EFI_EXT_SCSI_PASS_THRU_ATTRIBUTES_LOGICAL 0x0002
#define EFI_EXT_SCSI_PASS_THRU_ATTRIBUTES_NONBLOCKIO 0x0004
```

EFI_EXT_SCSI_PASS_THRU_ATTRIBUTES_PHYSICAL
If this bit is set, then the EFI_EXT_SCSI_PASS_THRU_PROTOCOL interface is for physical devices on the SCSI channel.

EFI_EXT_SCSI_PASS_THRU_ATTRIBUTES_LOGICAL
If this bit is set, then the EFI_EXT_SCSI_PASS_THRU_PROTOCOL interface is for logical devices on the SCSI channel.

EFI_EXT_SCSI_PASS_THRU_ATTRIBUTES_NONBLOCKIO
If this bit is set, then the EFI_EXT_SCSI_PASS_THRU_PROTOCOL interface supports non blocking I/O. Every EFI_EXT_SCSI_PASS_THRU_PROTOCOL must support blocking I/O. The support of nonblocking I/O is optional.

Description

The *EFI_EXT_SCSI_PASS_THRU_PROTOCOL* provides information about a SCSI channel and the ability to send SCI Request Packets to any SCSI device attached to that SCSI channel. The information includes the Target ID of the host controller on the SCSI channel and the attributes of the SCSI channel.

The printable name for the SCSI controller, and the printable name of the SCSI channel can be provided through the *EFI_COMPONENT_NAME2_PROTOCOL* for multiple languages.

The *Attributes* field of the *EFI_EXT_SCSI_PASS_THRU_PROTOCOL* interface tells if the interface is for physical SCSI devices or logical SCSI devices. Drivers for non-RAID SCSI controllers will set both the *EFI_EXT_SCSI_PASS_THRU_ATTRIBUTES_PHYSICAL* , and the *EFI_EXT_SCSI_PASS_THRU_ATTRIBUTES_LOGICAL* bits.

Drivers for RAID controllers that allow access to the physical devices and logical devices will produce two *EFI_EXT_SCSI_PASS_THRU_PROTOCOL* interfaces: one with the just the *EFI_EXT_SCSI_PASS_THRU_ATTRIBUTES_PHYSICAL* bit set and another with just the *EFI_EXT_SCSI_PASS_THRU_ATTRIBUTES_LOGICAL* bit set. One interface can be used to access the physical devices attached to the RAID controller, and the other can be used to access the logical devices attached to the RAID controller for its current configuration.

Drivers for RAID controllers that do not allow access to the physical devices will produce one *EFI_EXT_SCSI_PASS_THROUGH_PROTOCOL* interface with just the *EFI_EXT_SCSI_PASS_THRU_LOGICAL* bit set. The interface for logical devices can also be used by a file system driver to mount the RAID volumes. An *EFI_EXT_SCSI_PASS_THRU_PROTOCOL* with neither *EFI_EXT_SCSI_PASS_THRU_ATTRIBUTES_LOGICAL* nor *EFI_EXT_SCSI_PASS_THRU_ATTRIBUTES_PHYSICAL* set is an illegal configuration.

The Attributes field also contains the *EFI_EXT_SCSI_PASS_THRU_ATTRIBUTES_NONBLOCKIO* bit. All *EFI_EXT_SCSI_PASS_THRU_PROTOCOL* interfaces must support blocking I/O. If this bit is set, then the interface support both blocking I/O and nonblocking I/O.

Each *EFI_EXT_SCSI_PASS_THRU_PROTOCOL* instance must have an associated device path. Typically this will have an ACPI device path node and a PCI device path node, although variation will exist. For a SCSI controller that supports only one channel per PCI bus/device/function, it is recommended, but not required, that an additional Controller device path node (for controller 0) be appended to the device path.

For a SCSI controller that supports multiple channels per PCI bus/device/function, it is required that a Controller device path node be appended for each channel.

Additional information about the SCSI channel can be obtained from protocols attached to the same handle as the *EFI_EXT_SCSI_PASS_THRU_PROTOCOL* , or one of its parent handles. This would include the device I/O abstraction used to access the internal registers and functions of the SCSI controller.

15.7.2 EFI_EXT_SCSI_PASS_THRU_PROTOCOL.PassThru()

Summary

Sends a SCSI Request Packet to a SCSI device that is attached to the SCSI channel. This function supports both blocking I/O and nonblocking I/O. The blocking I/O functionality is required, and the nonblocking I/O functionality is optional.

Prototype

```
typedef
EFI_STATUS
  (EFIAPI *EFI_EXT_SCSI_PASS_THRU_PASSTHRU) (
    IN EFI_EXT_SCSI_PASS_THRU_PROTOCOL                  *This,
    IN UINT8                                            *Target,
    IN UINT64                                           Lun,
    IN OUT EFI_EXT_SCSI_PASS_THRU_SCSI_REQUEST_PACKET  *Packet,
    IN EFI_EVENT                                        Event OPTIONAL
    );
```

Parameters

This

A pointer to the *EFI_EXT_SCSI_PASS_THRU_PROTOCOL* instance. Type *EFI_EXT_SCSI_PASS_THRU_PROTOCOL* is defined in *Extended SCSI Pass Thru Protocol* .

Target

The Target is an array of size *TARGET_MAX_BYTES* and it represents the id of the SCSI device to send the SCSI Request Packet. Each transport driver may chose to utilize a subset of this size to suit the needs of transport target representation. For example, a Fibre Channel driver may use only 8 bytes (WWN) to represent an FC target.

Lun

The LUN of the SCSI device to send the SCSI Request Packet.

Packet

A pointer to the SCSI Request Packet to send to the SCSI device specified by *Target* and *Lun* . See “Related Definitions” below for a description of *EFI_EXT_SCSI_PASS_THRU_SCSI_REQUEST_PACKET* .

Event

If nonblocking I/O is not supported then *Event* is ignored, and blocking I/O is performed. If *Event* is *NULL* , then blocking I/O is performed. If *Event* is not *NULL* and non blocking I/O is supported, then nonblocking I/O is performed, and *Event* will be signaled when the SCSI Request Packet completes.

Related Definitions

```
typedef struct {
  UINT64       Timeout;
  VOID         *InDataBuffer;
  VOID         *OutDataBuffer;
  VOID         *SenseData;
  VOID         *Cdb;
  UINT32       InTransferLength;
  UINT32       OutTransferLength;
  UINT8        CdbLength;
  UINT8        DataDirection;
  UINT8        HostAdapterStatus;
  UINT8        TargetStatus;
  UINT8        SenseDataLength;
} EFI_EXT_SCSI_PASS_THRU_SCSI_REQUEST_PACKET;
```

Timeout

The timeout, in 100 ns units, to use for the execution of this SCSI Request Packet. A *Timeout* value of 0 means that this function will wait indefinitely for the SCSI Request Packet to execute. If *Timeout* is greater than zero, then this function will return *EFI_TIMEOUT* if the time required to execute the SCSI Request Packet is greater than *Timeout* .

InDataBuffer

A pointer to the data buffer to transfer between the SCSI controller and the SCSI device for read and bidirectional commands. For all write and non data commands where *InTransferLength* is 0 this field is optional and may be *NULL* . If this field is not *NULL* , then it must be aligned on the boundary specified by the *IoAlign* field in the *EFI_EXT_SCSI_PASS_THRU_MODE* structure.

OutDataBuffer

A pointer to the data buffer to transfer between the SCSI controller and the SCSI device for write or bidirectional commands. For all read and non data commands where *OutTransferLength* is 0 this field is optional and may be *NULL* . If this field is not *NULL* , then it must be aligned on the boundary specified by the *IoAlign* field in the *EFI_EXT_SCSI_PASS_THRU_MODE* structure.

SenseData

A pointer to the sense data that was generated by the execution of the SCSI Request Packet. If *SenseDataLength* is 0, then this field is optional and may be *NULL* . It is strongly recommended that a sense data buffer of at least 252 bytes be provided to guarantee the entire sense data buffer generated from the execution of the SCSI Request Packet can be returned. If this field is not *NULL* , then it must be aligned to the boundary specified in the *IoAlign* field in the *EFI_EXT_SCSI_PASS_THRU_MODE* structure.

Cdb

A pointer to buffer that contains the Command Data Block to send to the SCSI device specified by *Target* and *Lun* .

InTransferLength

On Input, the size, in bytes, of *InDataBuffer* . On output, the number of bytes transferred between the SCSI controller and the SCSI device. If *InTransferLength* is larger than the SCSI controller can handle, no data will be transferred, *InTransferLength* will be updated to contain the number of bytes that the SCSI controller is able to transfer, and *EFI_BAD_BUFFER_SIZE* will be returned.

OutTransferLength

On Input, the size, in bytes of *OutDataBuffer* . On Output, the Number of bytes transferred between SCSI Controller and the SCSI device. If *OutTransferLength* is larger than the SCSI controller can handle, no data will be transferred, *OutTransferLength* will be updated to contain the number of bytes that the SCSI controller is able to transfer, and *EFI_BAD_BUFFER_SIZE* will be returned.

CdbLength

The length, in bytes, of the buffer *Cdb* . The standard values are 6, 10, 12, and 16, but other values are possible if a variable length *CDB* is used.

DataDirection

The direction of the data transfer. 0 for reads, 1 for writes. A value of 2 is Reserved for Bi-Directional SCSI commands. For example XDREADWRITE. All other values are reserved, and must not be used.

HostAdapterStatus

The status of the host adapter specified by *This* when the SCSI Request Packet was executed on the target device. See the possible values listed below. If bit 7 of this field is set, then *HostAdapterStatus* is a vendor defined error code.

TargetStatus

The status returned by the device specified by *Target* and *Lun* when the SCSI Request Packet was executed. See the possible values listed below.

SenseDataLength

On input, the length in bytes of the *SenseData* buffer. On output, the number of bytes written to the *SenseData* buffer.

```
//
// DataDirection
//
#define EFI_EXT_SCSI_DATA_DIRECTION_READ             0
#define EFI_EXT_SCSI_DATA_DIRECTION_WRITE            1
#define EFI_EXT_SCSI_DATA_DIRECTION_BIDIRECTIONAL    2
//
// HostAdapterStatus
//

#define EFI_EXT_SCSI_STATUS_TARGET_TASK_ABORTED             0x40
```

Description

The *EFI_EXT_SCSI_PASS_THRU_PROTOCOL.PassThru()* function sends the SCSI Request Packet specified by *Packet* to the SCSI device specified by *Target* and *Lun* . If the driver supports nonblocking I/O and *Event* is not *NULL,* then the driver will return immediately after the command is sent to the selected device, and will later signal *Event* when the command has completed.

If the driver supports nonblocking I/O and *Event* is NULL, then the driver will send the command to the selected device and block until it is complete.

If the driver does not support nonblocking I/O, then the *Event* parameter is ignored, and the driver will send the command to the selected device and block until it is complete.

If *Packet* is successfully sent to the SCSI device, then EFI_SUCCESS is returned.

If *Packet* cannot be sent because there are too many packets already queued up, then EFI_NOT_READY is returned. The caller may retry *Packet* at a later time.

If a device error occurs while sending the *Packet* , then EFI_DEVICE_ERROR is returned.

If a timeout occurs during the execution of *Packet* , then EFI_TIMEOUT is returned.

If a device is not present but the target/LUN address in the packet are valid, then EFI_TIMEOUT is returned, and HostStatus is set to *EFI_EXT_SCSI_STATUS_HOST_ADAPTER_TIMEOUT_COMMAND* .

If *Target* or *Lun* are not in a valid range for the SCSI channel, then *EFI_INVALID_PARAMETER* is returned. If *InDataBuffer, OutDataBuffer* or *SenseData* do not meet the alignment requirement specified by the *IoAlign* field of the *EFI_EXT_SCSI_PASS_THRU_MODE* structure, then *EFI_INVALID_PARAMETER* is returned. If any of the other fields of *Packet* are invalid, then *EFI_INVALID_PARAMETER* is returned.

If the data buffer described by *InDataBuffer* and *InTransferLength* is too big to be transferred in a single command, then no data is transferred and *EFI_BAD_BUFFER_SIZE* is returned. The number of bytes that can be transferred in a single command are returned in *InTransferLength* .

If the data buffer described by *OutDataBuffer* and *OutTransferLength* is too big to be transferred in a single command, then no data is transferred and *EFI_BAD_BUFFER_SIZE* is returned. The number of bytes that can be transferred in a single command are returned in *OutTransferLength* .

If the command described in *Packet* is not supported by the host adapter, then *EFI_UNSUPPORTED* is returned.

If *EFI_SUCCESS, EFI_BAD_BUFFER_SIZE, EFI_DEVICE_ERROR* , or *EFI_TIMEOUT* is returned, then the caller must examine the status fields in *Packet* in the following precedence order: *HostAdapterStatus* followed by *TargetStatus* followed by *SenseDataLength* , followed by *SenseData* .

If nonblocking I/O is being used, then the status fields in *Packet* will not be valid until the *Event* associated with *Packet* is signaled.

If *EFI_NOT_READY, EFI_INVALID_PARAMETER* or *EFI_UNSUPPORTED* is returned, then *Packet* was never sent, so the status fields in *Packet* are not valid. If nonblocking I/O is being used, the *Event* associated with *Packet* will not be signaled.

Note: *Some examples of SCSI read commands are READ, INQUIRY, and MODE_SENSE.*

Note: *Some examples of SCSI write commands are WRITE and MODE_SELECT.*

Note: *An example of a SCSI non data command is TEST_UNIT_READY.*

Status Codes Returned

EFI_SUCCESS	The SCSI Request Packet was sent by the host. For bi-directional commands, *InTransferLength* bytes were transferred from *InDataBuffer* . For write and bi-directional commands, *OutTransferLength* bytes were transferred by *OutDataBuffer.* See *HostAdapterStatus, TargetStatus, SenseDataLength,* and *SenseData* in that order for additional status information.
EFI_BAD_BUFFER_SIZE	The SCSI Request Packet was not executed. The number of bytes that could be transferred is returned in *InTransferLength.* For write and bi-directional commands, *OutTransferLength* bytes were transferred by *OutDataBuffer.* See *HostAdapterStatus, TargetStatus,* and in that order for additional status information.
EFI_NOT_READY	The SCSI Request Packet could not be sent because there are too many SCSI Request Packets already queued. The caller may retry again later.
EFI_DEVICE_ERROR	A device error occurred while attempting to send the SCSI Request Packet. See *HostAdapterStatus, TargetStatus, SenseDataLength,* and *SenseData* in that order for additional status information.
EFI_INVALID_PARAMETER	*Target, Lun,* or the contents of *ScsiRequestPacket* are invalid. The SCSI Request Packet was not sent, so no additional status information is available.
EFI_UNSUPPORTED	The command described by the SCSI Request Packet is not supported by the host adapter. This includes the case of Bi-directional SCSI commands not supported by the implementation. The SCSI Request Packet was not sent, so no additional status information is available.
EFI_TIMEOUT	A timeout occurred while waiting for the SCSI Request Packet to execute. See *HostAdapterStatus, TargetStatus, SenseDataLength,* and *SenseData* in that order for additional status information.

15.7.3 EFI_EXT_SCSI_PASS_THRU_PROTOCOL.GetNextTargetLun()

Summary

Used to retrieve the list of legal Target IDs and LUNs for SCSI devices on a SCSI channel. These can either be the list SCSI devices that are actually present on the SCSI channel, or the list of legal Target Ids and LUNs for the SCSI channel. Regardless, the caller of this function must probe the Target ID and LUN returned to see if a SCSI device is actually present at that location on the SCSI channel.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_EXT_SCSI_PASS_THRU_GET_NEXT_TARGET_LUN) (
  IN EFI_EXT_SCSI_PASS_THRU_PROTOCOL         *This,
  IN OUT UINT8                               **Target,
  IN OUT UINT64                              *Lun
  );
```

Parameters

This

A pointer to the *EFI_EXT_SCSI_PASS_THRU_PROTOCOL* instance. Type *EFI_EXT_SCSI_PASS_THRU_PROTOCOL* is defined in *Extended SCSI Pass Thru Protocol* .

Target

On input, a pointer to a legal Target ID (an array of size *TARGET_MAX_BYTES)* for a SCSI device present on the SCSI channel. On output, a pointer to the next legal Target ID (an array of *TARGET_MAX_BYTES*) of a SCSI device on a SCSI channel. An input value of *0xFF* 's (all bytes in the array are *0xFF*) in the Target array retrieves the first legal Target ID for a SCSI device present on a SCSI channel.

Lun

On input, a pointer to the LUN of a SCSI device present on the SCSI channel. On output, a pointer to the LUN of the next SCSI device ID on a SCSI channel.

Description

The *EFI_EXT_SCSI_PASS_THRU_PROTOCOL.GetNextTargetLun()* function retrieves a list of legal Target ID and LUN of a SCSI channel. If on input a *Target* is specified by all *0xFF* in the Target array, then the first legal Target ID and LUN for a SCSI device on a SCSI channel is returned in *Target* and *Lun,* and *EFI_SUCCESS* is returned.

If *Target* and *Lun* is a Target ID and LUN value that was returned on a previous call to *GetNextTargetLun()* , then the next legal Target ID and LUN for a SCSI device on the SCSI channel is returned in *Target* and *Lun* , and *EFI_SUCCESS* is returned.

If *Target array* is not all *0xFF's* and *Target* and *Lun* were not returned on a previous call to *GetNextTargetLun()* , then *EFI_INVALID_PARAMETER* is returned.

If *Target* and *Lun* are the Target ID and LUN of the last SCSI device on the SCSI channel, then *EFI_NOT_FOUND* is returned.

Status Codes Returned

EFI_SUCCESS	The Target ID and LUN of the next SCSI device on the SCSI channel was returned in *Target* and *Lun* .
EFI_NOT_FOUND	There are no more SCSI devices on this SCSI channel.
EFI_INVALID_PARAMETER	*Target array* is not all *0xFF* 's, and *Target* and *Lun* were not returned on a previous call to *GetNextTargetLun()* .

15.7.4 EFI_EXT_SCSI_PASS_THRU_PROTOCOL.BuildDevicePath()

Summary

Used to allocate and build a device path node for a SCSI device on a SCSI channel.

Prototype

```
typedef
  EFI_STATUS
    (EFIAPI *EFI_EXT_SCSI_PASS_THRU_BUILD_DEVICE_PATH) (
      IN EFI_EXT_SCSI_PASS_THRU_PROTOCOL                  *This,
      IN UINT8                                            *Target,
      IN UINT64                                           Lun
      OUT EFI_DEVICE_PATH_PROTOCOL                        **DevicePath
      );
```

Parameters

This

A pointer to the *EFI_EXT_SCSI_PASS_THRU_PROTOCOL* instance. Type *EFI_EXT_SCSI_PASS_THRU_PROTOCOL* is defined in *Extended SCSI Pass Thru Protocol* .

Target

The Target is an array of size *TARGET_MAX_BYTES* and it specifies the Target ID of the SCSI device for which a device path node is to be allocated and built. Transport drivers may chose to utilize a subset of this size to suit the representation of targets. For example, a Fibre Channel driver may use only 8 bytes (WWN) in the array to represent a FC target.

Lun

The LUN of the SCSI device for which a device path node is to be allocated and built.

DevicePath

A pointer to a single device path node that describes the SCSI device specified by *Target* and *Lun*. This function is responsible for allocating the buffer *DevicePath* with the boot service *AllocatePool()*. It is the caller's responsibility to free *DevicePath* when the caller is finished with *DevicePath* .

Description

The *EFI_EXT_SCSI_PASS_THRU_PROTOCOL.BuildDevicePath()* function allocates and builds a single device path node for the SCSI device specified by *Target* and *Lun* . If the SCSI device specified by *Target* and *Lun* are not present on the SCSI channel, then *EFI_NOT_FOUND* is returned. If *DevicePath* is *NULL* , then *EFI_INVALID_PARAMETER* is returned. If there are not enough resources to allocate the device path node, then *EFI_OUT_OF_RESOURCES* is returned. Otherwise, *DevicePath* is allocated with the boot service *AllocatePool()* , the contents of *DevicePath* are initialized to describe the SCSI device specified by *Target* and *Lun* , and *EFI_SUCCESS* is returned.

Status Codes Returned

EFI_SUCCESS	The device path node that describes the SCSI device specified by *Target* and *Lun* was allocated and returned in *DevicePath* .
EFI_NOT_FOUND	The SCSI devices specified by *Target* and *Lun* does not exist on the SCSI channel.
EFI_INVALID_PARAMETER	*DevicePath* is *NULL* .
EFI_OUT_OF_RESOURCES	There are not enough resources to allocate DevicePath.

15.7.5 EFI_EXT_SCSI_PASS_THRU_PROTOCOL.GetTargetLun()

Summary

Used to translate a device path node to a Target ID and LUN.

Prototype

```
typedef
EFI_STATUS
  (EFIAPI *EFI_EXT_SCSI_PASS_THRU_GET_TARGET_LUN) (
    IN EFI_EXT_SCSI_PASS_THRU_PROTOCOL          *This,
    IN EFI_DEVICE_PATH_PROTOCOL                 *DevicePath
    OUT UINT8                                   **Target,
    OUT UINT64                                  *Lun
    );
```

Parameters

This
A pointer to the *EFI_EXT_SCSI_PASS_THRU_PROTOCOL* instance. Type *EFI_EXT_SCSI_PASS_THRU_PROTOCOL* is defined in *Extended SCSI Pass Thru Protocol* .

DevicePath
A pointer to the device path node that describes a SCSI device on the SCSI channel.

Target
A pointer to the Target Array which represents the ID of a SCSI device on the SCSI channel.

Lun
A pointer to the LUN of a SCSI device on the SCSI channel.

Description

The *EFI_EXT_SCSI_PASS_THRU_PROTOCOL.GetTargetLun()* function determines the Target ID and LUN associated with the SCSI device described by *DevicePath* . If *DevicePath* is a device path node type that the SCSI Pass Thru driver supports, then the SCSI Pass Thru driver will attempt to translate the contents *DevicePath* into a Target ID and LUN. If this translation is successful, then that Target ID and LUN are returned in *Target* and *Lun* , and *EFI_SUCCESS* is returned.

If *DevicePath* , *Target* , or *Lun* are *NULL* , then *EFI_INVALID_PARAMETER* is returned.

If *DevicePath* is not a device path node type that the SCSI Pass Thru driver supports, then *EFI_UNSUPPORTED* is returned.

If *DevicePath* is a device path node type that the SCSI Pass Thru driver supports, but there is not a valid translation from *DevicePath* to a Target ID and LUN, then *EFI_NOT_FOUND* is returned.

Status Codes Returned

EFI_SUCCESS	*DevicePath* was successfully translated to a Target ID and LUN, and they were returned in Target and Lun.
EFI_INVALID_PARAMETER	*DevicePath* is *NULL* .
EFI_INVALID_PARAMETER	*Target* is *NULL*
EFI_INVALID_PARAMETER	*Lun* is *NULL*
EFI_UNSUPPORTED	This driver does not support the device path node type in *DevicePath* .

continues on next page

Table 15.14 – continued from previous page

EFI_NOT_FOUND	A valid translation from *DevicePath* to a Target ID and LUN does not exist.

15.7.6 EFI_EXT_SCSI_PASS_THRU_PROTOCOL.ResetChannel()

Summary

Resets a SCSI channel. This operation resets all the SCSI devices connected to the SCSI channel.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_EXT_SCSI_PASS_THRU_RESET_CHANNEL) (
  IN EFI_EXT_SCSI_PASS_THRU_PROTOCOL            *This
  );
```

Parameters

This

A pointer to the *EFI_EXT_SCSI_PASS_THRU_PROTOCOL* instance. Type *EFI_EXT_SCSI_PASS_THRU_PROTOCOL* is defined in *Extended SCSI Pass Thru Protocol* .

Description

The *EFI_EXT_SCSI_PASS_THRU_PROTOCOL.ResetChannel()* function resets a SCSI channel. This operation resets all the SCSI devices connected to the SCSI channel. If this SCSI channel does not support a reset operation, then *EFI_UNSUPPORTED* is returned.

If a device error occurs while executing that channel reset operation, then *EFI_DEVICE_ERROR* is returned.

If a timeout occurs during the execution of the channel reset operation, then *EFI_TIMEOUT* is returned. If the channel reset operation is completed, then *EFI_SUCCESS* is returned.

Status Codes Returned

EFI_SUCCESS	The SCSI channel was reset.
EFI_UNSUPPORTED	The SCSI channel does not support a channel reset operation.
EFI_DEVICE_ERROR	A device error occurred while attempting to reset the SCSI channel.
EFI_TIMEOUT	A timeout occurred while attempting to reset the SCSI channel.

15.7.7 EFI_EXT_SCSI_PASS_THRU_PROTOCOL.ResetTargetLun()

Summary

Resets a SCSI logical unit that is connected to a SCSI channel.

Prototype

```
typedef
EFI_STATUS
  (EFIAPI *EFI_EXT_SCSI_PASS_THRU_RESET_TARGET_LUN) (
  IN EFI_EXT_SCSI_PASS_THRU_PROTOCOL         *This,
    IN UINT8                                 *Target,
    IN UINT64                                Lun
    );
```

Parameters

This

A pointer to the *EFI_EXT_SCSI_PASS_THRU_PROTOCOL* instance. Type *EFI_EXT_SCSI_PASS_THRU_PROTOCOL* is defined in *Extended SCSI Pass Thru Protocol* .

Target

The Target is an array of size *TARGET_MAX_BYTE* and it represents the target port ID of the SCSI device containing the SCSI logical unit to reset. Transport drivers may chose to utilize a subset of this array to suit the representation of their targets. For example a Fibre Channel driver may use only 8 bytes in the array (WWN) to represent a FC target.

Lun

The LUN of the SCSI device to reset.

Description

The *EFI_EXT_SCSI_PASS_THRU_PROTOCOL.ResetTargetLun()* function resets the SCSI logical unit specified by *Target* and *Lun* . If this SCSI channel does not support a target reset operation, then *EFI_UNSUPPORTED* is returned.

If *Target* or *Lun* are not in a valid range for this SCSI channel, then *EFI_INVALID_PARAMETER* is returned.

If a device error occurs while executing that logical unit reset operation, then *EFI_DEVICE_ERROR* is returned.

If a timeout occurs during the execution of the logical unit reset operation, then *EFI_TIMEOUT* is returned.

If the logical unit reset operation is completed, then *EFI_SUCCESS* is returned.

Status Codes Returned

EFI_SUCCESS	The SCSI device specified by *Target* and *Lun* was reset
EFI_UNSUPPORTED	The SCSI channel does not support a target reset operation.
EFI_INVALID_PARAMETER	*Target* or *Lun* are invalid.
EFI_DEVICE_ERROR	A device error occurred while attempting to reset the SCSI device specified by *Target* and *Lun* .
EFI_TIMEOUT	A timeout occurred while attempting to reset the SCSI device specified by *Target* and *Lun* .

15.7.8 EFI_EXT_SCSI_PASS_THRU_PROTOCOL.GetNextTarget()

Summary

Used to retrieve the list of legal Target IDs for SCSI devices on a SCSI channel. These can either be the list SCSI devices that are actually present on the SCSI channel, or the list of legal Target IDs for the SCSI channel. Regardless, the caller of this function must probe the Target ID returned to see if a SCSI device is actually present at that location on the SCSI channel.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_EXT_SCSI_PASS_THRU_GET_NEXT_TARGET) (
   IN EFI_EXT_SCSI_PASS_THRU_PROTOCOL              *This,
   IN OUT UINT8                                    **Target,
   );
```

Parameters

This

A pointer to the *EFI_EXT_SCSI_PASS_THRU_PROTOCOL* instance. Type *EFI_EXT_SCSI_PASS_THRU_PROTOCOL* is defined in *Extended SCSI Pass Thru Protocol* .

Target

On input, a pointer to the Target ID (an array of size *TARGET_MAX_BYTES*) of a SCSI device present on the SCSI channel. On output, a pointer to the Target ID (an array of *TARGET_MAX_BYTES*) of the next SCSI device present on a SCSI channel. An input value of *0xFF* 's (all bytes in the array are *0xFF*) in the Target array retrieves the Target ID of the first SCSI device present on a SCSI channel.

Description

The *EFI_EXT_SCSI_PASS_THRU_PROTOCOL.GetNextTarget()* function retrieves the Target ID of a SCSI device present on a SCSI channel. If on input a *Target* is specified by all 0xF in the Target array, then the Target ID of the first SCSI device is returned in *Target* and *EFI_SUCCESS* is returned.

If *Target* is a Target ID value that was returned on a previous call to *GetNextTarget()* , then the Target ID of the next SCSI device on the SCSI channel is returned in *Target* , and *EFI_SUCCESS* is returned.

If *Target* array is not all *0xFF's* and *Target* were not returned on a previous call to *GetNextTarget()* , then *EFI_INVALID_PARAMETER* is returned.

If *Target* is the Target ID of the last SCSI device on the SCSI channel, then *EFI_NOT_FOUND* is returned.

Status Codes Returned

EFI_SUCCESS	The Target ID of the next SCSI device on the SCSI channel was returned in *Target* .
EFI_NOT_FOUND	There are no more SCSI devices on this SCSI channel.
EFI_INVALID_PARAMETER	*Target array* is not all *0xFF's* , and *Target* were not returned on a previous call to *GetNextTarget()*.

CHAPTER

SIXTEEN

PROTOCOLS — ISCSI BOOT

16.1 Overview

The iSCSI protocol defines a transport for SCSI data over TCP/IP. It also provides an interoperable solution that takes advantage of existing internet infrastructure, management facilities, and addresses distance limitations. The iSCSI protocol specification was developed by the Internet Engineering Task Force (IETF) and is SCSI Architecture Model-2 (SAM-2) compliant. iSCSI encapsulates block-oriented SCSI commands into iSCSI Protocol Data Units (PDU) that traverse the network over TCP/IP. iSCSI defines a Session, the initiator and target nexus (I-T nexus), which could be a bundle of one or more TCP connections.

Similar to other existing mass storage protocols like Fibre Channel and parallel SCSI, boot over iSCSI is an important functionality. This document will attempt to capture the various cases for iSCSI boot and common up with generic EFI protocol changes to address them.

16.1.1 iSCSI UEFI Driver Layering

iSCSI UEFI Drivers may exist in two different forms:

- **iSCSI UEFI Driver on a NIC:**
  The driver will be layered on top of the networking layers. It will use the DHCP, IP, and TCP and packet level interface protocols of the UEFI networking stack. The driver will use an iSCSI software initiator.
- **iSCSI UEFI Driver on a Host Bus Adapter (HBA)that may use an offloading engine such as TOE (or anyother TCP offload card):**
  The driver will be layered on top of the TOE TCP interfaces. It will use the DHCP, IP, TCP protocols of the TOE. The driver will present itself as a SCSI device driver using interfaces such as *EFI_EXT_SCSI_PASS_THRU_PROTOCOL* .

To help in detecting iSCSI UEFI Drivers and their capabilities, the iSCSI UEFI driver handle must include an instance of the *EFI_ADAPTER_INFORMATION_PROTOCOL* with a *EFI_ADAPTER_INFO_NETWORK_BOOT* structure.

16.2 EFI iSCSI Initiator Name Protocol

This protocol sets and obtains the iSCSI Initiator Name. The iSCSI Initiator Name protocol builds a default iSCSI name. The iSCSI name configures using the programming interfaces defined below. Successive configuration of the iSCSI initiator name overwrites the previously existing name. Once overwritten, the previous name will not be retrievable. Setting an iSCSI name string that is zero length is illegal. The maximum size of the iSCSI Initiator Name is 224 bytes (including the **NULL** terminator).

16.2.1 EFI_ISCSI_INITIATOR_NAME_PROTOCOL

Summary

iSCSI Initiator Name Protocol for setting and obtaining the iSCSI Initiator Name.

GUID

```
#define EFI_ISCSI_INITIATOR_NAME_PROTOCOL_GUID \
  {0x59324945, 0xec44, 0x4c0d, \
    {0xb1, 0xcd, 0x9d, 0xb1, 0x39, 0xdf, 0x07, 0x0c}}
```

Protocol Interface Structure

```
typedef struct _EFI_ISCSI_INITIATOR_NAME_PROTOCOL {
  EFI_ISCSI_INITIATOR_NAME_GET                    Get;
  EFI_ISCSI_INITIATOR_NAME_SET                    Set;
}   EFI_ISCSI_INITIATOR_NAME_PROTOCOL;
```

Parameters

Get
Used to retrieve the iSCSI Initiator Name.

Set
Used to set the iSCSI Initiator Name.

Description

The *EFI_ISCSI_INIT_NAME_PROTOCOL* provides the ability to get and set the iSCSI Initiator Name.

16.2.2 EFI_ISCSI_INITIATOR_NAME_PROTOCOL. Get()

Summary

Retrieves the current set value of iSCSI Initiator Name.

Prototype

```
typedef EFI_STATUS
(EFIAPI *EFI_ISCSI_INITIATOR_NAME_GET) (
  IN EFI_ISCSI_INITIATOR_NAME_PROTOCOL    *This,
  IN OUT UINTN                            *BufferSize,
  OUT VOID                                *Buffer
  );
```

Parameters

This
Pointer to the *EFI_ISCSI_INITIATOR_NAME_PROTOCOL* instance.

BufferSize
Size of the buffer in bytes pointed to by Buffer / Actual size of the variable data buffer.

Buffer
Pointer to the buffer for data to be read. The data is a null-terminated UTF-8 encoded string. The maximum length is 223 characters, including the null-terminator.

Description

This function will retrieve the iSCSI Initiator Name from Non-volatile memory.

Status Codes Returned

EFI_SUCCESS	Data was successfully retrieved into the provided buffer and the *BufferSize* was sufficient to handle the iSCSI initiator name
EFI_BUFFER_TOO_SMALL	*BufferSize* is too small for the result. *BufferSize* will be updated with the size required to complete the request. *Buffer* will not be affected.
EFI_INVALID_PARAMETER	*BufferSize* is **NULL**. *BufferSize* and *Buffer* will not be affected.
EFI_INVALID_PARAMETER	*Buffer* is **NULL**. *BufferSize* and *Buffer* will not be affected.
EFI_DEVICE_ERROR	The iSCSI initiator name could not be retrieved due to a hardware error.

16.2.3 EFI_ISCSI_INITIATOR_NAME_PROTOCOL.Set()

Summary

Sets the iSCSI Initiator Name.

Prototype

```
typedef EFI_STATUS
(EFIAPI *EFI_ISCSI_INITIATOR_NAME_SET) (
  IN EFI_ISCSI_INITIATOR_NAME_PROTOCOL       *This,
  IN OUT UINTN                               *BufferSize,
  IN VOID                                    *Buffer
  );
```

Parameters

This

Pointer to the *EFI_ISCSI_INITIATOR_NAME_PROTOCOL* instance

BufferSize

Size of the buffer in bytes pointed to by Buffer.

Buffer

Pointer to the buffer for data to be written. The data is a null-terminated UTF-8 encoded string. The maximum length is 223 characters, including the null-terminator.

Description

This function will set the iSCSI Initiator Name into Non-volatile memory.

Status Codes Returned

EFI_SUCCESS	Data was successfully stored by the protocol
EFI_UNSUPPORTED	Platform policies do not allow for data to be written
EFI_INVALID_PARAMETER	*BufferSize* exceeds the maximum allowed limit. *BufferSize* will be updated with the maximum size required to complete the request.
EFI_INVALID_PARAMETER	*Buffersize* is **NULL**. *BufferSize* and *Buffer* will not be affected
EFI_INVALID_PARAMETER	*Buffer* is **NULL**. *BufferSize* and *Buffer* will not be affected.

SEVENTEEN

PROTOCOLS — USB SUPPORT

17.1 USB2 Host Controller Protocol

USB2 Host Controller Protocol and *USB Host Controller Protocol Overview* describe the USB2 Host Controller Protocol. This protocol provides an I/O abstraction for a USB2 Host Controller. The USB2 Host Controller is a hardware component that interfaces to a Universal Serial Bus (USB). It moves data between system memory and devices on the USB by processing data structures and generating transactions on the USB. This protocol is used by a USB Bus Driver to perform all data transaction over the Universal Serial Bus. It also provides services to manage the USB root hub that is integrated into the USB Host Controller. USB device drivers do not use this protocol directly. Instead, they use the I/O abstraction produced by the USB Bus Driver. This protocol should only be used by drivers that require direct access to the USB bus.

17.1.1 USB Host Controller Protocol Overview

The USB Host Controller Protocol is used by code, typically USB bus drivers, running in the EFI boot services environment, to perform data transactions over a USB bus. In addition, it provides an abstraction for the root hub of the USB bus.

The interfaces provided in the *EFI_USB2_HC_PROTOCOL* are used to manage data transactions on a USB bus. It also provides control methods for the USB root hub. The *EFI_USB2_HC_PROTOCOL* is designed to support both USB 1.1 and USB 2.0 - compliant host controllers.

The *EFI_USB2_HC_PROTOCOL* abstracts basic functionality that is designed to operate with the EHCI, UHCI and OHCI standards. By using this protocol, a single USB bus driver can be implemented without knowing if the underlying USB host controller conforms to the XHCI, EHCI, OHCI or the UHCI standards.

Each instance of the *EFI_USB2_HC_PROTOCOL* corresponds to a USB host controller in a platform. The protocol is attached to the device handle of a USB host controller that is created by a device driver for the USB host controller's parent bus type. For example, a USB host controller that is implemented as a PCI device would require a PCI device driver to produce an instance of the *EFI_USB2_HC_PROTOCOL*.

17.1.2 EFI_USB2_HC_PROTOCOL

Summary

Provides basic USB host controller management, basic data transactions over USB bus, and USB root hub access.

GUID

```
#define EFI_USB2_HC_PROTOCOL_GUID \
  {0x3e745226,0x9818,0x45b6,\
    {0xa2,0xac,0xd7,0xcd,0x0e,0x8b,0xa2,0xbc}}
```

Protocol Interface Structure

```
typedef struct _EFI_USB2_HC_PROTOCOL {
  EFI_USB2_HC_PROTOCOL_GET_CAPABILITY              GetCapability;
  EFI_USB2_HC_PROTOCOL_RESET                       Reset;
  EFI_USB2_HC_PROTOCOL_GET_STATE                   GetState;
  EFI_USB2_HC_PROTOCOL_SET_STATE                   SetState;
  EFI_USB2_HC_PROTOCOL_CONTROL_TRANSFER            ControlTransfer;
  EFI_USB2_HC_PROTOCOL_BULK_TRANSFER               BulkTransfer;
  EFI_USB2_HC_PROTOCOL_ASYNC_INTERRUPT_TRANSFER    AsyncInterruptTransfer;
  EFI_USB2_HC_PROTOCOL_ASYNC_INTERRUPT_TRANSFER    SyncInterruptTransfer;
  EFI_USB2_HC_PROTOCOL_ISOCHRONOUS_TRANSFER        IsochronousTransfer;
  EFI_USB2_HC_PROTOCOL_ASYNC_ISOCHRONOUS_TRANSFER  AsyncIsochronousTransfer;
  EFI_USB2_HC_PROTOCOL_GET_ROOTHUB_PORT_STATUS     GetRootHubPortStatus;
  EFI_USB2_HC_PROTOCOL_SET_ROOTHUB_PORT_FEATURE    SetRootHubPortFeature;
  EFI_USB2_HC_PROTOCOL_CLEAR_ROOTHUB_PORT_FEATURE  ClearRootHubPortFeature
  UINT16                                           MajorRevision;
  UINT16                                           MinorRevision;
} EFI_USB2_HC_PROTOCOL;
```

Parameters

GetCapability
Retrieves the capabilities of the USB host controller. See the *EFI_USB2_HC_PROTOCOL.GetCapability()* function description.

Reset
Software reset of USB. See the *EFI_USB2_HC_PROTOCOL.Reset()* function description.

GetState
Retrieves the current state of the USB host controller. See the *EFI_USB2_HC_PROTOCOL.GetState()* function description.

SetState
Sets the USB host controller to a specific state. See the *EFI_USB2_HC_PROTOCOL.SetState()* function description.

ControlTransfer
Submits a control transfer to a target USB device. See the *EFI_USB2_HC_PROTOCOL.ControlTransfer()* function description.

BulkTransfer
Submits a bulk transfer to a bulk endpoint of a USB device. See the *EFI_USB2_HC_PROTOCOL.BulkTransfer()* function description.

AsyncInterruptTransfer
Submits an asynchronous interrupt transfer to an interrupt endpoint of a USB device. See the *EFI_USB2_HC_PROTOCOL.AsyncInterruptTransfer()* function description.

SyncInterruptTransfer
Submits a synchronous interrupt transfer to an interrupt endpoint of a USB device. See the *EFI_USB2_HC_PROTOCOL.SyncInterruptTransfer()* function description.

IsochronousTransfer
Submits isochronous transfer to an isochronous endpoint of a USB device. See the *EFI_USB2_HC_PROTOCOL.IsochronousTransfer()* function description.

AsyncIsochronousTransfer
Submits nonblocking USB isochronous transfer. See the *EFI_USB2_HC_PROTOCOL.AsyncIsochronousTransfer()*

function description.

GetRootHubPortStatus
Retrieves the status of the specified root hub port. See the *EFI_USB2_HC_PROTOCOL.GetRootHubPortStatus()* function description.

SetRootHubPortFeature
Sets the feature for the specified root hub port. See the *EFI_USB2_HC_PROTOCOL.SetRootHubPortFeature()* function description.

ClearRootHubPortFeature
Clears the feature for the specified root hub port. See the *EFI_USB2_HC_PROTOCOL.ClearRootHubPortFeature()* function description.

MajorRevision
The major revision number of the USB host controller. The revision information indicates the release of the Universal Serial Bus Specification with which the host controller is compliant.

MinorRevision
The minor revision number of the USB host controller. The revision information indicates the release of the Universal Serial Bus Specification with which the host controller is compliant.

Description

The *EFI_USB2_HC_PROTOCOL* provides USB host controller management, basic data transactions over a USB bus, and USB root hub access. A device driver that wishes to manage a USB bus in a system retrieves the *EFI_USB2_HC_PROTOCOL* instance that is associated with the USB bus to be managed. A device handle for a USB host controller will minimally contain an *EFI Device Path Protocol* instance, and an *EFI_USB2_HC_PROTOCOL* instance.

17.1.3 EFI_USB2_HC_PROTOCOL.GetCapability()

Summary

Retrieves the Host Controller capabilities.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USB2_HC_PROTOCOL_GET_CAPABILITY) (
  IN EFI_USB2_HC_PROTOCOL          *This,
  OUT UINT8                        *MaxSpeed,
  OUT UINT8                        *PortNumber,
  OUT UINT8                        *Is64BitCapable
  );
```

Parameters

This
A pointer to the *EFI_USB2_HC_PROTOCOL* instance. Type EFI_USB2_HC_PROTOCOL is defined in *USB2 Host Controller Protocol* .

MaxSpeed
Host controller data transfer speed; see **Related Definitions** below for a list of supported transfer speed values.

PortNumber
Number of the root hub ports.

Is64BitCapable

TRUE if controller supports 64-bit memory addressing, **FALSE** otherwise.

Related Definitions

```
#define EFI_USB_SPEED_FULL     0x0000
#define EFI_USB_SPEED_LOW      0x0001
#define EFI_USB_SPEED_HIGH     0x0002
#define EFI_USB_SPEED_SUPER    0x0003
```

EFI_USB_SPEED_LOW	Low speed USB device; data bandwidth is up to 1.5 Mb/s. Supported by USB 1.1 OHCI and UHCI host controllers.
EFI_USB_SPEED_FULL	Full speed USB device; data bandwidth is up to 12 Mb/s. Supported by USB 1.1 OHCI and UHCI host controllers.
EFI_USB_SPEED_HIGH	High speed USB device; data bandwidth is up to 480 Mb/s. Supported by USB 2.0 EHCI host controllers.
EFI_USB_SPEED_SUPER	Super speed USB device; data bandwidth is up to 4.8Gbs. Supported by USB 3.0 XHCI host controllers.

Description

This function is used to retrieve the host controller capabilities. *MaxSpeed* indicates the maximum data transfer speed the controller is capable of; this information is needed for the subsequent transfers. *PortNumber* is the number of root hub ports, it is required by the USB bus driver to perform bus enumeration. *Is64BitCapable* indicates that controller is capable of 64-bit memory access so that the host controller software can use memory blocks above 4 GiB for the data transfers.

Status Codes Returned

EFI_SUCCESS	The host controller capabilities were retrieved successfully.
EFI_INVALID_PARAMETER	MaxSpeed or PortNumber or Is64BitCapable is **NULL**.
EFI_DEVICE_ERROR	An error was encountered while attempting to retrieve the capabilities.

17.1.4 EFI_USB2_HC_PROTOCOL.Reset()

Summary

Provides software reset for the USB host controller.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USB2_HC_PROTOCOL_RESET) (
  IN EFI_USB2_HC_PROTOCOL            *This,
  IN UINT16                          Attributes
  );
```

Parameters

This

A pointer to the *EFI_USB2_HC_PROTOCOL* instance. Type EFI_USB2_HC_PROTOCOL is defined in *USB2 Host Controller Protocol* .

Attributes

A bit mask of the reset operation to perform. See **Related Definitions** below for a list of the supported bit mask values.

Related Definitions

```
#define EFI_USB_HC_RESET_GLOBAL                 0x0001
#define EFI_USB_HC_RESET_HOST_CONTROLLER        0x0002
#define EFI_USB_HC_RESET_GLOBAL_WITH_DEBUG      0x0004
#define EFI_USB_HC_RESET_HOST_WITH_DEBUG        0x0008
```

EFI_USB_HC_RESET_GLOBAL

If this bit is set, a global reset signal will be sent to the USB bus. This resets all of the USB bus logic, including the USB host controller hardware and all the devices attached on the USB bus.

EFI_USB_HC_RESET_HOST_CONTROLLER

If this bit is set, the USB host controller hardware will be reset. No reset signal will be sent to the USB bus.

EFI_USB_HC_RESET_GLOBAL_WITH_DEBUG

If this bit is set, then a global reset signal will be sent to the USB bus. This resets all of the USB bus logic, including the USB host controller and all of the devices attached on the USB bus. If this is an XHCI or EHCI controller and the debug port has been configured, then this will still reset the host controller.

EFI_USB_HC_RESET_HOST_WITH_DEBUG

If this bit is set, the USB host controller hardware will be reset. If this is an XHCI or EHCI controller and the debug port has been configured, then this will still reset the host controller.

Description

This function provides a software mechanism to reset a USB host controller. The type of reset is specified by the *Attributes* parameter. If the type of reset specified by *Attributes* is not valid, then *EFI_INVALID_PARAMETER* is returned. If the reset operation is completed, then *EFI_SUCCESS* is returned. If the type of reset specified by *Attributes* is not currently supported by the host controller hardware, *EFI_UNSUPPORTD* is returned. If a device error occurs during the reset operation, then *EFI_DEVICE_ERROR* is returned.

Note: For XHCI or EHCI controllers, the *EFI_USB_HC_RESET_GLOBAL* and *EFI_USB_HC_RESET_HOST_CONTROLLER* types of reset do not actually reset the bus if the debug port has been configured. In these cases, the function will return *EFI_ACCESS_DENIED*.

Status Codes Returned

EFI_SUCCESS	The reset operation succeeded.
EFI_INVALID_PARAMETER	Attributes is not valid.
EFI_UNSUPPORTED	The type of reset specified by Attributes is not currently supported by the host controller hardware.
EFI_ACCESS_DENIED	Reset operation is rejected due to the debug port being configured and active; only *EFI_USB_HC_RESET_GLOBAL_WITH_DEBUG* or *EFI_USB_HC_RESET_HOST_WITH_DEBUG* reset *Attributes* can be used to perform reset operation for this host controller.
EFI_DEVICE_ERROR	An error was encountered while attempting to perform the reset operation.

17.1.5 EFI_USB2_HC_PROTOCOL.GetState()

Summary

Retrieves current state of the USB host controller.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USB2_HC_PROTOCOL_GET_STATE) (
  IN EFI_USB2_HC_PROTOCOL             *This,
  OUT EFI_USB_HC_STATE                *State
  );
```

Parameters

This
A pointer to the *EFI_USB2_HC_PROTOCOL* instance. Type EFI_USB2_HC_PROTOCOL is defined in *USB2 Host Controller Protocol* .

State
A pointer to the *EFI_USB_HC_STATE* data structure that indicates current state of the USB host controller. Type EFI_USB_HC_STATE is defined in **Related Definitions.**

Related Definitions

```
typedef enum {
  EfiUsbHcStateHalt,
  EfiUsbHcStateOperational,
  EfiUsbHcStateSuspend,
  EfiUsbHcStateMaximum
}   EFI_USB_HC_STATE;
```

EfiUsbHcStateHalt
The host controller is in halt state. No USB transactions can occur while in this state. The host controller can enter this state for three reasons:

- After host controller hardware reset.
- Explicitly set by software.
- Triggered by a fatal error such as consistency check failure.

EfiUsbHcStateOperational
The host controller is in an operational state. When in this state, the host controller can execute bus traffic. This state must be explicitly set to enable the USB bus traffic.

EfiUsbHcStateSuspend
The host controller is in the suspend state. No USB transactions can occur while in this state. The host controller enters this state for the following reasons:

- Explicitly set by software.
- Triggered when there is no bus traffic for 3 microseconds.

Description

This function is used to retrieve the USB host controller's current state. The USB Host Controller Protocol publishes three states for USB host controller, as defined in **Related Definitions** below. If *State* is **NULL**, then *EFI_INVALID_PARAMETER* is returned. If a device error occurs while attempting to retrieve the USB host controllers current state, then *EFI_DEVICE_ERROR* is returned. Otherwise, the USB host controller's current state is returned in *State*, and *EFI_SUCCESS* is returned.

Status Codes Returned

EFI_SUCCESS	The state information of the host controller was returned in State.
EFI_INVALID_PARAMETER	State is **NULL**.
EFI_DEVICE_ERROR	An error was encountered while attempting to retrieve the host controller's current state.

17.1.6 EFI_USB2_HC_PROTOCOL.SetState()

Summary

Sets the USB host controller to a specific state.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USB2_HC_PROTOCOL_SET_STATE) (
  IN EFI_USB2_HC_PROTOCOL          *This,
  IN EFI_USB_HC_STATE              State
  );
```

Parameters

This

A pointer to the *EFI_USB2_HC_PROTOCOL* instance. Type EFI_USB2_HC_PROTOCOL is defined in *USB2 Host Controller Protocol* .

State

Indicates the state of the host controller that will be set. See the definition and description of the type EFI_USB_HC_STATE in the *EFI_USB2_HC_PROTOCOL.GetState()* function description.

Description

This function is used to explicitly set a USB host controller's state. There are three states defined for the USB host controller. These are the halt state, the operational state and the suspend state. The Figure below, *Software Triggered State Transitions of a USB Host Controller*, illustrates the possible state transitions:

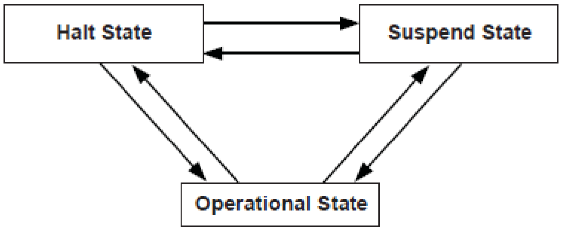

Fig. 17.1: Software Triggered State Transitions of a USB Host Controller

If the state specified by *State* is not valid, then *EFI_INVALID_PARAMETER* is returned. If a device error occurs while attempting to place the USB host controller into the state specified by *State*, then *EFI_DEVICE_ERROR* is returned. If the USB host controller is successfully placed in the state specified by *State*, then *EFI_SUCCESS* is returned.

Status Codes Returned

EFI_SUCCESS	The USB host controller was successfully placed in the state specified by State.
EFI_INVALID_PARAMETER	State is invalid.
EFI_DEVICE_ERROR	Failed to set the state specified by State due to device error.

17.1.7 EFI_USB2_HC_PROTOCOL.ControlTransfer()

Summary

Submits control transfer to a target USB device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USB2_HC_PROTOCOL_CONTROL_TRANSFER) (
  IN EFI_USB2_HC_PROTOCOL                *This,
  IN UINT8                               DeviceAddress,
  IN UINT8                               DeviceSpeed,
  IN UINTN                               MaximumPacketLength,
  IN EFI_USB_DEVICE_REQUEST              *Request,
  IN EFI_USB_DATA_DIRECTION              TransferDirection,
  IN OUT VOID                            *Data OPTIONAL,
  IN OUT UINTN                           *DataLength OPTIONAL,
  IN UINTN                               TimeOut,
  IN EFI_USB2_HC_TRANSACTION_TRANSLATOR  *Translator,
  OUT UINT32                             *TransferResult
  );
```

Related Definitions

```
typedef struct {
  UINT8                    TranslatorHubAddress,
  UINT8                    TranslatorPortNumber
 } EFI_USB2_HC_TRANSACTION_TRANSLATOR;
```

Parameters

This

A pointer to the *EFI_USB2_HC_PROTOCOL* instance. Type EFI_USB2_HC_PROTOCOL is defined in *USB2 Host Controller Protocol* .

DeviceAddress

Represents the address of the target device on the USB, which is assigned during USB enumeration.

DeviceSpeed

Indicates device speed. See **Related Definitions** in GetCapability() for a list of the supported values.

MaximumPacketLength

Indicates the maximum packet size that the default control transfer endpoint is capable of sending or receiving.

Request

A pointer to the USB device request that will be sent to the USB device. Refer to *UsbControlTransfer()* (*USB I/O Protocol*) for the definition of this function type.

TransferDirection

Specifies the data direction for the transfer. There are three values available, EfiUsbDataIn, EfiUsbDataOut and EfiUsbNoData. Refer to *UsbControlTransfer()* (*USB I/O Protocol*) for the definition of this function type.

Data

A pointer to the buffer of data that will be transmitted to USB device or received from USB device.

DataLength

On input, indicates the size, in bytes, of the data buffer specified by Data. On output, indicates the amount of data actually transferred.

Translator

A pointer to the transaction translator data. See "Description" for the detailed information of this data structure.

TimeOut

Indicates the maximum time, in milliseconds, which the transfer is allowed to complete.

TransferResult

A pointer to the detailed result information generated by this control transfer. Refer to *UsbControlTransfer()* (*USB I/O Protocol*) for transfer result types (*EFI_USB_ERR_x*).

Description

This function is used to submit a control transfer to a target USB device specified by *DeviceAddress*. Control transfers are intended to support configuration/command/status type communication flows between host and USB device.

There are three control transfer types according to the data phase. If the *TransferDirection* parameter is *EfiUsbNoData*, *Data* is **NULL**, and *DataLength* is 0, then no data phase is present in the control transfer. If the *TransferDirection* parameter is *EfiUsbDataOut*, then *Data* specifies the data to be transmitted to the device, and *DataLength* specifies the number of bytes to transfer to the device. In this case, there is an OUT DATA stage followed by a SETUP stage. If the *TransferDirection* parameter is *EfiUsbDataIn*, then *Data* specifies the data to be received from the device, and *DataLength* specifies the number of bytes to receive from the device. In this case there is an IN DATA stage followed by a SETUP stage.

Translator is necessary to perform split transactions on low-speed or full-speed devices connected to a high-speed hub. Such transaction require the device connection information: device address and the port number of the hub that device is connected to. This information is passed through the fields of *EFI_USB2_HC_TRANSACTION_TRANSLATOR* structure. See **Related Definitions** for the structure field names. Translator is passed as **NULL** for the USB1.1 host controllers transfers or when the transfer is requested for high-speed device connected to USB2.0 controller.

If the control transfer has completed successfully, then *EFI_SUCCESS* is returned. If the transfer cannot be completed within the timeout specified by *TimeOut*, then *EFI_TIMEOUT* is returned. If an error other than timeout occurs during the USB transfer, then *EFI_DEVICE_ERROR* is returned and the detailed error code will be returned in the *TransferResult* parameter.

EFI_INVALID_PARAMETER is returned if one of the following conditions is satisfied:

- *TransferDirection* is invalid.
- *TransferDirection*, *Data*, and *DataLength* do not match one of the three control transfer types described above.
- *Request* pointer is **NULL**.
- *MaximumPacketLength* is not valid. If *DeviceSpeed* is *EFI_USB_SPEED_LOW*, then *MaximumPacketLength* must be 8. If *DeviceSpeed* is *EFI_USB_SPEED_FULL* or *EFI_USB_SPEED_HIGH*, then *MaximumPacketLength* must be 8, 16, 32, or 64. If *DeviceSpeed* is *EFI_USB_SPEED_SUPER*, then *MaximumPacketLength* must be 512.

- *TransferResult* pointer is **NULL**.
- *Translator* is **NULL** while the requested transfer requires split transaction. The conditions of the split transactions are described above in "Description" section.

Status Codes Returned

EFI_SUCCESS	The control transfer was completed successfully.
EFI_OUT_OF_RESOURCES	The control transfer could not be completed due to a lack of resources.
EFI_INVALID_PARAMETER	Some parameters are invalid. The possible invalid parameters are described in "Description" above.
EFI_TIMEOUT	The control transfer failed due to timeout.
EFI_DEVICE_ERROR	The control transfer failed due to host controller or device error. Caller should check TransferResult for detailed error information.

17.1.8 EFI_USB2_HC_PROTOCOL.BulkTransfer()

Summary

Submits bulk transfer to a bulk endpoint of a USB device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USB2_HC_PROTOCOL_BULK_TRANSFER) (
  IN EFI_USB2_HC_PROTOCOL                *This,
  IN UINT8                               DeviceAddress,
  IN UINT8                               EndPointAddress,
  IN UINT8                               DeviceSpeed,
  IN UINTN                               MaximumPacketLength,
  IN UINT8                               DataBuffersNumber,
  IN OUT VOID                            *Data[EFI_USB_MAX_BULK_BUFFER_NUM],
  IN OUT UINTN                           *DataLength,
  IN OUT UINT8                           *DataToggle,
  IN UINTN                               TimeOut,
  IN EFI_USB2_HC_TRANSACTION_TRANSLATOR *Translator,
  OUT UINT32                             *TransferResult
  );
```

Parameters

This

A pointer to the *EFI_USB2_HC_PROTOCOL* instance. Type EFI_USB2_HC_PROTOCOL is defined in *USB2 Host Controller Protocol* .

DeviceAddress

Represents the address of the target device on the USB, which is assigned during USB enumeration.

EndPointAddress

The combination of an endpoint number and an endpoint direction of the target USB device. Each endpoint address supports data transfer in one direction except the control endpoint (whose default endpoint address is 0). It is the caller's responsibility to make sure that the *EndPointAddress* represents a bulk endpoint.

DeviceSpeed

Indicates device speed. The supported values are *EFI_USB_SPEED_FULL,EFI_USB_SPEED_HIGH* or *EFI_USB_SPEED_SUPER.*.

MaximumPacketLength

Indicates the maximum packet size the target endpoint is capable of sending or receiving.

DataBuffersNumber

Number of data buffers prepared for the transfer.

Data

Array of pointers to the buffers of data that will be transmitted to USB device or received from USB device.

DataLength

When input, indicates the size, in bytes, of the data buffers specified by *Data*. When output, indicates the actually transferred data size.

DataToggle

A pointer to the data toggle value. On input, it indicates the initial data toggle value the bulk transfer should adopt; on output, it is updated to indicate the data toggle value of the subsequent bulk transfer.

Translator

A pointer to the transaction translator data. See ControlTransfer() "Description" for the detailed information of this data structure.

TimeOut

Indicates the maximum time, in milliseconds, which the transfer is allowed to complete.

TransferResult

A pointer to the detailed result information of the bulk transfer. Refer to *UsbControlTransfer()* in *USB I/O Protocol* for transfer result types (*EFI_USB_ERR_x*).

Description

This function is used to submit bulk transfer to a target endpoint of a USB device. The target endpoint is specified by *DeviceAddress* and *EndpointAddress*. Bulk transfers are designed to support devices that need to communicate relatively large amounts of data at highly variable times where the transfer can use any available bandwidth. Bulk transfers can be used only by full-speed and high-speed devices.

High-speed bulk transfers can be performed using multiple data buffers. The number of buffers that are actually prepared for the transfer is specified by *DataBuffersNumber*. For full-speed bulk transfers this value is ignored.

Data represents a list of pointers to the data buffers. For full-speed bulk transfers only the data pointed by *Data[0]* shall be used. For high-speed transfers depending on *DataLength* there several data buffers can be used. The total number of buffers must not exceed *EFI_USB_MAX_BULK_BUFFER_NUM*. See **Related Definitions** for the *EFI_USB_MAX_BULK_BUFFER_NUM* value.

The data transfer direction is determined by the endpoint direction that is encoded in the *EndPointAddress* parameter. Refer to USB Specification, Revision 2.0 on the Endpoint Address encoding.

The *DataToggle* parameter is used to track target endpoint's data sequence toggle bits. The USB provides a mechanism to guarantee data packet synchronization between data transmitter and receiver across multiple transactions. The data packet synchronization is achieved with the data sequence toggle bits and the DATA0/DATA1 PIDs. A bulk endpoint's toggle sequence is initialized to DATA0 when the endpoint experiences a configuration event. It toggles between DATA0 and DATA1 in each successive data transfer. It is host's responsibility to track the bulk endpoint's data toggle sequence and set the correct value for each data packet. The input *DataToggle* value points to the data toggle value for the first data packet of this bulk transfer; the output *DataToggle* value points to the data toggle value for the last successfully transferred data packet of this bulk transfer. The caller should record the data toggle value for use in subsequent bulk transfers to the same endpoint.

If the bulk transfer is successful, then *EFI_SUCCESS* is returned. If USB transfer cannot be completed within the timeout specified by *Timeout*, then *EFI_TIMEOUT* is returned. If an error other than timeout occurs during the USB transfer, then *EFI_DEVICE_ERROR* is returned and the detailed status code is returned in *TransferResult*.

EFI_INVALID_PARAMETER is returned if one of the following conditions is satisfied:

- *Data* is **NULL**.
- *DataLength* is 0.
- *DeviceSpeed* is not valid; the legal values are *EFI_USB_SPEED_FULL*, *EFI_USB_SPEED_HIGH,* or *EFI_USB_SPEED_SUPER.*
- *MaximumPacketLength* is not valid. The legal value of this parameter is 64 or less for full-speed, 512 or less for high-speed, and 1024 or less for super-speed transactions.
- *DataToggle* points to a value other than 0 and 1.
- *TransferResult* is **NULL**.

Status Codes Returned

EFI_SUCCESS	The bulk transfer was completed successfully.
EFI_OUT_OF_RESOURCES	The bulk transfer could not be submitted due to lack of resource.
EFI_INVALID_PARAMETER	Some parameters are invalid. The possible invalid parameters are described in “Description” above.
EFI_TIMEOUT	The bulk transfer failed due to timeout.
EFI_DEVICE_ERROR	The bulk transfer failed due to host controller or device error. Caller should check TransferResult for detailed error information.

17.1.9 EFI_USB2_HC_PROTOCOL.AsyncInterruptTransfer()

Summary

Submits an asynchronous interrupt transfer to an interrupt endpoint of a USB device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USB2_HC_PROTOCOL_ASYNC_INTERRUPT_TRANSFER) (
  IN EFI_USB2_HC_PROTOCOL               *This,
  IN UINT8                              DeviceAddress,
  IN UINT8                              EndPointAddress,
  IN UINT8                              DeviceSpeed,
  IN UINTN                              MaximumPacketLength,
  IN BOOLEAN                            IsNewTransfer,
  IN OUT UINT8                          *DataToggle,
  IN UINTN                              PollingInterval OPTIONAL,
  IN UINTN                              DataLength OPTIONAL,
  IN EFI_USB2_HC_TRANSACTION_TRANSLATOR  *Translator OPTIONAL,
  IN EFI_ASYNC_USB_TRANSFER_CALLBACK    CallBackFunction OPTIONAL,
  IN VOID                               *Context OPTIONAL
  );
```

Parameters

This

A pointer to the *EFI_USB2_HC_PROTOCOL* instance. Type EFI_USB2_HC_PROTOCOL is defined in *USB2 Host Controller Protocol* .

DeviceAddress

Represents the address of the target device on the USB, which is assigned during USB enumeration.

EndPointAddress
The combination of an endpoint number and an endpoint direction of the target USB device. Each endpoint address supports data transfer in one direction except the control endpoint (whose default endpoint address is zero). It is the caller's responsibility to make sure that the *EndPointAddress* represents an interrupt endpoint.

DeviceSpeed
Indicates device speed. See **Related Definitions** in *EFI_USB2_HC_PROTOCOL.ControlTransfer()* for a list of the supported values.

MaximumPacketLength
Indicates the maximum packet size the target endpoint is capable of sending or receiving.

IsNewTransfer
If **TRUE**, an asynchronous interrupt pipe is built between the host and the target interrupt endpoint. If **FALSE**, the specified asynchronous interrupt pipe is canceled. If **TRUE**, and an interrupt transfer exists for the target end point, then *EFI_INVALID_PARAMETER* is returned.

DataToggle
A pointer to the data toggle value. On input, it is valid when *IsNewTransfer* is **TRUE**, and it indicates the initial data toggle value the asynchronous interrupt transfer should adopt. On output, it is valid when *IsNewTransfer* is **FALSE**, and it is updated to indicate the data toggle value of the subsequent asynchronous interrupt transfer.

PollingInterval
Indicates the interval, in milliseconds, that the asynchronous interrupt transfer is polled. This parameter is required when *IsNewTransfer* is **TRUE**.

DataLength
Indicates the length of data to be received at the rate specified by *PollingInterval* from the target asynchronous interrupt endpoint. This parameter is only required when *IsNewTransfer* is **TRUE**.

Translator
A pointer to the transaction translator data.

CallBackFunction
The Callback function. This function is called at the rate specified by *PollingInterval*. This parameter is only required when *IsNewTransfer* is **TRUE**. Refer to *UsbAsyncInterruptTransfer()* in *USB I/O Protocol* for the definition of this function type.

Context
The context that is passed to the *CallBackFunction*. This is an optional parameter and may be **NULL**.

Description

This function is used to submit asynchronous interrupt transfer to a target endpoint of a USB device. The target endpoint is specified by *DeviceAddress* and *EndpointAddress*. In the USB Specification, Revision 2.0, interrupt transfer is one of the four USB transfer types. In the *EFI_USB2_HC_PROTOCOL*, interrupt transfer is divided further into synchronous interrupt transfer and asynchronous interrupt transfer.

An asynchronous interrupt transfer is typically used to query a device's status at a fixed rate. For example, keyboard, mouse, and hub devices use this type of transfer to query their interrupt endpoints at a fixed rate. The asynchronous interrupt transfer is intended to support the interrupt transfer type of "submit once, execute periodically." Unless an explicit request is made, the asynchronous transfer will never retire.

If *IsNewTransfer* is **TRUE**, then an interrupt transfer is started at a fixed rate. The rate is specified by *PollingInterval*, the size of the receive buffer is specified by *DataLength*, and the callback function is specified by *CallBackFunction*. *Context* specifies an optional context that is passed to the *CallBackFunction* each time it is called. The *CallBackFunction* is intended to provide a means for the host to periodically process interrupt transfer data.

If *IsNewTransfer* is **TRUE**, and an interrupt transfer exists for the target end point, then *EFI_INVALID_PARAMETER* is returned.

If *IsNewTransfer* is **FALSE**, then the interrupt transfer is canceled.

EFI_INVALID_PARAMETER is returned if one of the following conditions is satisfied:

- Data transfer direction indicated by *EndPointAddress* is other than *EfiUsbDataIn.*
- *IsNewTransfer* is **TRUE** and *DataLength* is 0.
- *IsNewTransfer* is **TRUE** and *DataToggle* points to a value other than 0 and 1.
- *IsNewTransfer* is **TRUE** and *PollingInterval* is not in the range 1..255.
- *IsNewTransfer* requested where an interrupt transfer exists for the target end point.

Status Codes Returned

EFI_SUCCESS	The asynchronous interrupt transfer request has been successfully submitted or canceled.
EFI_INVALID_PARAMETER	Some parameters are invalid. The possible invalid parameters are described in “Description” above. When an interrupt transfer exists for the target end point and a new transfer is requested, EFI_INVALID_PARAMETER is returned.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.

17.1.10 EFI_USB2_HC_PROTOCOL.SyncInterruptTransfer()

Summary

Submits synchronous interrupt transfer to an interrupt endpoint of a USB device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USB2_HC_PROTOCOL_SYNC_INTERRUPT_TRANSFER) (
  IN   EFI_USB2_HC_PROTOCOL                *This,
  IN   UINT8                               DeviceAddress,
  IN   UINT8                               EndPointAddress,
  IN   UINT8                               DeviceSpeed,
  IN   UINTN                               MaximumPacketLength,
  IN OUT VOID                              *Data,
  IN OUT UINTN                             *DataLength,
  IN OUT UINT8                             *DataToggle,
  IN   UINTN                                TimeOut,
  IN EFI_USB2_HC_TRANSACTION_TRANSLATOR    *Translator
  OUT UINT32                               *TransferResult
  );
```

Parameters

This

A pointer to the *EFI_USB2_HC_PROTOCOL* instance. Type EFI_USB2_HC_PROTOCOL is defined in *USB2 Host Controller Protocol* .

DeviceAddress

Represents the address of the target device on the USB, which is assigned during USB enumeration.

EndPointAddress

The combination of an endpoint number and an endpoint direction of the target USB device. Each endpoint address supports data transfer in one direction except the control endpoint (whose default endpoint address is zero). It is the caller's responsibility to make sure that the *EndPointAddress* represents an interrupt endpoint.

DeviceSpeed

Indicates device speed. See **Related Definitions** in *EFI_USB2_HC_PROTOCOL.ControlTransfer()* for a list of the supported values.

MaximumPacketLength

Indicates the maximum packet size the target endpoint is capable of sending or receiving.

Data

A pointer to the buffer of data that will be transmitted to USB device or received from USB device.

DataLength

On input, the size, in bytes, of the data buffer specified by *Data*. On output, the number of bytes transferred.

DataToggle

A pointer to the data toggle value. On input, it indicates the initial data toggle value the synchronous interrupt transfer should adopt; on output, it is updated to indicate the data toggle value of the subsequent synchronous interrupt transfer.

TimeOut

Indicates the maximum time, in milliseconds, which the transfer is allowed to complete.

Translator

A pointer to the transaction translator data.

TransferResult

A pointer to the detailed result information from the synchronous interrupt transfer. Refer to *UsbControlTransfer()* in *USB I/O Protocol* for transfer result types (*EFI_USB_ERR_x*).

Description

This function is used to submit a synchronous interrupt transfer to a target endpoint of a USB device. The target endpoint is specified by *DeviceAddress* and *EndpointAddress*. In the USB Specification, Revision2.0, interrupt transfer is one of the four USB transfer types. In the *EFI_USB2_HC_PROTOCOL* , interrupt transfer is divided further into synchronous interrupt transfer and asynchronous interrupt transfer.

The synchronous interrupt transfer is designed to retrieve small amounts of data from a USB device through an interrupt endpoint. A synchronous interrupt transfer is only executed once for each request. This is the most significant difference from the asynchronous interrupt transfer.

If the synchronous interrupt transfer is successful, then *EFI_SUCCESS* is returned. If the USB transfer cannot be completed within the timeout specified by *Timeout*, then *EFI_TIMEOUT* is returned. If an error other than timeout occurs during the USB transfer, then *EFI_DEVICE_ERROR* is returned and the detailed status code is returned in *TransferResult*.

EFI_INVALID_PARAMETER is returned if one of the following conditions is satisfied:

- *Data* is **NULL**.
- *DataLength* is 0.
- *MaximumPacketLength* is not valid. The legal value of this parameter should be 3072 or less for high-speed device, 64 or less for a full-speed device; for a slow device, it is limited to 8 or less. For the full-speed device, it should be 8, 16, 32, or 64; for the slow device, it is limited to 8.
- *DataToggle* points to a value other than 0 and 1.
- *TransferResult* is **NULL**.

Status Codes Returned

EFI_SUCCESS	The synchronous interrupt transfer was completed successfully.
EFI_OUT_OF_RESOURCES	The synchronous interrupt transfer could not be submitted due to lack of resource.
EFI_INVALID_PARAMETER	Some parameters are invalid. The possible invalid parameters are described in "Description" above.
EFI_TIMEOUT	The synchronous interrupt transfer failed due to timeout.
EFI_DEVICE_ERROR	The synchronous interrupt transfer failed due to host controller or device error. Caller should check TransferResult for detailed error information.

17.1.11 EFI_USB2_HC_PROTOCOL.IsochronousTransfer()

Summary

Submits isochronous transfer to an isochronous endpoint of a USB device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USB2_HC_PROTOCOL_ISOCHRONOUS_TRANSFER) (
  IN   EFI_USB2_HC_PROTOCOL                 *This,
  IN   UINT8                                DeviceAddress,
  IN   UINT8                                EndPointAddress,
  IN   UINT8                                DeviceSpeed,
  IN   UINTN                                MaximumPacketLength,
  IN   UINT8                                DataBuffersNumber,
  IN OUT VOID                               *Data[EFI_USB_MAX_ISO_BUFFER_NUM],
  IN   UINTN                                DataLength,
  IN   EFI_USB2_HC_TRANSACTION_TRANSLATOR   *Translator,
  OUT  UINT32                               *TransferResult
  );
```

Related Definitions

```
#define EFI_USB_MAX_ISO_BUFFER_NUM 7
#define EFI_USB_MAX_ISO_BUFFER_NUM1 2
```

Parameters

This

A pointer to the *EFI_USB2_HC_PROTOCOL* instance. Type EFI_USB2_HC_PROTOCOL is defined in *USB2 Host Controller Protocol* .

DeviceAddress

Represents the address of the target device on the USB, which is assigned during USB enumeration.

EndPointAddress

The combination of an endpoint number and an endpoint direction of the target USB device. Each endpoint address supports data transfer in one direction except the control endpoint (whose default endpoint address is 0). It is the caller's responsibility to make sure that the *EndPointAddress* represents an isochronous endpoint.

DeviceSpeed

Indicates device speed. The supported values are *EFI_USB_SPEED_FULL*, *EFI_USB_SPEED_HIGH*, or *EFI_USB_SPEED_SUPER*.

MaximumPacketLength
Indicates the maximum packet size the target endpoint is capable of sending or receiving. For isochronous endpoints, this value is used to reserve the bus time in the schedule, required for the per-frame data payloads. The pipe may, on an ongoing basis, actually use less bandwidth than that reserved.

DataBuffersNumber
Number of data buffers prepared for the transfer.

Data
Array of pointers to the buffers of data that will be transmitted to USB device or received from USB device.

DataLength
Specifies the length, in bytes, of the data to be sent to or received from the USB device.

Translator
A pointer to the transaction translator data. See ControlTransfer() "Description" for the detailed information of this data structure.

TransferResult
A pointer to the detail result information of the isochronous transfer. Refer to *UsbControlTransfer()* in *USB I/O Protocol* for transfer result types (*EFI_USB_ERR_x*).

Description

This function is used to submit isochronous transfer to a target endpoint of a USB device. The target endpoint is specified by *DeviceAddress* and *EndpointAddress*. Isochronous transfers are used when working with isochronous date. It provides periodic, continuous communication between the host and a device. Isochronous transfers can be used only by full-speed, high-speed, and super-speed devices.

High-speed isochronous transfers can be performed using multiple data buffers. The number of buffers that are actually prepared for the transfer is specified by *DataBuffersNumber*. For full-speed isochronous transfers this value is ignored.

Data represents a list of pointers to the data buffers. For full-speed isochronous transfers only the data pointed by *Data[0]* shall be used. For high-speed isochronous transfers and for the split transactions depending on *DataLength* there several data buffers can be used. For the high-speed isochronous transfers the total number of buffers must not exceed *EFI_USB_MAX_ISO_BUFFER_NUM*. For split transactions performed on full-speed device by high-speed host controller the total number of buffers is limited to *EFI_USB_MAX_ISO_BUFFER_NUM1* See **Related Definitions** for the *EFI_USB_MAX_ISO_BUFFER_NUM* and *EFI_USB_MAX_ISO_BUFFER_NUM1* values.

If the isochronous transfer is successful, then *EFI_SUCCESS* is returned. The isochronous transfer is designed to be completed within one USB frame time, if it cannot be completed, *EFI_TIMEOUT* is returned. If an error other than timeout occurs during the USB transfer, then *EFI_DEVICE_ERROR* is returned and the detailed status code will be returned in *TransferResult*.

EFI_INVALID_PARAMETER is returned if one of the following conditions is satisfied:

- *Data* is **NULL**.
- *DataLength* is 0.
- *DeviceSpeed* is not one of the supported values listed above.
- *MaximumPacketLength* is invalid. *MaximumPacketLength* must be 1023 or less for full-speed devices, and 1024 or less for high-speed and super-speed devices.
- *TransferResult* is **NULL**.

Status Codes Returned

EFI_SUCCESS	The isochronous transfer was completed successfully.
EFI_OUT_OF_RESOURCES	The isochronous transfer could not be submitted due to lack of resource.

continues on next page

Table 17.8 – continued from previous page

EFI_INVALID_PARAMETER	Some parameters are invalid. The possible invalid parameters are described in “Description” above.
EFI_TIMEOUT	The isochronous transfer cannot be completed within the one USB frame time.
EFI_DEVICE_ERROR	The isochronous transfer failed due to host controller or device error. Caller should check TransferResult for detailed error information.
EFI_UNSUPPORTED	The implementation doesn’t support an Isochronous transfer function.

17.1.12 EFI_USB2_HC_PROTOCOL.AsyncIsochronousTransfer()

Summary

Submits nonblocking isochronous transfer to an isochronous endpoint of a USB device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI * EFI_USB2_HC_PROTOCOL_ASYNC_ISOCHRONOUS_TRANSFER) (
  IN   EFI_USB2_HC_PROTOCOL                *This,
  IN   UINT8                               DeviceAddress,
  IN   UINT8                               EndPointAddress,
  IN   UINT8                               DeviceSpeed,
  IN   UINTN                               MaximumPacketLength,
  IN   UINT8                               DataBuffersNumber,
  IN OUT VOID                              *Data[EFI_USB_MAX_ISO_BUFFER_NUM],
  IN   UINTN                               DataLength,
  IN   EFI_USB2_HC_TRANSACTION_TRANSLATOR  *Translator,
  IN EFI_ASYNC_USB_TRANSFER_CALLBACK       IsochronousCallBack,
  IN VOID                                  *Context OPTIONAL
  );
```

Parameters

This

A pointer to the *EFI_USB2_HC_PROTOCOL* instance. Type EFI_USB2_HC_PROTOCOL is defined in *USB2 Host Controller Protocol* .

DeviceAddress

Represents the address of the target device on the USB, which is assigned during USB enumeration.

EndPointAddress

The combination of an endpoint number and an endpoint direction of the target USB device. Each endpoint address supports data transfer in one direction except the control endpoint (whose default endpoint address is zero). It is the caller’s responsibility to make sure that the *EndPointAddress* represents an isochronous endpoint.

DeviceSpeed

Indicates device speed. The supported values are *EFI_USB_SPEED_FULL*, *EFI_USB_SPEED_HIGH*, or *EFI_USB_SPEED_SUPER*.

MaximumPacketLength

Indicates the maximum packet size the target endpoint is capable of sending or receiving. For isochronous endpoints, this value is used to reserve the bus time in the schedule, required for the per-frame data payloads. The pipe may, on an ongoing basis, actually use less bandwidth than that reserved.

DataBuffersNumber
Number of data buffers prepared for the transfer.

Data
Array of pointers to the buffers of data that will be transmitted to USB device or received from USB device.

DataLength
Specifies the length, in bytes, of the data to be sent to or received from the USB device.

Translator
A pointer to the transaction translator data. See ControlTransfer() "Description" for the detailed information of this data structure.

IsochronousCallback
The Callback function. This function is called if the requested isochronous transfer is completed. Refer to *UsbAsyncInterruptTransfer()* in *USB I/O Protocol* for the definition of this function type.

Context
Data passed to the *IsochronousCallback* function. This is an optional parameter and may be **NULL**.

Description

This is an asynchronous type of USB isochronous transfer. If the caller submits a USB isochronous transfer request through this function, this function will return immediately. When the isochronous transfer completes, the *IsochronousCallback* function will be triggered, the caller can know the transfer results. If the transfer is successful, the caller can get the data received or sent in this callback function.

The target endpoint is specified by *DeviceAddress* and *EndpointAddress*. Isochronous transfers are used when working with isochronous date. It provides periodic, continuous communication between the host and a device. Isochronous transfers can be used only by full-speed, high-speed, and super-speed devices.

High-speed isochronous transfers can be performed using multiple data buffers. The number of buffers that are actually prepared for the transfer is specified by *DataBuffersNumber*. For full-speed isochronous transfers this value is ignored.

Data represents a list of pointers to the data buffers. For full-speed isochronous transfers only the data pointed by *Data[0]* shall be used. For high-speed isochronous transfers and for the split transactions depending on *DataLength* there several data buffers can be used. For the high-speed isochronous transfers the total number of buffers must not exceed *EFI_USB_MAX_ISO_BUFFER_NUM*. For split transactions performed on full-speed device by high-speed host controller the total number of buffers is limited to *EFI_USB_MAX_ISO_BUFFER_NUM1* See **Related Definitions** in IsochronousTransfer() section for the *EFI_USB_MAX_ISO_BUFFER_NUM* and *EFI_USB_MAX_ISO_BUFFER_NUM1* values.

EFI_INVALID_PARAMETER is returned if one of the following conditions is satisfied:

- *Data* is **NULL**.
- *DataLength* is 0.
- *DeviceSpeed* is not one of the supported values listed above.
- *MaximumPacketLength* is invalid. *MaximumPacketLength* must be 1023 or less for full-speed devices and 1024 or less for high-speed and super-speed devices.

Status Codes Returned

EFI_SUCCESS	The asynchronous isochronous transfer was completed successfully.
EFI_OUT_OF_RESOURCES	The asynchronous isochronous transfer could not be submitted due to lack of resource.
EFI_INVALID_PARAMETER	Some parameters are invalid. The possible invalid parameters are described in "Description" above.

EFI_UNSUPPORTED	The implementation doesn't support Isochronous transfer function

17.1.13 EFI_USB2_HC_PROTOCOL.GetRootHubPortStatus()

Summary

Retrieves the current status of a USB root hub port.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USB2_HC_PROTOCOL_GET_ROOTHUB_PORT_STATUS) (
  IN EFI_USB2_HC_PROTOCOL            *This,
  IN UINT8                           PortNumber,
  OUT EFI_USB_PORT_STATUS            *PortStatus
  );
```

Parameters

This

A pointer to the *EFI_USB2_HC_PROTOCOL* instance. Type EFI_USB2_HC_PROTOCOL is defined in *USB2 Host Controller Protocol* .

PortNumber

Specifies the root hub port from which the status is to be retrieved. This value is zero based. For example, if a root hub has two ports, then the first port is numbered 0, and the second port is numbered 1.

PortStatus

A pointer to the current port status bits and port status change bits. The type EFI_USB_PORT_STATUS is defined in **Related Definitions** below.

Related Definitions

```
typedef struct {
  UINT16               PortStatus;
  UINT16               PortChangeStatus;

```

PortStatus

Contains current port status bitmap. The root hub port status bitmap is unified with the USB hub port status bitmap. See Table below, *USB Hub Port Status Bitmap*, for a reference, which is borrowed from Chapter 11, Hub Specification, of USB Specification, Revision 1.1.

PortChangeStatus

Contains current port status change bitmap. The root hub port change status bitmap is unified with the USB hub port status bitmap. See Table below, *Hub Port Change Status Bitmap* for a reference, which is borrowed from Chapter 11, Hub Specification, of USB Specification, Revision 1.1.

Table 17.10: USB Hub Port Status Bitmap

Bit	Description
0	Current Connect Status: (USB_PORT_STAT_CONNECTION) This field reflects whether or not a device is currently connected to this port. 0 = No device is present 1 = A device is present on this port
1	Port Enable / Disabled: (USB_PORT_STAT_ENABLE) Ports can be enabled by software only. Ports can be disabled by either a fault condition (disconnect event or other fault condition) or by software. 0 = Port is disabled 1 = Port is enabled
2	Suspend: (USB_PORT_STAT_SUSPEND) This field indicates whether or not the device on this port is suspended. 0 = Not suspended 1 = Suspended
3	Over-current Indicator: (USB_PORT_STAT_OVERCURRENT) This field is used to indicate that the current drain on the port exceeds the specified maximum. 0 = All no over-current condition exists on this port 1 = An over-current condition exists on this port

continues on next page

Table 17.10 – continued from previous page

4	Reset: (USB_PORT_STAT_RESET) Indicates whether port is in reset state. 0 = Port is not in reset state 1 = Port is in reset state
5-7	Reserved These bits return 0 when read.
8	Port Power: (USB_PORT_STAT_POWER) This field reflects a port's logical, power control state. 0 = This port is in the Powered-off state 1 = This port is not in the Powered-off state
9	Low Speed Device Attached: (USB_PORT_STAT_LOW_SPEED) This is relevant only if a device is attached. 0 = Full-speed device attached to this port 1 = Low-speed device attached to this port
10	High Speed Device Attached: (USB_PORT_STAT_HIGH_SPEED) This field indicates whether the connected device is high-speed device 0 = High-speed device is not attached to this port 1 = High-speed device attached to this port NOTE: this bit has precedence over Bit 9; if set, bit 9 must be ignored.
11	Super Speed Device Attached: (USB_PORT_STAT_SUPER_SPEED) This field indicates whether the connected device is a super-speed device. 0 = Super-speed device is not attached to this port. 1 = Super-speed device is attached to this port. NOTE: This bit bas precedence over Bit 9 and Bit 10; if set bits 9,10 must be ignored.
12	Reserved. Bit returns 0 when read.
13	The host controller owns the specified port. 0 = Controller does not own the port. 1 = Controller owns the port
14-15	Reserved These bits return 0 when read.

Table 17.11: Hub Port Change Status Bitmap

Bit	Description

continues on next page

Table 17.11 – continued from previous page

0	Connect Status Change: (USB_PORT_STAT_C_CONNECTION) Indicates a change has occurred in the port's Current Connect Status. 0 = No change has occurred to Current Connect status 1 = Current Connect status has changed
1	Port Enable /Disable Change: (USB_PORT_STAT_C _ENABLE) 0 = No change 1 = Port enabled/disabled status has changed
2	Suspend Change: (USB_PORT_STAT_C _SUSPEND) This field indicates a change in the host-visible suspend state of the attached device. 0 = No change 1 = Resume complete
3	Over-Current Indicator Change: (USB_PORT_STAT_C_OVERCURRENT) 0 = No change has occurred to Over-Current Indicator 1 = Over-Current Indicator has changed
4	Reset Change: (USB_PORT_STAT_C_RESET) This field is set when reset processing on this port is complete. 0 = No change 1 = Reset complete
5-15	Reserved. These bits return 0 when read.

Description

This function is used to retrieve the status of the root hub port specified by *PortNumber*.

EFI_USB_PORT_STATUS found in **Related Definitions** *EFI_USB2_HC_PROTOCOL.GetRootHubPortStatus()* describes the port status of a specified USB port. This data structure is designed to be common to both a USB root hub port and a USB hub port.

The number of root hub ports attached to the USB host controller can be determined with the function *EFI_USB2_HC_PROTOCOL.GetRootHubPortStatus()*. If *PortNumber* is greater than or equal to the number of ports returned by *GetRootHubPortNumber()*, then *EFI_INVALID_PARAMETER* is returned. Otherwise, the status of the USB root hub port is returned in *PortStatus*, and *EFI_SUCCESS* is returned.

Status Codes Returned

EFI_SUCCESS	The status of the USB root hub port specified by PortNumber was returned in PortStatus.
EFI_INVALID_PARAMETER	PortNumber is invalid.

17.1.14 EFI_USB2_HC_PROTOCOL.SetRootHubPortFeature()

Summary

Sets a feature for the specified root hub port.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USB2_HC_PROTOCOL_SET_ROOTHUB_PORT_FEATURE) (
  IN EFI_USB2_HC_PROTOCOL      *This,
  IN UINT8                     PortNumber,
  IN EFI_USB_PORT_FEATURE      PortFeature
  );
```

Parameters

This

A pointer to the *EFI_USB2_HC_PROTOCOL* instance. Type EFI_USB2_HC_PROTOCOL is defined in *USB2 Host Controller Protocol* .

PortNumber

Specifies the root hub port whose feature is requested to be set. This value is zero based. For example, if a root hub has two ports, then the first port is number 0, and the second port is numbered 1.

PortFeature

Indicates the feature selector associated with the feature set request. The port feature indicator is defined in **Related Definitions** and The Table below, *USB Port Features*.

Related Definitions

```
typedef enum {
  EfiUsbPortEnable              = 1,
  EfiUsbPortSuspend             = 2,
  EfiUsbPortReset               = 4,
  EfiUsbPortPower               = 8,
  EfiUsbPortOwner               = 13,
  EfiUsbPortConnectChange       = 16,
  EfiUsbPortEnableChange        = 17,
  EfiUsbPortSuspendChange       = 18,
  EfiUsbPortOverCurrentChange   = 19,
  EfiUsbPortResetChange         = 20
}  EFI_USB_PORT_FEATURE;
```

The feature values specified in the enumeration variable have special meaning. Each value indicates its bit index in the port status and status change bitmaps, if combines these two bitmaps into a 32-bit bitmap. The meaning of each port feature is listed in Table below, *USB Port Features*.

Table 17.12: USB Port Features

Port Feature	For SetRootHubPortFeature	For Cl earRootHubPortFeature
EfiUsbPortEnable	Enable the given port of the root hub.	Disable the given port of the root hub.
EfiUsbPortSuspend	Put the given port into suspend state.	Restore the given port from the previous suspend state.

continues on next page

Table 17.12 – continued from previous page

EfiUsbPortReset	Reset the given port of the root hub.	Clear the RESET signal for the given port of the root hub.
EfiUsbPortPower	Power the given port.	Shutdown the power from the given port.
EfiUsbPortOwner	N/A.	Releases the port ownership of this port to companion host controller.
Ef iUsbPortConnectChange	N/A.	Clear USB_PORT_STAT_C_CONNECTION bit of the given port of the root hub.
E fiUsbPortEnableChange	N/A.	Clear USB_PORT_STAT_C_ENABLE bit of the given port of the root hub.
Ef iUsbPortSuspendChange	N/A.	Clear USB_PORT_STAT_C_SUSPEND bit of the given port of the root hub.
EfiUsb PortOverCurrentChange	N/A.	Clear USB_PORT_STAT_C_OVERCURRENT bit of the given port of the root hub.
EfiUsbPortResetChange	N/A.	Clear USB_PORT_STAT_C_RESET bit of the given port of the root hub.

Description

This function sets the feature specified by *PortFeature* for the USB root hub port specified by *PortNumber*. Setting a feature enables that feature or starts a process associated with that feature. For the meanings about the defined features, refer to Table *USB Hub Port Status Bitmap* and Table *Hub Port Change Status Bitmap*.

The number of root hub ports attached to the USB host controller can be determined with the function *EFI_USB2_HC_PROTOCOL.GetRootHubPortStatus()*. If *PortNumber* is greater than or equal to the number of ports returned by *GetRootHubPortNumber()*, then *EFI_INVALID_PARAMETER* is returned. If *PortFeature* is not *EfiUsbPortEnable*, *EfiUsbPortSuspend*, *EfiUsbPortReset* nor *EfiUsbPortPower*, then *EFI_INVALID_PARAMETER* is returned.

Status Codes Returned

EFI_SUCCESS	The feature specified by PortFeature was set for the USB root hub port specified by PortNumber.
EFI_INVALID_PARAMETER	PortNumber is invalid or PortFeature is invalid for this function.

17.1.15 EFI_USB2_HC_PROTOCOL.ClearRootHubPortFeature()

Summary

Clears a feature for the specified root hub port.

Prototype

```
typede
EFI_STATUS
(EFIAPI *EFI_USB2_HC_PROTOCOL_CLEAR_ROOTHUB_PORT_FEATURE) (
  IN EFI_USB2_HC_PROTOCOL      *This
  IN UINT8                     PortNumber,
```

(continues on next page)

(continued from previous page)

```
  IN EFI_USB_PORT_FEATURE       PortFeature
  );
```

Parameters

This

A pointer to the *EFI_USB2_HC_PROTOCOL* instance, which is defined in *USB2 Host Controller Protocol*.

PortNumber

Specifies the root hub port whose feature is requested to be cleared. This value is zero-based. For example, if a root hub has two ports, then the first port is number 0, and the second port is numbered 1.

PortFeature

Indicates the feature selector associated with the feature clear request. The port feature indicator EFI_USB_PORT_FEATURE is defined in Section 17.1.14 in the "Related Definitions" section, and in Table 17.12.

Description

This function clears the feature specified by PortFeature for the USB root hub port specified by PortNumber. Clearing a feature disables that feature or stops a process associated with that feature. For the meanings about the defined features, refer to Table *USB Hub Port Status Bitmap* and Table *Hub Port Change Status Bitmap*.

The number of root hub ports attached to the USB host controller can be determined with the function *EFI_USB2_HC_PROTOCOL.GetRootHubPortStatus()*. If PortNumber is greater than or equal to the number of ports returned by GetRootHubPortNumber(), then EFI_INVALID_PARAMETER is returned. If PortFeature is not EfiUsbPortEnable, EfiUsbPortSuspend, EfiUsbPortPower, EfiUsbPortConnectChange, EfiUsbPortResetChange, EfiUsbPortEnableChange, EfiUsbPortSuspendChange, or EfiUsbPortOverCurrentChange, then EFI_INVALID_PARAMETER is returned.

Status Codes Returned

EFI_SUCCESS	The feature specified by PortFeature was cleared for the USB root hub port specified by PortNumber.
EFI_INVALID_PARAMETER	PortNumber is invalid or PortFeature is invalid.

17.2 USB Driver Model

17.2.1 Scope

Section *USB Driver Model* describes the USB Driver Model. This includes the behavior of USB Bus Drivers, the behavior of a USB Device Drivers, and a detailed description of the EFI USB I/O Protocol. This document provides enough material to implement a USB Bus Driver, and the tools required to design and implement USB Device Drivers. It does not provide any information on specific USB devices.

The material contained in this section is designed to extend this specification and the UEFI Driver Model in a way that supports USB device drivers and USB bus drivers. These extensions are provided in the form of USB specific protocols. This document provides the information required to implement a USB Bus Driver in system firmware. The document also contains the information required by driver writers to design and implement USB Device Drivers that a platform may need to boot a UEFI-compliant OS.

The USB Driver Model described here is intended to be a foundation on which a USB Bus Driver and a wide variety of USB Device Drivers can be created. USB Driver Model Overview

The USB Driver Stack includes the USB Bus Driver, USB Host Controller Driver, and individual USB device drivers.

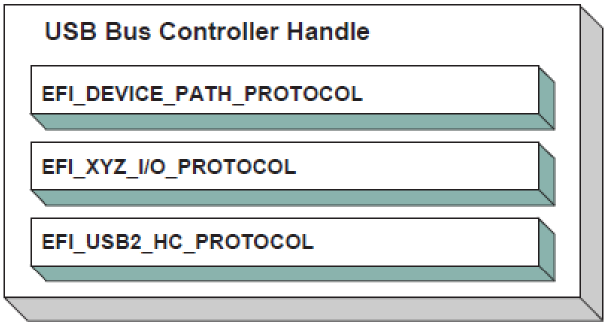

Fig. 17.2: USB Bus Controller Handle

In the USB Bus Driver Design, the USB Bus Controller is managed by two drivers. One is USB Host Controller Driver, which consumes its parent bus *EFI_XYZ_IO_PROTOCOL*, and produces EFI_USB2_HC_PROTOCOL, and attaches it to the Bus Controller Handle. The other one is USB Bus Driver, which consumes *EFI_USB2_HC_PROTOCOL*, and performs bus enumeration. Figure *USB Bus Controller Handle* shows protocols that are attached to the USB Bus Controller Handle. Detailed descriptions are presented in the following sections.

17.2.2 USB Bus Driver

USB Bus Driver performs periodic Enumeration on the USB Bus. In USB bus enumeration, when a new USB controller is found, the bus driver does some standard configuration for that new controller, and creates a device handle for it. The EFI_USB_IO_PROTOCOL and EFI_DEVICE_PATH_PROTOCOL are attached to the device handle so that the USB controller can be accessed. The USB Bus Driver is also responsible for connecting USB device drivers to USB controllers. When a USB device is detached from a USB bus, the USB bus driver will stop that USB controller, and uninstall the *EFI_USB_IO_PROTOCOL* and the *EFI_DEVICE_PATH_PROTOCOL* from that handle. A detailed description is given in *USB Hot-Plug Event*.

17.2.2.1 USB Bus Driver Entry Point

Like all other device drivers, the entry point for a USB Bus Driver attaches the *EFI Driver Binding Protocol* to image handle of the USB Bus Driver.

17.2.2.2 Driver Binding Protocol for USB Bus Drivers

The Driver Binding Protocol contains three services. These are:
EFI_DRIVER_BINDING_PROTOCOL.Supported(),
EFI_DRIVER_BINDING_PROTOCOL.Start() and
EFI_DRIVER_BINDING_PROTOCOL.Stop()

Supported() tests to see if the USB Bus Driver can manage a device handle. A USB Bus Driver can only manage a device handle that contains *EFI_USB2_HC_PROTOCOL.*

The general idea is that the USB Bus Driver is a generic driver. Since there are several types of USB Host Controllers, an *EFI_USB2_HC_PROTOCOL* is used to abstract the host controller interface. Actually, a USB Bus Driver only requires an *EFI_USB2_HC_PROTOCOL.*

The *Start()* function tells the USB Bus Driver to start managing the USB Bus. In this function, the USB Bus Driver creates a device handle for the root hub, and creates a timer to monitor root hub connection changes.

The *Stop()* function tells the USB Bus Driver to stop managing a USB Host Bus Controller. The *Stop()* function simply deconfigures the devices attached to the root hub. The deconfiguration is a recursive process. If the device to be deconfigured is a USB hub, then all USB devices attached to its downstream ports will be deconfigured first, then itself. If all of the child devices handles have been destroyed then the *EFI_USB2_HC_PROTOCOL* is closed. Finally, the *Stop()* unction will then place the USB Host Bus Controller in a quiescent state.

17.2.2.3 USB Hot-Plug Event

Hot-Plug is one of the most important features provided by USB. A USB bus driver implements this feature through two methods. There are two types of hubs defined in the USB specification. One is the USB root hub, which is implemented in the USB Host controller. A timer event is created for the root hub. The other one is a USB Hub. An event is created for each hub that is correctly configured. All these events are associated with the same trigger which is USB bus numerator.

When USB bus enumeration is triggered, the USB Bus Driver checks the source of the event. This is required because the root hub differs from standard USB hub in checking the hub status. The status of a root hub is retrieved through the *EFI_USB2_HC_PROTOCOL*, and that status of a standard USB hub is retrieved through a USB control transfer. A detailed description of the enumeration process is presented in the next section.

17.2.2.4 USB Bus Enumeration

When the periodic timer or the hubs notify event is signaled, the USB Bus Driver will perform bus numeration.

1. Determine if the event is from the roothub or a standard USB hub.
2. Determine the port on which the connection change event occurred.
3. Determine if it is a connection change or a disconnection change.
4. If a connect change is detected, then a new device has been attached. Perform the following:

   a – Reset and enable that port.

   b – Configure the new device.

   c – Parse the device configuration descriptors; get all of its interface descriptors (i.e., all USB controllers), and configure each interface.

   d – Create a new handle for each interface (USB Controller) within the USB device. Attach the *EFI Device Path Protocol*, and *EFI_USB_IO_PROTOCOL* to each handle.

   e – Connect the USB Controller to a USB device driver with the Boot Service *EFI_BOOT_SERVICES.ConnectController()* if applicable.

   f – If the USB Controller is a USB hub, create a Hub notify event which is associated with the USB Bus Enumerator, and submit an Asynchronous Interrupt Transfer Request (*USB I/O Protocol*).

5. If a disconnect change, then a device has been detached from the USB Bus. Perform the following:

   a – If the device is not a USB Hub, then find and deconfigure the USB Controllers within the device. Then, stop each USB controller with *EFI_BOOT_SERVICES.DisconnectController()*, and uninstall the *EFI_DEVICE_PATH_PROTOCOL* and the *EFI_USB_IO_PROTOCOL* from the controller's handle. If the *EFI_BOOT_SERVICES.DisconnectController()* call fails this process must be retried on a subsequent timer tick.

   b – If the USB controller is USB hub controller, first find and deconfigure all its downstream USB devices (this is a recursive process, since there may be additional USB hub controllers on the downstream ports), then deconfigure USB hub controller itself.

17.2.3 USB Device Driver

A USB Device Driver manages a USB Controller and produces a device abstraction for use by a preboot application.

17.2.3.1 USB Device Driver Entry Point

Like all other device drivers, the entry point for a USB Device Driver attaches *EFI Driver Binding Protocol* to image handle of the USB Device Driver.

17.2.3.2 Driver Binding Protocol for USB DeviceDrivers

The Driver Binding Protocol contains three services. These are:
EFI_DRIVER_BINDING_PROTOCOL.Supported(),
EFI_DRIVER_BINDING_PROTOCOL.Start() and
EFI_DRIVER_BINDING_PROTOCOL.Stop()

The *Supported()* tests to see if the USB Device Driver can manage a device handle. This function checks to see if a controller can be managed by the USB Device Driver. This is done by opening the See *EFI_USB_IO_PROTOCOL* bus abstraction on the USB Controller handle, and using the *EFI_USB_IO_PROTOCOL* services to determine if this USB Controller matches the profile that the USB Device Driver is capable of managing.

The *Start()* function tells the USB Device Driver to start managing a USB Controller. It opens the *EFI_USB_IO_PROTOCOL* instance from the handle for the USB Controller. This protocol instance is used to perform USB packet transmission over the USB bus. For example, if the USB controller is USB keyboard, then the USB keyboard driver would produce and install the *EFI_SIMPLE_TEXT_INPUT_PROTOCOL* to the USB controller handle.

The *Stop()* function tells the USB Device Driver to stop managing a USB Controller. It removes the I/O abstraction protocol instance previously installed in *Start()* from the USB controller handle. It then closes the *EFI_USB_IO_PROTOCOL*.

17.2.4 USB I/O Protocol

This section provides a detailed description of the *EFI_USB_IO_PROTOCOL*. This protocol is used by code, typically drivers, running in the EFI boot services environment to access USB devices like USB keyboards, mice and mass storage devices. In particular, functions for managing devices on USB buses are defined here.

The interfaces provided in the *EFI_USB_IO_PROTOCOL* are for performing basic operations to access USB devices. Typically, USB devices are accessed through the four different transfers types:

Controller Transfer
Typically used to configure the USB device into an operation mode.

Interrupt Transfer
Typically used to get periodic small amount of data, like USB keyboard and mouse.

Bulk Transfer
Typically used to transfer large amounts of data like reading blocks from USB mass storage devices.

Isochronous Transfer
Typically used to transfer data at a fixed rate like voice data.

This protocol also provides mechanisms to manage and configure USB devices and controllers.

17.2.5 EFI_USB_IO_PROTOCOL

Summary

Provides services to manage and communicate with USB devices.

GUID

```
#define EFI_USB_IO_PROTOCOL_GUID \
  {0x2B2F68D6,0x0CD2,0x44cf,\
    {0x8E,0x8B,0xBB,0xA2,0x0B,0x1B,0x5B,0x75}}
```

Protocol Interface Structure

```
typedef struct _EFI_USB_IO_PROTOCOL {
  EFI_USB_IO_CONTROL_TRANSFER           UsbControlTransfer;
  EFI_USB_IO_BULK_TRANSFER              UsbBulkTransfer;
  EFI_USB_IO_ASYNC_INTERRUPT_TRANSFER   UsbAsyncInterruptTransfer;
  EFI_USB_IO_SYNC_INTERRPUT_TRANSFER    UsbSyncInterruptTransfer
  EFI_USB_IO_ISOCHRONOUS_TRANSFER       UsbIsochronousTransfer;
  EFI_USB_IO_ASYNC_ISOCHRONOUS_TRANSFER UsbAsyncIsochronousTransfer;
  EFI_USB_IO_GET_DEVICE_DESCRIPTOR      UsbGetDeviceDescriptor;
  EFI_USB_IO_GET_CONFIG_DESCRIPTOR      UsbGetConfigDescriptor;
  EFI_USB_IO_GET_INTERFACE_DESCRIPTOR   UsbGetInterfaceDescriptor;
  EFI_USB_IO_GET_ENDPOINT_DESCRIPTOR    UsbGetEndpointDescriptor;
  EFI_USB_IO_GET_STRING_DESCRIPTOR      UsbGetStringDescriptor;
  EFI_USB_IO_GET_SUPPORTED_LANGUAGES    UsbGetSupportedLanguages;
  EFI_USB_IO_PORT_RESET                 UsbPortReset;
} EFI_USB_IO_PROTOCOL;
```

Parameters

UsbControlTransfer
Accesses the USB Device through USB Control Transfer Pipe. See the *EFI_USB_IO_PROTOCOL.UsbControlTransfer()* function description.

UsbBulkTransfer
Accesses the USB Device through USB Bulk Transfer Pipe. See the *EFI_USB_IO_PROTOCOL.UsbBulkTransfer()* function description.

UsbAsyncInterruptTransfer
Non-block USB interrupt transfer. See the *EFI_USB_IO_PROTOCOL.UsbAsyncInterruptTransfer()* function description.

UsbSyncInterruptTransfer
Accesses the USB Device through USB Synchronous Interrupt Transfer Pipe. See the *EFI_USB_IO_PROTOCOL.UsbSyncInterruptTransfer()* function description.

UsbIsochronousTransfer
Accesses the USB Device through USB Isochronous Transfer Pipe. See the *EFI_USB_IO_PROTOCOL.UsbIsochronousTransfer()* function description.

UsbAsyncIsochronousTransfer
Nonblock USB isochronous transfer. See the *EFI_USB_IO_PROTOCOL.UsbAsyncIsochronousTransfer()* function description.

UsbGetDeviceDescriptor
Retrieves the device descriptor of a USB device. See the *EFI_USB_IO_PROTOCOL.UsbGetDeviceDescriptor()* function description.

UsbGetConfigDescriptor
Retrieves the activated configuration descriptor of a USB device. See the *EFI_USB_IO_PROTOCOL.UsbGetConfigDescriptor()* function description.

UsbGetInterfaceDescriptor
Retrieves the interface descriptor of a USB Controller. See the *EFI_USB_IO_PROTOCOL.UsbGetInterfaceDescriptor()* function description.

UsbGetEndpointDescriptor
Retrieves the endpoint descriptor of a USB Controller. See the *EFI_USB_IO_PROTOCOL.UsbGetEndpointDescriptor()* function description.

UsbGetStringDescriptor
Retrieves the string descriptor inside a USB Device. See the *EFI_USB_IO_PROTOCOL.UsbGetStringDescriptor()* function description.

UsbGetSupportedLanguages
Retrieves the array of languages that the USB device supports. See the *EFI_USB_IO_PROTOCOL.UsbGetSupportedLanguages()* function description.

UsbPortReset
Resets and reconfigures the USB controller. See the *EFI_USB_IO_PROTOCOL.UsbPortReset()* function description.

Description

The *EFI_USB_IO_PROTOCOL* provides four basic transfers types described in the USB 1.1 Specification. These include control transfer, interrupt transfer, bulk transfer and isochronous transfer. The *EFI_USB_IO_PROTOCOL* also provides some basic USB device/controller management and configuration interfaces. A USB device driver uses the services of this protocol to manage USB devices.

17.2.6 EFI_USB_IO_PROTOCOL.UsbControlTransfer()

Summary

This function is used to manage a USB device with a control transfer pipe. A control transfer is typically used to perform device initialization and configuration.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USB_IO_CONTROL_TRANSFER) (
  IN EFI_USB_IO_PROTOCOL           *This,
  IN EFI_USB_DEVICE_REQUEST        *Request,
  IN EFI_USB_DATA_DIRECTION        Direction,
  IN UINT32                        Timeout,
  IN OUT VOID                      *Data OPTIONAL,
  IN UINTN                         DataLength OPTIONAL,
  OUT UINT32                       *Status
  );
```

Parameters

This
A pointer to the *EFI_USB_IO_PROTOCOL* instance. Type EFI_USB_IO_PROTOCOL is defined in *USB I/O Protocol* .

Request

A pointer to the USB device request that will be sent to the USB device. See **Related Definitions** below.

Direction

Indicates the data direction. See **Related Definitions** below for this type.

Data

A pointer to the buffer of data that will be transmitted to USB device or received from USB device.

Timeout

Indicating the transfer should be completed within this time frame. The units are in milliseconds. If *Timeout* is 0, then the caller must wait for the function to be completed until EFI_SUCCESS or EFI_DEVICE_ERROR is returned.

DataLength

The size, in bytes, of the data buffer specified by *Data*.

Status

A pointer to the result of the USB transfer.

Related Definitions

```
typedef enum {
  EfiUsbDataIn,
  EfiUsbDataOut,
  EfiUsbNoData
}   EFI_USB_DATA_DIRECTION;

  //
  // Error code for USB Transfer Results
  //
  #define EFI_USB_NOERROR             0x0000
  #define EFI_USB_ERR_NOTEXECUTE      0x0001
  #define EFI_USB_ERR_STALL           0x0002
  #define EFI_USB_ERR_BUFFER          0x0004
  #define EFI_USB_ERR_BABBLE          0x0008
  #define EFI_USB_ERR_NAK             0x0010
  #define EFI_USB_ERR_CRC             0x0020
  #define EFI_USB_ERR_TIMEOUT         0x0040
  #define EFI_USB_ERR_BITSTUFF        0x0080
  #define EFI_USB_ERR_SYSTEM          0x0100

typedef struct {
  UINT8               RequestType;
  UINT8               Request;
  UINT16              Value;
  UINT16              Index;
  UINT16              Length;
}   EFI_USB_DEVICE_REQUEST;
```

RequestType

The field identifies the characteristics of the specific request.

Request

This field specifies the particular request.

Value

This field is used to pass a parameter to USB device that is specific to the request.

Index

This field is also used to pass a parameter to USB device that is specific to the request.

Length

This field specifies the length of the data transferred during the second phase of the control transfer. If it is 0, then there is no data phase in this transfer.

Description

This function allows a USB device driver to communicate with the USB device through a Control Transfer. There are three control transfer types according to the data phase. If the *Direction* parameter is *EfiUsbNoData*, *Data* is **NULL**, and *DataLength* is 0, then no data phase exists for the control transfer. If the *Direction* parameter is *EfiUsbDataOut*, then *Data* specifies the data to be transmitted to the device, and *DataLength* specifies the number of bytes to transfer to the device. In this case there is an OUT DATA stage followed by a SETUP stage. If the *Direction* parameter is *EfiUsbDataIn*, then *Data* specifies the data that is received from the device, and *DataLength* specifies the number of bytes to receive from the device. In this case there is an IN DATA stage followed by a SETUP stage. After the USB transfer has completed successfully, *EFI_SUCCESS* is returned. If the transfer cannot be completed due to timeout, then *EFI_TIMEOUT* is returned. If an error other than timeout occurs during the USB transfer, then *EFI_DEVICE_ERROR* is returned and the detailed status code is returned in *Status*.

Status Codes Returned

EFI_SUCCESS	The control transfer has been successfully executed.
EFI_INVALID_PARAMETER	The parameter Direction is not valid.
EFI_INVALID_PARAMETER	Request is **NULL**.
EFI-INVALID_PARAMETER	Status is **NULL**.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.
EFI_TIMEOUT	The control transfer fails due to timeout.
EFI_DEVICE_ERROR	The transfer failed. The transfer status is returned in Status.

17.2.7 EFI_USB_IO_PROTOCOL.UsbBulkTransfer()

Summary

This function is used to manage a USB device with the bulk transfer pipe. Bulk Transfers are typically used to transfer large amounts of data to/from USB devices.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USB_IO_BULK_TRANSFER) (
  IN   EFI_USB_IO_PROTOCOL         *This,
  IN   UINT8                       DeviceEndpoint,
  IN   OUT VOID                    *Data,
  IN OUT UINTN                     *DataLength,
  IN   UINTN                       Timeout,
  OUT  UINT32                      *Status
  );
```

Parameters

This

A pointer to the *EFI_USB_IO_PROTOCOL* instance. Type EFI_USB_IO_PROTOCOL is defined in *USB I/O Protocol* .

DeviceEndpoint

The destination USB device endpoint to which the device request is being sent. DeviceEndpoint must be between 0x01 and 0x0F or between 0x81 and 0x8F, otherwise EFI_INVALID_PARAMETER is returned. If the endpoint is not a BULK endpoint, EFI_INVALID_PARAMETER is returned. The MSB of this parameter indicates the endpoint direction. The number "1" stands for an IN endpoint, and "0" stands for an OUT endpoint.

Data

A pointer to the buffer of data that will be transmitted to USB device or received from USB device.

DataLength

On input, the size, in bytes, of the data buffer specified by Data. On output, the number of bytes that were actually transferred.

Timeout

Indicating the transfer should be completed within this time frame. The units are in milliseconds. If Timeout is 0, then the caller must wait for the function to be completed until EFI_SUCCESS or EFI_DEVICE_ERROR is returned.

Status

This parameter indicates the USB transfer status.

Description

This function allows a USB device driver to communicate with the USB device through Bulk Transfer. The transfer direction is determined by the endpoint direction. If the USB transfer is successful, then *EFI_SUCCESS* is returned. If USB transfer cannot be completed within the *Timeout* frame, *EFI_TIMEOUT* is returned. If an error other than timeout occurs during the USB transfer, then *EFI_DEVICE_ERROR* is returned and the detailed status code will be returned in the *Status* parameter.

Status Codes Returned

EFI_SUCCESS	The bulk transfer has been successfully executed.
EFI_INVALID_PARAMETER	If DeviceEndpoint is not valid.
EFI_INVALID_PARAMETER	Data is **NULL**.
EFI_INVALID_PARAMETER	DataLength is **NULL**.
EFI_INVALID_PARAMETER	Status is **NULL**.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.
EFI_TIMEOUT	The bulk transfer cannot be completed within Timeout timeframe.
EFI_DEVICE_ERROR	The transfer failed other than timeout, and the transfer status is returned in Status.

17.2.8 EFI_USB_IO_PROTOCOL.UsbAsyncInterruptTransfer()

Summary

This function is used to manage a USB device with an interrupt transfer pipe. An Asynchronous Interrupt Transfer is typically used to query a device's status at a fixed rate. For example, keyboard, mouse, and hub devices use this type of transfer to query their interrupt endpoints at a fixed rate.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USB_IO_ASYNC_INTERRUPT_TRANSFER) (
  IN EFI_USB_IO_PROTOCOL              *This,
  IN UINT8                            DeviceEndpoint,
```

(continues on next page)

(continued from previous page)

```
  IN BOOLEAN                        IsNewTransfer,
  IN UINTN                          PollingInterval OPTIONAL,
  IN UINTN                          DataLength OPTIONAL,
  IN EFI_ASYNC_USB_TRANSFER_CALLBACK   InterruptCallBack OPTIONAL,
  IN VOID                           *Context OPTIONAL
  );
```

Parameters

This

A pointer to the *EFI_USB_IO_PROTOCOL* instance. Type EFI_USB_IO_PROTOCOL is defined in *USB I/O Protocol* .

DeviceEndpoint

The destination USB device endpoint to which the device request is being sent. DeviceEndpoint must be between 0x01 and 0x0F or between 0x81 and 0x8F, otherwise EFI_INVALID_PARAMETER is returned. If the endpoint is not an INTERRUPT endpoint, EFI_INVALID_PARAMETER is returned. The MSB of this parameter indicates the endpoint direction. The number “1” stands for an IN endpoint, and “0” stands for an OUT endpoint.

IsNewTransfer

If **TRUE**, a new transfer will be submitted to USB controller. If **FALSE**, the interrupt transfer is deleted from the device’s interrupt transfer queue. If **TRUE**, and an interrupt transfer exists for the target end point, then EFI_INVALID_PARAMETER is returned.

PollingInterval

Indicates the periodic rate, in milliseconds, that the transfer is to be executed. This parameter is required when IsNewTransfer is **TRUE**. The value must be between 1 to 255, otherwise EFI_INVALID_PARAMETER is returned. The units are in milliseconds.

DataLength

Specifies the length, in bytes, of the data to be received from the USB device. This parameter is only required when IsNewTransfer is **TRUE**.

Context

Data passed to the InterruptCallback function. This is an optional parameter and may be **NULL**.

InterruptCallback

The Callback function. This function is called if the asynchronous interrupt transfer is completed. This parameter is required when IsNewTransfer is **TRUE**. See **Related Definitions** for the definition of this type.

Related Definitions

```
typedef
EFI_STATUS
(EFIAPI * EFI_ASYNC_USB_TRANSFER_CALLBACK) (
  IN VOID               *Data,
  IN UINTN              DataLength,
  IN VOID               *Context,
  IN UINT32             Status
  );
```

Data

Data received or sent via the USB Asynchronous Transfer, if the transfer completed successfully.

DataLength

The length of Data received or sent via the Asynchronous Transfer, if transfer successfully completes.

Context

Data passed from *EFI_USB_IO_PROTOCOL.UsbAsyncInterruptTransfer()* request.

Status

Indicates the result of the asynchronous transfer.

Description

This function allows a USB device driver to communicate with a USB device with an Interrupt Transfer. Asynchronous Interrupt transfer is different than the other four transfer types because it is a nonblocking transfer. The interrupt endpoint is queried at a fixed rate, and the data transfer direction is always in the direction from the USB device towards the system.

If *IsNewTransfer* is **TRUE**, then an interrupt transfer is started at a fixed rate. The rate is specified by *PollingInterval*, the size of the receive buffer is specified by *DataLength*, and the callback function is specified by *InterruptCallback*. If *IsNewTransfer* is **TRUE**, and an interrupt transfer exists for the target end point, then *EFI_INVALID_PARAMETER* is returned.

If *IsNewTransfer* is **FALSE**, then the interrupt transfer is canceled.

Status Codes Returned

EFI_SUCCESS	The asynchronous USB transfer request has been successfully executed.
EFI_DEVICE_ERROR	The asynchronous USB transfer request failed. When an interrupt transfer exists for the target end point and a new transfer is requested, EFI_INVALID_PARAMETER is returned.

Examples

Below is an example of how an asynchronous interrupt transfer is used. The example shows how a USB Keyboard Device Driver can periodically receive data from interrupt endpoint.

```
EFI_USB_IO_PROTOCOL        *UsbIo;
EFI_STATUS                 Status;
USB_KEYBOARD_DEV           *UsbKeyboardDevice;
EFI_USB_INTERRUPT_CALLBACK *KeyboardHandle;

. . .
Status = UsbIo->UsbAsyncInterruptTransfer(
          UsbIo,
                         UsbKeyboardDevice->IntEndpointAddress,
                         TRUE,
                         UsbKeyboardDevice->IntPollingInterval,
                         8,
                         KeyboardHandler,
                         UsbKeyboardDevice
                         );
. . .

//
// The following is the InterruptCallback function. If there is
// any results got from Asynchronous Interrupt Transfer,
// this function will be called.
//
EFI_STATUS
KeyboardHandler(
```

(continues on next page)

(continued from previous page)

```
  IN VOID          *Data,
  IN UINTN         DataLength,
  IN VOID          *Context,
  IN UINT32        Result
  )
{
  USB_KEYBOARD_DEV *UsbKeyboardDevice;
  UINTN I;

  if(EFI_ERROR(Result))
  {
    //
    // Something error during this transfer,
    // just to some recovery work
    //
   . . .
   . . .
   return EFI_DEVICE_ERROR;
  }

  UsbKeyboardDevice = (USB_KEYBOARD_DEV *)Context;
  for(I = 0; I < DataLength; I++)
  {
    ParsedData(Data[I]);
    . . .
 }

 return EFI_SUCCESS;
}
```

17.2.9 EFI_USB_IO_PROTOCOL.UsbSyncInterruptTransfer()

Summary

This function is used to manage a USB device with an interrupt transfer pipe. The difference between *EFI_USB_IO_PROTOCOL.UsbAsyncInterruptTransfer()* and *UsbSyncInterruptTransfer()* is that the Synchronous interrupt transfer will only be executed one time. Once it returns, regardless of its status, the interrupt request will be deleted in the system.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USB_IO_SYNC_INTERRUPT_TRANSFER) (
  IN   EFI_USB_IO_PROTOCOL     *This,
  IN   UINT8                   DeviceEndpoint,
  IN OUT VOID                  *Data,
  IN OUT UINTN                 *DataLength,
  IN   UINTN                   Timeout,
  OUT  UINT32                  *Status
  );
```

Parameters

This

A pointer to the *EFI_USB_IO_PROTOCOL* instance. Type EFI_USB_IO_PROTOCOL is defined in *USB I/O Protocol* .

DeviceEndpoint

The destination USB device endpoint to which the device request is being sent. DeviceEndpoint must be between 0x01 and 0x0F or between 0x81 and 0x8F, otherwise EFI_INVALID_PARAMETER is returned. If the endpoint is not an INTERRUPT endpoint, EFI_INVALID_PARAMETER is returned. The MSB of this parameter indicates the endpoint direction. The number "1" stands for an IN endpoint, and "0" stands for an OUT endpoint.

Data

A pointer to the buffer of data that will be transmitted to USB device or received from USB device.

DataLength

On input, then size, in bytes, of the buffer Data. On output, the amount of data actually transferred.

Timeout

The time out, in milliseconds, for this transfer. If *Timeout* is 0, then the caller must wait for the function to be completed until *EFI_SUCCESS* or *EFI_DEVICE_ERROR* is returned. If the transfer is not completed in this time frame, then *EFI_TIMEOUT* is returned.

Status

This parameter indicates the USB transfer status.

Description

This function allows a USB device driver to communicate with a USB device through a synchronous interrupt transfer. The *UsbSyncInterruptTransfer()* differs from *EFI_USB_IO_PROTOCOL.UsbAsyncInterruptTransfer()* described in the previous section in that it is a blocking transfer request. The caller must wait for the function return, either successfully or unsuccessfully.

Status Codes Returned

EFI_SUCCESS	The sync interrupt transfer has been successfully executed.
EFI_INVALID_PARAMETER	The parameter DeviceEndpoint is not valid.
EFI_INVALID_PARAMETER	Data is **NULL**.
EFI_INVALID_PARAMETER	DataLength is **NULL**.
EFI_INVALID_PARAMETER	Status is **NULL**.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.
EFI_TIMEOUT	The transfer cannot be completed within Timeout timeframe.
EFI_DEVICE_ERROR	The transfer failed other than timeout, and the transfer status is returned in Status.

17.2.10 EFI_USB_IO_PROTOCOL.UsbIsochronousTransfer()

Summary

This function is used to manage a USB device with an isochronous transfer pipe. An Isochronous transfer is typically used to transfer streaming data.

Prototype

```
typedef
EFI_STATUS
(EFIAPI * EFI_USB_IO_ISOCHRONOUS_TRANSFER) (
  IN   EFI_USB_IO_PROTOCOL     *This,
```

(continues on next page)

(continued from previous page)

```
  IN   UINT8                    DeviceEndpoint,
  IN OUT VOID                   *Data,
  IN   UINTN                    DataLength,
  OUT  UINT32                   *Status
  );
```

Parameters

This

A pointer to the *EFI_USB_IO_PROTOCOL* instance. Type EFI_USB_IO_PROTOCOL is defined in *USB I/O Protocol* .

DeviceEndpoint

The destination USB device endpoint to which the device request is being sent. *DeviceEndpoint* must be between 0x01 and 0x0F or between 0x81 and 0x8F, otherwise EFI_INVALID_PARAMETER is returned. If the endpoint is not an ISOCHRONOUS endpoint, EFI_INVALID_PARAMETER is returned. The MSB of this parameter indicates the endpoint direction. The number "1" stands for an IN endpoint, and "0" stands for an OUT endpoint.

Data

A pointer to the buffer of data that will be transmitted to USB device or received from USB device.

DataLength

The size, in bytes, of the data buffer specified by Data.

Status

This parameter indicates the USB transfer status.

Description

This function allows a USB device driver to communicate with a USB device with an Isochronous Transfer. The type of transfer is different than the other types because the USB Bus Driver will not attempt to perform error recovery if transfer fails. If the USB transfer is completed successfully, then *EFI_SUCCESS* is returned. The isochronous transfer is designed to be completed within 1 USB frame time, if it cannot be completed, *EFI_TIMEOUT* is returned. If the transfer fails due to other reasons, then *EFI_DEVICE_ERROR* is returned and the detailed error status is returned in *Status*. If the data length exceeds the maximum payload per USB frame time, then it is this function's responsibility to divide the data into a set of smaller packets that fit into a USB frame time. If all the packets are transferred successfully, then *EFI_SUCCESS* is returned.

Status Codes Returned

EFI_SUCCESS	The isochronous transfer has been successfully executed.
EFI_INVALID_PARAMETER	The parameter DeviceEndpoint is not valid.
EFI_OUT_OF_RESOURCES	The request could not be completed due to a lack of resources.
EFI_TIMEOUT	The transfer cannot be completed within the 1 USB frame time.
EFI_DEVICE_ERROR	The transfer failed due to the reason other than timeout, The error status is returned in Status.
EFI_UNSUPPORTED	The implementation doesn't support an Isochronous transfer function.

17.2.11 EFI_USB_IO_PROTOCOL.UsbAsyncIsochronousTransfer()

Summary

This function is used to manage a USB device with an isochronous transfer pipe. An asynchronous Isochronous transfer is a nonblocking USB isochronous transfer.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USB_IO_ASYNC_ISOCHRONOUS_TRANSFER) (
  IN EFI_USB_IO_PROTOCOL              *This,
  IN UINT8                            DeviceEndpoint,
  IN OUT VOID                         *Data,
  IN UINTN                            DataLength,
  IN EFI_ASYNC_USB_TRANSFER_CALLBACK   IsochronousCallBack,
  IN VOID                             *Context OPTIONAL
  );
```

Parameters

This
A pointer to the *EFI_USB_IO_PROTOCOL* instance. Type EFI_USB_IO_PROTOCOL is defined in *USB I/O Protocol* .

DeviceEndpoint
The destination USB device endpoint to which the device request is being sent. *DeviceEndpoint* must be between 0x01 and 0x0F or between 0x81 and 0x8F, otherwise *EFI_INVALID_PARAMETER* is returned. If the endpoint is not an ISOCHRONOUS endpoint, *EFI_INVALID_PARAMETER* is returned. The MSB of this parameter indicates the endpoint direction. The number "1" stands for an IN endpoint, and "0" stands for an OUT endpoint.

Data
A pointer to the buffer of data that will be transmitted to USB device or received from USB device.

DataLength
Specifies the length, in bytes, of the data to be sent to or received from the USB device.

Context
Data passed to the IsochronoisCallback() in Protocols_USB_Support.rst function. This is an optional parameter and may be **NULL**.

IsochronousCallback
The *IsochronousCallback()* function. This function is called if the requested isochronous transfer is completed. See the **Related Definitions** section of the *EFI_USB_IO_PROTOCOL.UsbAsyncInterruptTransfer()* function description.

Description

This is an asynchronous type of USB isochronous transfer. If the caller submits a USB isochronous transfer request through this function, this function will return immediately. When the isochronous transfer completes, the Isochronois-Callback() function will be triggered, the caller can know the transfer results. If the transfer is successful, the caller can get the data received or sent in this callback function.

Status Codes Returned

EFI_SUCCESS	The asynchronous isochronous transfer has been successfully submitted to the system.

continues on next page

Table 17.18 – continued from previous page

EFI_INVALID_PARAMETER	The parameter DeviceEndpoint is not valid.
EFI_OUT_OF_RESOURCES	The request could not be submitted due to a lack of resources.
EFI_UNSUPPORTED	The implementation doesn't support an asynchronous Isochronous transfer function.

17.2.12 EFI_USB_IO_PROTOCOL.UsbGetDeviceDescriptor()

Summary

Retrieves the USB Device Descriptor.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USB_IO_GET_DEVICE_DESCRIPTOR) (
  IN EFI_USB_IO_PROTOCOL             *This,
  OUT EFI_USB_DEVICE_DESCRIPTOR      *DeviceDescriptor
  );
```

Parameters

This

A pointer to the *EFI_USB_IO_PROTOCOL* instance. Type EFI_USB_IO_PROTOCOL is defined in *USB I/O Protocol* .

DeviceDescriptor

A pointer to the caller allocated USB Device Descriptor. See **Related Definitions** for a detailed description.

Related Definitions

```
//
// See USB1.1 for detail description.
//
typedef struct {
  UINT8    Length;
  UINT8    DescriptorType;
  UINT16   BcdUSB;
  UINT8    DeviceClass;
  UINT8    DeviceSubClass;
  UINT8    DeviceProtocol;
  UINT8    MaxPacketSize0;
  UINT16   IdVendor;
  UINT16   IdProduct;
  UINT16   BcdDevice;
  UINT8    StrManufacturer;
  UINT8    StrProduct;
  UINT8    StrSerialNumber;
  UINT8    NumConfigurations;
} EFI_USB_DEVICE_DESCRIPTOR;
```

Description

This function is used to retrieve information about USB devices. This information includes the device class, subclass, and the number of configurations the USB device supports. If *DeviceDescriptor* is **NULL**, then

EFI_INVALID_PARAMETER is returned. If the USB device descriptor is not found, then *EFI_NOT_FOUND* is returned. Otherwise, the device descriptor is returned in *DeviceDescriptor*, and *EFI_SUCCESS* is returned.

Status Codes Returned

EFI_SUCCESS	The device descriptor was retrieved successfully.
EFI_INVALID_PARAMETER	DeviceDescriptor is **NULL**.
EFI_NOT_FOUND	The device descriptor was not found. The device may not be configured.

17.2.13 EFI_USB_IO_PROTOCOL.UsbGetConfigDescriptor()

Summary

Retrieves the USB Device Configuration Descriptor.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USB_IO_GET_CONFIG_DESCRIPTOR) (
  IN EFI_USB_IO_PROTOCOL                  *This,
  OUT EFI_USB_CONFIG_DESCRIPTOR           *ConfigurationDescriptor
  );
```

Parameters

This

A pointer to the *EFI_USB_IO_PROTOCOL* instance. Type EFI_USB_IO_PROTOCOL is defined in *USB I/O Protocol* .

ConfigurationDescriptor

A pointer to the caller allocated USB Active Configuration Descriptor. See **Related Definitions** for a detailed description.

Related Definitions

```
//
// See USB1.1 for detail description.
//
typedef struct {
  UINT8    Length;
  UINT8    DescriptorType;
  UINT16   TotalLength;
  UINT8    NumInterfaces;
  UINT8    ConfigurationValue;
  UINT8    Configuration;
  UINT8    Attributes;
  UINT8    MaxPower;
} EFI_USB_CONFIG_DESCRIPTOR;
```

Description

This function is used to retrieve the active configuration that the USB device is currently using. If *ConfigurationDescriptor* is **NULL**, then *EFI_INVALID_PARAMETER* is returned. If the USB controller does not contain an active configuration, then *EFI_NOT_FOUND* is returned. Otherwise, the active configuration is returned in *ConfigurationDescriptor*, and *EFI_SUCCESS* is returned.

Status Codes Returned

EFI_SUCCESS	The active configuration descriptor was retrieved successfully.
EFI_INVALID_PARAMETER	ConfigurationDescriptor is **NULL**.
EFI_NOT_FOUND	An active configuration descriptor cannot be found. The device may not be configured.

17.2.14 EFI_USB_IO_PROTOCOL.UsbGetInterfaceDescriptor()

Summary

Retrieves the Interface Descriptor for a USB Device Controller. As stated earlier, an interface within a USB device is equivalently to a USB Controller within the current configuration.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USB_IO_GET_INTERFACE_DESCRIPTOR) (
  IN EFI_USB_IO_PROTOCOL             *This,
  OUT EFI_USB_INTERFACE_DESCRIPTOR   *InterfaceDescriptor
  );
```

Parameters

This

A pointer to the *EFI_USB_IO_PROTOCOL* instance. Type EFI_USB_IO_PROTOCOL is defined in *USB I/O Protocol* .

InterfaceDescriptor

A pointer to the caller allocated USB Interface Descriptor within the configuration setting. See **Related Definitions** for a detailed description.

Related Definitions

```
//
  // See USB1.1 for detail description.
  //
  typedef struct {
    UINT8  Length;
    UINT8  DescriptorType;
    UINT8  InterfaceNumber;
    UINT8  AlternateSetting;
    UINT8  NumEndpoints;
    UINT8  InterfaceClass;
    UINT8  InterfaceSubClass;
    UINT8  InterfaceProtocol;
    UINT8  Interface;
  }  EFI_USB_INTERFACE_DESCRIPTOR;
```

Description

This function is used to retrieve the interface descriptor for the USB controller. If *InterfaceDescriptor* is **NULL**, then *EFI_INVALID_PARAMETER* is returned. If the USB controller does not contain an interface descriptor, then *EFI_NOT_FOUND* is returned. Otherwise, the interface descriptor is returned in *InterfaceDescriptor*, and *EFI_SUCCESS* is returned.

Status Codes Returned

EFI_SUCCESS	The interface descriptor retrieved successfully.
EFI_INVALID_PARAMETER	InterfaceDescriptor is **NULL.**
EFI_NOT_FOUND	The interface descriptor cannot be found. The device may not be correctly configured.

17.2.15 EFI_USB_IO_PROTOCOL.UsbGetEndpointDescriptor()

Summary

Retrieves an Endpoint Descriptor within a USB Controller.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USB_IO_GET_ENDPOINT_DESCRIPTOR) (
  IN EFI_USB_IO_PROTOCOL           *This,
  IN UINT8                         EndpointIndex,
  OUT EFI_USB_ENDPOINT_DESCRIPTOR  *EndpointDescriptor
  );
```

Parameters

This
A pointer to the *EFI_USB_IO_PROTOCOL* instance. Type EFI_USB_IO_PROTOCOL is defined in *USB I/O Protocol* .

EndpointIndex
Indicates which endpoint descriptor to retrieve. The valid range is 0..15.

EndpointDescriptor
A pointer to the caller allocated USB Endpoint Descriptor of a USB controller. See **Related Definitions** for a detailed description.

Related Definitions

```
//
// See USB1.1 for detail description.
//
typedef struct {
  UINT8    Length;
  UINT8    DescriptorType;
  UINT8    EndpointAddress;
  UINT8    Attributes;
  UINT16   MaxPacketSize;
  UINT8    Interval;
}  EFI_USB_ENDPOINT_DESCRIPTOR;
```

Description

This function is used to retrieve an endpoint descriptor within a USB controller. If *EndpointIndex* is not in the range 0..15, then *EFI_INVALID_PARAMETER* is returned. If *EndpointDescriptor* is **NULL**, then *EFI_INVALID_PARAMETER* is returned. If the endpoint specified by *EndpointIndex* does not exist within the USB controller, then *EFI_NOT_FOUND* is returned. Otherwise, the endpoint descriptor is returned in *EndpointDescriptor*, and *EFI_SUCCESS* is returned.

Status Codes Returned

EFI_SUCCESS	The endpoint descriptor was retrieved successfully.
EFI_INVALID_PARAMETER	EndpointIndex is not valid.
EFI_INVALID_PARAMETER	EndpointDescriptor is **NULL**.
EFI_NOT_FOUND	The endpoint descriptor cannot be found. The device may not be correctly configured.

Examples

The following code fragment shows how to retrieve all the endpoint descriptors from a USB controller.

```
EFI_USB_IO_PROTOCOL             *UsbIo;
EFI_USB_INTERFACE_DESCRIPTOR    InterfaceDesc;
EFI_USB_ENDPOINT_DESCRIPTOR     EndpointDesc;
UINTN                           Index;

Status = UsbIo->GetInterfaceDescriptor (
         UsbIo,
         &InterfaceDesc
         );

. . .
for(Index = 0; Index < InterfaceDesc.NumEndpoints; Index++) {
 Status = UsbIo->GetEndpointDescriptor(
          UsbIo,
          Index,
          &EndpointDesc
          );

. . .
}
```

17.2.16 EFI_USB_IO_PROTOCOL.UsbGetStringDescriptor()

Summary

Retrieves a string stored in a USB Device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USB_IO_GET_STRING_DESCRIPTOR) (
  IN EFI_USB_IO_PROTOCOL        *This,
  IN UINT16                     LangID,
  IN UINT8                      StringID,
  OUT CHAR16                    **String
  );
```

Parameters

This

A pointer to the *EFI_USB_IO_PROTOCOL* instance. Type EFI_USB_IO_PROTOCOL is defined in *USB I/O Protocol* .

LangID

The Language ID for the string being retrieved. See the *EFI_USB_IO_PROTOCOL.UsbGetSupportedLanguages()* function description for a more detailed description.

StringID

The ID of the string being retrieved.

String

A pointer to a buffer allocated by this function with *EFI_BOOT_SERVICES.AllocatePool()* to store the string. If this function returns EFI_SUCCESS, it stores the string the caller wants to get. The caller should release the string buffer with *EFI_BOOT_SERVICES.FreePool()* after the string is not used any more.

Description

This function is used to retrieve strings stored in a USB device. The string to retrieve is identified by a language and an identifier. The language is specified by *LangID*, and the identifier is specified by *StringID*. If the string is found, it is returned in *String*, and *EFI_SUCCESS* is returned. If the string cannot be found, then *EFI_NOT_FOUND* is returned. The string buffer is allocated by this function with *AllocatePool()*. The caller is responsible for calling *FreePool()* for *String* when it is no longer required.

Status Codes Returned

EFI_SUCCESS	The string was retrieved successfully.
EFI_NOT_FOUND	The string specified by LangID and StringID was not found.
EFI_OUT_OF_RESOURCES	There are not enough resources to allocate the return buffer String.

17.2.17 EFI_USB_IO_PROTOCOL.UsbGetSupportedLanguages()

Summary

Retrieves all the language ID codes that the USB device supports.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USB_IO_GET_SUPPORTED_LANGUAGES) (
  IN EFI_USB_IO_PROTOCOL         *This,
  OUT UINT16                     **LangIDTable,
  OUT UINT16                     *TableSize
  );
```

Parameters

This

A pointer to the *EFI_USB_IO_PROTOCOL* instance. Type EFI_USB_IO_PROTOCOL is defined in *USB I/O Protocol* .

LangIDTable

Language ID for the string the caller wants to get. This is a 16-bit ID defined by Microsoft. This buffer pointer is allocated and maintained by the USB Bus Driver, the caller should not modify its contents.

TableSize

The size, in bytes, of the table *LangIDTable*.

Description

Retrieves all the language ID codes that the USB device supports.

Status Codes Returned

EFI_SUCCESS	The support languages were retrieved successfully.

17.2.18 EFI_USB_IO_PROTOCOL.UsbPortReset()

Summary

Resets and reconfigures the USB controller. This function will work for all USB devices except USB Hub Controllers.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USB_IO_PORT_RESET) (
  IN EFI_USB_IO_PROTOCOL         *This
  );
```

Parameters

This
A pointer to the *EFI_USB_IO_PROTOCOL* instance. Type EFI_USB_IO_PROTOCOL is defined in *USB I/O Protocol* .

Description

This function provides a reset mechanism by sending a RESET signal from the parent hub port. A reconfiguration process will happen (that includes setting the address and setting the configuration). This reset function does not change the bus topology. A USB hub controller cannot be reset using this function, because it would impact the downstream USB devices. So if the controller is a USB hub controller, then *EFI_INVALID_PARAMETER* is returned.

Status Codes Returned

EFI_SUCCESS	The USB controller was reset.
EFI_INVALID_PARAMETER	If the controller specified by *This* is a USB hub.
EFI_DEVICE_ERROR	An error occurred during the reconfiguration process.

17.3 USB Function Protocol

This section describes the USB Function Protocol, enabling a USB Function device with a UEFI driver that implements the protocol to communicate with a a USB Host device.

The USB Function Protocol provides an I/O abstraction for a USB Controller operating in Function mode (also commonly referred to as Device, Peripheral, or Target mode) and the mechanisms by which the USB Function can communicate with the USB Host. It is used by other UEFI drivers or applications to perform data transactions and basic USB controller management over a USB Function port.

This simple protocol only supports USB 2.0 bulk transfers on systems with a single configuration and a single interface. It does not support isochronous or interrupt transfers, alternate interfaces, or USB 3.0 functionality. Future revisions of this protocol may support these or additional features.

17.3.1 EFI_USBFN_IO_PROTOCOL

Summary

Provides basic data transactions and basic USB controller management for a USB Function port.

GUID

```
// {32D2963A-FE5D-4f30-B633-6E5DC55803CC}
  #define EFI_USBFN_IO_PROTOCOL_GUID \
    {0x32d2963a, 0xfe5d, 0x4f30,\
      {0xb6, 0x33, 0x6e, 0x5d, 0xc5, 0x58, 0x3, 0xcc}};
```

Revision Number

```
#define EFI_USBFN_IO_PROTOCOL_REVISION 0x00010001
```

Protocol Interface Structure

```
typedef struct _EFI_USBFN_IO_PROTOCOL {
  UINT32                                   Revision;
  EFI_USBFN_IO_DETECT_PORT                 DetectPort;
  EFI_USBFN_IO_CONFIGURE_ENABLE_ENDPOINTS  \

  EFI_USBFN_IO_GET_ENDPOINT_STALL_STATE    \
                                           GetEndpointStallState;
  EFI_USBFN_IO_SET_ENDPOINT_STALL_STATE    \
                                           SetEndpointStallState;
  EFI_USBFN_IO_EVENTHANDLER                EventHandler;
  EFI_USBFN_IO_TRANSFER                    Transfer;
  EFI_USBFN_IO_GET_MAXTRANSFER_SIZE        \
                                           GetMaxTransferSize;
  EFI_USBFN_IO_ALLOCATE_TRANSFER_BUFFER    AllocateTransferBuffer;
  EFI_USBFN_IO_FREE_TRANSFER_BUFFER        FreeTransferBuffer;

  EFI_USBFN_IO_START_CONTROLLER            StartController;
  EFI_USBFN_IO_STOP_CONTROLLER             StopController;

  EFI_USBFN_IO_SET_ENDPOINT_POLICY         SetEndpointPolicy;
  EFI_USBFN_IO_GET_ENDPOINT_POLICY         GetEndpointPolicy;
}  EFI_USBFN_IO_PROTOCOL;
```

Parameters

Revision

The revision to which the *EFI_USBFN_IO_PROTOCOL* adheres. All future revisions must be backwards compatible. If a future version is not backwards compatible, a different GUID must be used.

DetectPort

Returns information about the USB port type. See **Related Definitions** *EFI_USBFN_IO_PROTOCOL.DetectPort()*, for more details.

ConfigureEnableEndpoints
Initializes all endpoints based on supplied device and configuration descriptors. Enables the device by setting the run/stop bit.

GetEndpointMaxPacketSize
Returns the maximum packet size of the specified endpoint.

GetDeviceInfo
Returns device specific information based on the supplied identifier as a Unicode string.

GetVendorIdProductId
Returns the vendor-id and product-id of the device.

AbortTransfer
Aborts the transfer on the specified endpoint.

GetEndpointStallState
Returns the stall state on the specified endpoint.

SetEndpointStallState
Sets or clears the stall state on the specified endpoint.

EventHandler
This function is called repeatedly to get information on USB bus states, receive-completion and transmit-completion events on the endpoints, and notification on setup packet on endpoint 0.

Transfer
This function handles transferring data to or from the host on the specified endpoint, depending on the direction specified.

GetMaxTransferSize
The maximum supported transfer size in bytes.

AllocateTransferBuffer
Allocates a transfer buffer of the specified size that satisfies the controller requirements.

FreeTransferBuffer
Deallocates the memory allocated for the transfer buffer by *EFI_USBFN_IO_PROTOCOL.AllocateTransferBuffer()* function.

StartController
This function initializes the hardware and the internal data structures. The port must not be activated by this function.

StopController
This function disables the device by deactivating the port.

SetEndpointPolicy
This function sets the configuration policy for the specified non-control endpoint. There are a few calling restrictions for this function. See the *EFI_USBFN_IO_PROTOCOL.SetEndpointPolicy()* function definition for more details.

GetEndpointPolicy
This functions retrieves the configuration policy for the specified non-control endpoint.

Description

This protocol provides basic data transactions and USB controller management for a USB Function port. It provides a lightweight communication mechanism between a USB Host and a USB Function in the UEFI environment.

Like other UEFI device drivers, the entry point for a USB function driver attaches *EFI_DRIVER_BINDING_PROTOCOL* to image handle of *EFI_USBFN_IO_PROTOCOL* driver.

The driver binding protocol contains three services, Supported, Start and Stop.

The *Supported* function must test to see if this driver supports a given controller.

The *Start* function must supply power to the USB controller if needed, initialize hardware and internal data structures, and then return. The port must not be activated by this function.

The Stop function must disable the USB controller and power it off if needed.

17.3.2 EFI_USBFN_IO_PROTOCOL.DetectPort()

Summary

Returns information about what USB port type was attached.

Prototype

```
typedef
EFI_STATUS
(EFIAPI * EFI_USBFN_IO_DETECT_PORT) (
  IN EFI_USBFN_IO_PROTOCOL         *This,
  OUT EFI_USBFN_PORT_TYPE          *PortType
  );
```

Parameters

This
A pointer to the *EFI_USBFN_IO_PROTOCOL* instance.

PortType
Returns the USB port type. Refer to the **Related Definitions** for this function below for details.

Description

Returns information about the USB port type attached. Refer to the **Related Definitions** below for further details.

Status Codes Returned

EFI_SUCCESS	The function returned successfully.
EFI_INVALID_PARAMETER	A parameter is invalid.
EFI_DEVICE_ERROR	The physical device reported an error.
EFI_NOT_READY	The physical device is busy or not ready to process this request or there is no USB port attached to the device

Related Definitions

```
typedef enum _EFI_USBFN_PORT_TYPE {
  EfiUsbUnknownPort = 0,
  EfiUsbStandardDownstreamPort,
  EfiUsbChargingDownstreamPort,
  EfiUsbDedicatedChargingPort,
  EfiUsbInvalidDedicatedChargingPort
}  EFI_USBFN_PORT_TYPE;
```

Unknown Port
Driver internal default port type, this is never returned by the driver with a success status code.

Standard Downstream Port
Standard USB host; refer to *USB Battery Charging Specification, Revision 1.2* in Appendix Q.1 for details and the link.

Charging Downstream Port
Standard USB host with special charging properties; refer to *USB Battery Charging Specification, Revision 1.2* in Appendix Q.1 ` for the details and link.

Dedicated Charging Port
A wall-charger, not USB host; refer to *USB Battery Charging Specification, Revision 1.2,* in Appendix Q.1 for details and the link.

Invalid Dedicated Charging Port -
Neither a USB host nor a dedicated charging port as defined by the *USB Battery Charging Specification, Revision 1.2.* in Appendix Q.1 for details and the link.) An example is a USB charger that raises the voltages on D+/D-, causing the charger to look like an SDP even though it will never issue a setup packet to the upstream facing port.

17.3.3 EFI_USBFN_IO_PROTOCOL.ConfigureEnableEndpoints()

Summary

Configures endpoints based on supplied device and configuration descriptors.

Prototype

```
typedef
EFI_STATUS
(EFIAPI * EFI_USBFN_IO_CONFIGURE_ENABLE_ENDPOINTS) (
  IN EFI_USBFN_IO_PROTOCOL          *This,
  IN EFI_USB_DEVICE_INFO            *DeviceInfo
  );
```

Parameters

This
A pointer to the *EFI_USBFN_IO_PROTOCOL* instance.

DeviceInfo
A pointer to *EFI_USBFN_DEVICE_INFO* instance. Refer to the **Related Definitions** for this function below for details.

Description

Assuming that the hardware has already been initialized, this function configures the endpoints using the device information supplied by *DeviceInfo*, activates the port, and starts receiving USB events.

This function must ignore the *bMaxPacketSize0* field of the Standard Device Descriptor and the *wMaxPacketSize* field of the Standard Endpoint Descriptor that are made available through *DeviceInfo*.

Status Codes Returned

EFI_SUCCESS	The function returned successfully.
EFI_INVALID_PARAMETER	A parameter is invalid.
EFI_DEVICE_ERROR	The physical device reported an error.
EFI_NOT_READY	The physical device is busy or not ready to process this request.
EFI_OUT_OF_RESOURCES	The request could not be completed due to lack of resources.

Related Definitions

```
typedef struct {
  EFI_USB_INTERFACE_DESCRIPTOR   *InterfaceDescriptor;
  EFI_USB_ENDPOINT_DESCRIPTOR    **EndpointDescriptorTable;
}  EFI_USB_INTERFACE_INFO;

typedef struct {
  EFI_USB_CONFIG_DESCRIPTOR      *ConfigDescriptor*;
  EFI_USB_INTERFACE_INFO         **InterfaceInfoTable*;
}  EFI_USB_CONFIG_INFO;

typedef struct {
  EFI_USB_DEVICE_DESCRIPTOR      *DeviceDescriptor*;
  EFI_USB_CONFIG_INFO            **ConfigInfoTable*;
}  EFI_USB_DEVICE_INFO;
```

USB_DEVICE_DESCRIPTOR, USB_CONFIG_DESCRIPTOR, USB_INTERFACE_DESCRIPTOR, and USB_ENDPOINT_DESCRIPTOR are defined in Section *USB I/O Protocol*.

17.3.4 EFI_USBFN_IO_PROTOCOL.GetEndpointMaxPacketSize()

Summary

Returns the maximum packet size of the specified endpoint type for the supplied bus speed.

Prototype

```
typedef
EFI_STATUS
(EFIAPI * EFI_USBFN_IO_GET_ENDPOINT_MAXPACKET_SIZE) (
  IN EFI_USBFN_IO_PROTOCOL         *This,
  IN EFI_USB_ENDPOINT_TYPE         EndpointType,
  IN EFI_USB_BUS_SPEED             BusSpeed,
  OUT UINT16                       *MaxPacketSize
  );
```

Parameters

This

A pointer to the *EFI_USBFN_IO_PROTOCOL* instance.

EndpointType

Endpoint type as defined as *EFI_USB_ENDPOINT_TYPE* in the **Related Definitions** for this function below for details.

BusSpeed

Bus speed as defined as *EFI_USB_BUS_SPEED* in the **Related Definitions** for the *EventHandle* function for details.

MaxPacketSize

The maximum packet size, in bytes, of the specified endpoint type.

Description

Returns the maximum packet size of the specified endpoint type for the supplied bus speed. If the *BusSpeed* is *UsbBusSpeedUnknown*, the maximum speed the underlying controller supports is assumed.

This protocol currently does not support isochronous or interrupt transfers. Future revisions of this protocol may eventually support it.

Status Codes Returned

EFI_SUCCESS	The function returned successfully.
EFI_INVALID_PARAMETER	A parameter is invalid.
EFI_DEVICE_ERROR	The physical device reported an error.
EFI_NOT_READY	The physical device is busy or not ready to process this request.

Related Definitions

```
typedef enum _EFI_USB_ENDPOINT_TYPE
{
  UsbEndpointControl          = 0x00,
  // UsbEndpointIsochronous  = 0x01,
  UsbEndpointBulk             = 0x02,
  // UsbEndpointInterrupt    = 0x03
} EFI_USB_ENDPOINT_TYPE;
```

17.3.5 EFI_USBFN_IO_PROTOCOL.GetDeviceInfo()

Summary

Returns device specific information based on the supplied identifier as a Unicode string.

Prototype

```
typedef
EFI_STATUS
(EFIAPI * EFI_USBFN_IO_GET_DEVICE_INFO) (
  IN EFI_USBFN_IO_PROTOCOL           *This,
  IN EFI_USBFN_DEVICE_INFO_ID        Id,
  IN OUT UINTN                       *BufferSize,
  OUT VOID                           *Buffer OPTIONAL
  );
```

Parameters

This

A pointer to the *EFI_USBFN_IO_PROTOCOL* instance.

Id

The requested information id. Refer to the **Related Definitions** for this function below for details.

BufferSize

On input, the size of the *Buffer* in bytes. On output, the amount of data returned in *Buffer* in bytes.

Buffer

A pointer to a buffer to return the requested information as a Unicode string.

Description

Returns device specific information based on the supplied identifier as a Unicode string. If the supplied *Buffer* isn't large enough, or is **NULL**, the method fails with *EFI_BUFFER_TOO_SMALL* and the required size is returned through *BufferSize*. All returned strings are in Unicode format.

An *Id* of *EfiUsbDeviceInfoUnknown* is treated as an invalid parameter.

Status Codes Returned

EFI_SUCCESS	The function returned successfully.
EFI_INVALID_PARAMETER	One or more of the following conditions is **TRUE**: • BufferSize is **NULL**. • BufferSize[1] is not 0 and Buffer is **NULL**. • Id in invalid.
EFI_DEVICE_ERROR	The physical device reported an error.
EFI_NOT_READY	The physical device is busy or not ready to process this request.
EFI_BUFFER_TOO_SMALL	The buffer is too small to hold the buffer.
	[1]BufferSize has been updated with the size needed to hold the request string.

Related Definitions

```
typedef enum _EFI_USBFN_DEVICE_INFO_ID
{
  EfiUsbDeviceInfoUnknown = 0,
  EfiUsbDeviceInfoSerialNumber,
  EfiUsbDeviceInfoManufacturerName,
  EfiUsbDeviceInfoProductName
}  EFI_USBFN_DEVICE_INFO_ID;
```

17.3.6 EFI_USBFN_IO_PROTOCOL.GetVendorIdProductId()

Summary

Returns the vendor-id and product-id of the device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI * EFI_USBFN_IO_GET_VENDOR_ID_PRODUCT_ID) (
  IN EFI_USBFN_IO_PROTOCOL       *This,
  OUT UINT16                     *Vid,
  OUT UINT16                     *Pid
  );
```

Parameters

This

A pointer to the *EFI_USBFN_IO_PROTOCOL* instance.

Vid

Returned vendor-id of the device.

Pid

Returned product-id of the device.

Description

Returns vendor-id and product-id of the device.

Status Codes Returned

EFI_SUCCESS	The function returned successfully.
EFI_INVALID_PARAMETER	A parameter is invalid.
EFI_NOT_FOUND	Unable to return the vendor-id or the product-id

Related Definitions

Vendor IDs (VIDs) are 16-bit numbers that represent the device's vendor company and are assigned and maintained by the USB-IF. Product IDs (PIDs) are 16-bit numbers assigned by each vendor to the device.

17.3.7 EFI_USBFN_IO_PROTOCOL.AbortTransfer()

Summary

Aborts the transfer on the specified endpoint.

Prototype

```
typedef
EFI_STATUS
(EFIAPI * EFI_USBFN_IO_ABORT_TRANSFER) (
  IN EFI_USBFN_IO_PROTOCOL         *This,
  IN UINT8                         EndpointIndex,
  IN EFI_USBFN_ENDPOINT_DIRECTION  Direction
  );
```

Parameters

This
A pointer to the *EFI_USBFN_IO_PROTOCOL* instance.

EndpointIndex
Indicates the endpoint on which the ongoing transfer needs to be canceled.

Direction
Direction of the endpoint. Refer to the **Related Definitions** for this function (below) for details.

Description

Aborts the transfer on the specified endpoint. This function should fail with *EFI_INVALID_PARAMETER* if the specified direction is incorrect for the endpoint.

Status Codes Returned

EFI_SUCCESS	The function returned successfully.
EFI_INVALID_PARAMETER	A parameter is invalid.
EFI_DEVICE_ERROR	The physical device reported an error.
EFI_NOT_READY	The physical device is busy or not ready to process this request.

Related Definitions

```
typedef enum _EFI_USBFN_ENDPOINT_DIRECTION
{
  EfiUsbEndpointDirectionHostOut  = 0,
  EfiUsbEndpointDirectionHostIn,
```

(continues on next page)

(continued from previous page)

```
  EfiUsbEndpointDirectionDeviceTx = EfiUsbEndpointDirectionHostIn,
  EfiUsbEndpointDirectionDeviceRx = EfiUsbEndpointDirectionHostOut
} EFI_USBFN_ENDPOINT_DIRECTION;
```

17.3.8 EFI_USBFN_IO_PROTOCOL.GetEndpointStallState()

Summary

Returns the stall state on the specified endpoint.

Prototype

```
typedef
EFI_STATUS
(EFIAPI * EFI_USBFN_IO_GET_ENDPOINT_STALL_STATE) (
  IN EFI_USBFN_IO_PROTOCOL              *This,
  IN UINT8                              EndpointIndex,
  IN EFI_USBFN_ENDPOINT_DIRECTION       Direction,
  IN OUT BOOLEAN                        *State
  );
```

Parameters

This

A pointer to the *EFI_USBFN_IO_PROTOCOL* instance.

EndpointIndex

Indicates the endpoint.

Direction

Direction of the endpoint. Refer to the **Related Definitions** for details see *EFI_USBFN_IO_PROTOCOL.AbortTransfer()* .

State

Boolean, true value indicates that the endpoint is in a stalled state, false otherwise.

Description

Returns the stall state on the specified endpoint. This function would fail with *EFI_INVALID_PARAMETER* if the specified direction is incorrect for the endpoint.

Status Codes Returned

EFI_SUCCESS	The function returned successfully.
EFI_INVALID_PARAMETER	A parameter is invalid.
EFI_DEVICE_ERROR	The physical device reported an error.
EFI_NOT_READY	The physical device is busy or not ready to process this request.

17.3.9 EFI_USBFN_IO_PROTOCOL.SetEndpointStallState()

Summary

Sets or clears the stall state on the specified endpoint.

Prototype

```
typedef
EFI_STATUS
(EFIAPI * EFI_USBFN_IO_SET_ENDPOINT_STALL_STATE) (
  IN EFI_USBFN_IO_PROTOCOL              *This,
  IN UINT8                              EndpointIndex,
  IN EFI_USBFN_ENDPOINT_DIRECTION       Direction,
  IN BOOLEAN                            State
  );
```

Parameters

This

A pointer to the *EFI_USBFN_IO_PROTOCOL* instance.

EndpointIndex

Indicates the endpoint.

Direction

Direction of the endpoint. Refer to the **Related Definitions** for the *EFI_USBFN_IO_PROTOCOL.ABORTTRANSFER()* function for details.

State

Requested stall state on the specified endpoint. **TRUE** value causes the endpoint to stall; **FALSE** value clears an existing stall.

Description

Sets or clears the stall state on the specified endpoint. This function would fail with *EFI_INVALID_PARAMETER* if the specified direction is incorrect for the endpoint.

Status Codes Returned

EFI_SUCCESS	The function returned successfully.
EFI_INVALID_PARAMETER	A parameter is invalid.
EFI_DEVICE_ERROR	The physical device reported an error.
EFI_NOT_READY	The physical device is busy or not ready to process this request.

17.3.10 EFI_USBFN_IO_PROTOCOL.EventHandler()

Summary

This function is called repeatedly to get information on USB bus states, receive-completion and transmit-completion events on the endpoints, and notification on setup packet on endpoint 0.

Prototype

```
typedef
EFI_STATUS
(EFIAPI * EFI_USBFN_IO_EVENTHANDLER) (
  IN EFI_USBFN_IO_PROTOCOL           *This,
  OUT EFI_USBFN_MESSAGE              *Message,
  IN OUT UINTN                       *PayloadSize,
  OUT EFI_USBFN_MESSAGE_PAYLOAD      *Payload
  );
```

Parameters

This

A pointer to the *EFI_USBFN_IO_PROTOCOL* instance.

Message

Indicates the event that initiated this notification. Refer to the **Related Definitions** for this function (below) for all possible types.

PayloadSize

On input, the size of the memory pointed by *Payload*. On output, the amount of data returned in *Payload*.

Payload

A pointer to *EFI_USBFN_MESSAGE_PAYLOAD* instance to return additional payload for current message. Refer to the **Related Definitions** for this function (below) for details on the type.

Description

This function is called repeatedly to get information on USB bus states, receive-completion and transmit-completion events on the endpoints, and notification on setup packet on endpoint 0. A class driver must call *EFI_USBFN_IO_PROTOCOL.EventHandler()* repeatedly to receive updates on the transfer status and number of bytes transferred on various endpoints. Refer to Figure *Sequence of Operations with Endpoint Policy Changes* for details.

A few messages have an associated payload that is returned in the supplied buffer. The following table describes various messages and their payload:

Table 17.33: Payload Associated Messages and Descriptions

Message	**Payload**	**Description**
EfiUsbMsgSetupPacket	EFI_USB_DEVICE_REQUEST	SETUP packet was received.
EfiUsbMsgEndpointStatusChangedRx	EFI_USBFN_TRANSFER_RESULT	Some of the requested data has been transmitted to the host. It is the responsibility of the class driver to determine if any remaining data needs to be re-sent. The *Buffer* supplied to EFI_USBFN_IO_PROTOCOL.Transfer().must be same as the Buffer field of the payload.

continues on next page

Table 17.33 – continued from previous page

EfiUsbMsgEndpointStatusChangedTx	EFI_USBFN_TRANSFER_RESULT	Some of the requested data has been received from the host. It is the responsibility of the class driver to determine if it needs to wait for any remaining data. The Buffer supplied to EFI_USBFN_IO_PROTOCOL.Transfer() must be same as the Buffer field of the payload.
EfiUsbMsgBusEventReset	None	A RESET bus event was signaled.
EfiUsbMsgBusEventDetach	None	A DETACH bus event was signaled.
EfiUsbMsgBusEventAttach	None	An ATTACH bus event was signaled.
EfiUsbMsgBusEventSuspend	None	A SUSPEND bus event was signaled.
EfiUsbMsgBusEventResume	None	A RESUME bus event was signaled.
EfiUsbMsgBusEventSpeed	EFI_USB_BUS_SPEED	A Bus speed update was signaled.

Status Codes Returned

EFI_SUCCESS	The function returned successfully.
EFI_INVALID_PARAMETE	A parameter is invalid.
EFI_DEVICE_ERROR	The physical device reported an error.
EFI_NOT_READY	The physical device is busy or not ready to process this request.
EFI_BUFFER_TOO_SMALL	The Supplied buffer is not large enough to hold the message payload.

Related Definitions

```

}  EFI_USBFN_MESSAGE_PAYLOAD;
```

17.3.11 EFI_USBFN_IO_PROTOCOL.Transfer()

Summary

This function handles transferring data to or from the host on the specified endpoint, depending on the direction specified.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_USBFN_IO_TRANSFER) (
  IN EFI_USBFN_IO_PROTOCOL            *This,
  IN UINT8                            EndpointIndex,
  IN EFI_USBFN_ENDPOINT_DIRECTION     Direction,
  IN OUT UINTN                        *BufferSize,
  IN OUT VOID                         *Buffer
  );
```

Parameters

This

A pointer to the *EFI_USBFN_IO_PROTOCOL* instance.

EndpointIndex

Indicates the endpoint on which TX or RX transfer needs to take place.

Direction

Direction of the endpoint. Refer to the **Related Definitions** of the *EFI_USBFN_IO_PROTOCOL.ABORTTRANSFER()* function for details.

BufferSize

If *Direction* is EfiUsbEndpointDirectionDeviceRx: On input, the size of the *Buffer* in bytes. On output, the amount of data returned in *Buffer* in bytes.

If *Direction* is EfiUsbEndpointDirectionDeviceTx: On input, the size of the *Buffer* in bytes. On output, the amount of data transmitted in bytes.

Buffer

If *Direction* is EfiUsbEndpointDirectionDeviceRx: The *Buffer* to return the received data.

If *Direction* is EfiUsbEndpointDirectionDeviceTx: The Buffer that contains the data to be transmitted.

Note: This buffer is allocated and freed using the *EFI_USBFN_IO_PROTOCOL.ABORTTRANSFER()* and *EFI_USBFN_IO_PROTOCOL.FreeTransferBuffer()* functions. The caller of this function must not free or reuse the buffer until *EfiUsbMsgEndpointStatusChangedRx* or *EfiUsbMsgEndpointStatusChangedTx* message was received along with the address of the transfer buffer as part of the message payload. Refer to the function definition for *EFI_USBFN_IO_PROTOCOL.EventHandler()* for more information on various messages and their payloads.

Description

This function handles transferring data to or from the host on the specified endpoint, depending on the direction specified.

Direction	**Description**
EfiUsbEndpointDirectionDeviceTx	Start a transmit transfer on the specified endpoint and return immediately.
EfiUsbEndpointDirectionDeviceRx	Start a receive transfer on the specified endpoint and return immediately with available data.

A class driver must call *EFI_USBFN_IO_PROTOCOL.EventHandler()* repeatedly to receive updates on the transfer status and the number of bytes transferred on various endpoints. Upon an update of the transfer status, the *Buffer* field of the *EFI_USBFN_TRANSFER_RESULT* structure (as described in the function description for *EFI_USBFN_IO_PROTOCOL.EventHandler()* must be initialized with the *Buffer* pointer that was supplied to this method.

The overview of the call sequence is illustrated in Figure *Sequence of Operations with Endpoint Policy Changes*.

This function should fail with *EFI_INVALID_PARAMETER* if the specified direction is incorrect for the endpoint.

Status Codes Returned

EFI_SUCCESS	The function returned successfully.
EFI_INVALID_PARAMETER	A parameter is invalid.
EFI_DEVICE_ERROR	The physical device reported an error.
EFI_NOT_READY	The physical device is busy or not ready to process this request.

17.3.12 EFI_USBFN_IO_PROTOCOL.GetMaxTransferSize()

Summary

Returns the maximum supported transfer size.

Prototype

```
typedef
EFI_STATUS
(EFIAPI * EFI_USBFN_IO_GET_MAXTRANSFER_SIZE) (
  IN EFI_USBFN_IO_PROTOCOL              *This,
  OUT UINTN                             *MaxTransferSize
  );
```

Parameters

This

A pointer to the *EFI_USBFN_IO_PROTOCOL* instance.

MaxTransferSize

The maximum supported transfer size, in bytes.

Description

Returns the maximum number of bytes that the underlying controller can accommodate in a single transfer.

Status Codes Returned

EFI_SUCCESS	The function returned successfully.
EFI_INVALID_PARAMETER	A parameter is invalid.
EFI_DEVICE_ERROR	The physical device reported an error.
EFI_NOT_READY	The physical device is busy or not ready to process this request.

17.3.13 EFI_USBFN_IO_PROTOCOL.AllocateTransferBuffer()

Summary

Allocates a transfer buffer of the specified size that satisfies the controller requirements.

Prototype

```
typedef
EFI_STATUS
(EFIAPI * EFI_USBFN_IO_ALLOCATE_TRANSFER_BUFFER) (
  IN EFI_USBFN_IO_PROTOCOL       *This,
  IN UINTN                       Size,
  OUT VOID                       **Buffer
  );
```

Parameters

This

A pointer to the *EFI_USBFN_IO_PROTOCOL* instance.

Size

The number of bytes to allocate for the transfer buffer.

Buffer

A pointer to a pointer to the allocated buffer if the call succeeds; undefined otherwise.

Description

The *AllocateTransferBuffer()* function allocates a memory region of *Size* bytes and returns the address of the allocated memory that satisfies the underlying controller requirements in the location referenced by *Buffer*.

The allocated transfer buffer must be freed using a matching call *EFI_USBFN_IO_PROTOCOL.FreeTransferBuffer()* function.

Status Codes Returned

EFI_SUCCESS	The function returned successfully.
EFI_INVALID_PARAMETER	A parameter is invalid.
EFI_OUT_OF_RESOURCES	The requested transfer buffer could not be allocated.

17.3.14 EFI_USBFN_IO_PROTOCOL.FreeTransferBuffer()

Summary

Deallocates the memory allocated for the transfer buffer by the *EFI_USBFN_IO_PROTOCOL.AllocateTransferBuffer()* function.

Prototype

```
typedef
EFI_STATUS
(EFIAPI * EFI_USBFN_IO_FREE_TRANSFER_BUFFER) (
  IN EFI_USBFN_IO_PROTOCOL         *This,
  IN VOID                          *Buffer
  );
```

Parameters

This
A pointer to the *EFI_USBFN_IO_PROTOCOL* instance.

Buffer
A pointer to the transfer buffer to deallocate.

Description

The *EFI_USBFN_IO_PROTOCOL.FreeTransferBuffer()* function deallocates the memory specified by *Buffer*. The Buffer that is freed must have been allocated by *EFI_USBFN_IO_PROTOCOL.AllocateTransferBuffer()*.

Status Codes Returned

EFI_SUCCESS	The function returned successfully.
EFI_INVALID_PARAMETER	A parameter is invalid.

17.3.15 EFI_USBFN_IO_PROTOCOL.StartController()

Summary

This function supplies power to the USB controller if needed and initializes the hardware and the internal data structures. The port must not be activated by this function

Prototype

```
typedef
EFI_STATUS
(EFIAPI * EFI_USBFN_IO_START_CONTROLLER) (
  IN EFI_USBFN_IO_PROTOCOL       *This
  );
```

Parameters

This
A pointer to the *EFI_USBFN_IO_PROTOCOL* instance.

Description

This function starts the hardware by supplying power to the USB controller if needed, and initializing the hardware and internal data structures. The port must not be activated by this function.

Status Codes Returned

EFI_SUCCESS	The function returned successfully.
EFI_INVALID_PARAMETER	A parameter is invalid.
EFI_DEVICE_ERROR	The physical device reported an error.

17.3.16 EFI_USBFN_IO_PROTOCOL.StopController()

Summary

This function stops the USB hardware device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI * EFI_USBFN_IO_STOP_CONTROLLER) (
  IN EFI_USBFN_IO_PROTOCOL     *This
  );
```

Parameters

This

A pointer to the *EFI_USBFN_IO_PROTOCOL* instance.

17.3.16.1 Description

This function stops the USB hardware device

Status Codes Returned

EFI_SUCCESS	The function returned successfully.
EFI_INVALID_PARAMETER	A parameter is invalid.
EFI_DEVICE_ERROR	The physical device reported an error.

17.3.17 EFI_USBFN_IO_PROTOCOL.SetEndpointPolicy()

Summary

This function sets the configuration policy for the specified non-control endpoint. Refer to the description for calling restrictions.

Prototype

```
typedef
EFI_STATUS
(EFIAPI * EFI_USBFN_SET_ENDPOINT_POLICY) (
  IN EFI_USBFN_IO_PROTOCOL                *This,
  IN UINT8                                EndpointIndex
  IN EFI_USBFN_ENDPOINT_DIRECTION         Direction,
  IN EFI_USBFN_POLICY_TYPE                PolicyType,
  IN UINTN                                BufferSize,
```

(continues on next page)

(continued from previous page)

```
  IN VOID                                   *Buffer
  );
```

Parameters

This

A pointer to the *EFI_USBFN_IO_PROTOCOL* instance.

EndpointIndex

Indicates the non-control endpoint for which the policy needs to be set.

Direction

Direction of the endpoint. Refer to the **Related Definitions** for the *EFI_USBFN_IO_PROTOCOL.AbortTransfer()* function for details.

PolicyType

Policy type the user is trying to set for the specified non-control endpoint. Refer to **Related Definitions** for this function below for details.

BufferSize

The size of the *Buffer* in bytes.

Buffer

The new value for the policy parameter that *PolicyType* specifies. Refer to **Related Definitions** for this function below for details.

Description

This function sets the configuration policy for the specified non-control endpoint. This function can only be called before *EFI_USBFN_IO_PROTOCOL.StartController()* or after *EFI_USBFN_IO_PROTOCOL.StopController()* has been called.

Status Codes Returned

EFI_SUCCESS	The function returned successfully.
EFI_INVALID_PARAMETER	A parameter is invalid.
EFI_DEVICE_ERROR	The physical device reported an error.
EFI_UNSUPPORTED	Changing this policy value is not supported.

Related Definitions

```
typedef enum _EFI_USBFN_POLICY_TYPE
{
  EfiUsbPolicyUndefined = 0,
  EfiUsbPolicyMaxTransactionSize,
  EfiUsbPolicyZeroLengthTerminationSupport,
  EfiUsbPolicyZeroLengthTermination
} EFI_USBFN_POLICY_TYPE;
```

EfiUsbPolicyUndefined

Invalid policy value that must never be used across driver boundary. If used, the function must not return a success status code.

EfiUsbPolicyMaxTransactionSize

EfiUsbPolicyMaxTransactionSize is only used with *EFI_USBFN_IO_PROTOCOL.GETENDPOINTPOLICY()*. It provides the size of the largest single transaction (delivery of service to an endpoint) supported by a controller. It must be greater than or equal to the maximum transfer size that can be retrieved by calling *EFI_USBFN_IO_PROTOCOL.GETMAXTRANSFERSIZE()*.

	GetEndpointPolicy	**SetEndpointPolicy**
BufferSize	4 bytes, sizeof(UINT32)	Not applicable
Return Status	EFI_STATUS	EFI_UNSUPPORTED

EfiUsbPolicyZeroLengthTerminationSupport

EfiUsbPolicyZeroLengthTerminationSupport is only used with XXX *EFI_USBFN_IO_PROTOCOL.GETENDPOINTPOLICY()* . It is **TRUE** if the USB controller is capable of automatically handling zero length packets when the transfer size is a multiple of USB maximum packet size and **FALSE** if it is not supported by the controller.

	GetEndpointPolicy	**SetEndpointPolicy**
BufferSize	1 byte, sizeof (BOOLEAN)	Not applicable
Return Status	EFI_STATUS	EFI_UNSUPPORTED

EfiUsbPolicyZeroLengthTermination

When used with *EFI_USBFN_IO_PROTOCOL.GETENDPOINTPOLICY()* , a **TRUE** value is returned if the USB controller hardware is configured to automatically handle zero length packets when the transfer size is a multiple of USB maximum packet size; a **FALSE** value is returned if the controller hardware is not configured to do this.

Using *EFI_USBFN_IO_PROTOCOL.SETENDPOINTPOLICY()* to set the EfiUsbPolicyZeroLengthTermination policy is only applicable to USB controller hardware capable of supporting automatic zero length packet termination. When this value is set to **TRUE**, the controller must be configured to handle zero length termination for the specified endpoint. When this value is set to **FALSE**, the controller must be configured to not handle zero length termination for the specified endpoint.

The USB controller's default policy must not enable automatic zero length packet termination, even if the hardware is capable of supporting it.

	GetEndpointPolicy	**SetEndpointPolicy**
BufferSize	1 byte, sizeof (BOOLEAN)	1 byte, sizeof (BOOLEAN)
Return Status	EFI_STATUS	EFI_STATUS

17.3.18 EFI_USBFN_IO_PROTOCOL.GetEndpointPolicy()

Summary

This function retrieves the configuration policy for the specified non-control endpoint. There are no associated calling restrictions for this function.

Prototype

```
typedef
EFI_STATUS
(EFIAPI * EFI_USBFN_GET_ENDPOINT_POLICY) (
  IN EFI_USBFN_IO_PROTOCOL           *This,
  IN UINT8                           EndpointIndex
  IN EFI_USBFN_ENDPOINT_DIRECTION    Direction,
  IN EFI_USBFN_POLICY_TYPE           PolicyType,
  IN OUT UINTN                       *BufferSize,
  IN OUT VOID                        *Buffer
  );
```

Parameters

This
A pointer to the *EFI_USBFN_IO_PROTOCOL* instance.

EndpointIndex
Indicates the non-control endpoint for which the policy needs to be set.

Direction
Direction of the endpoint. Refer to the **Related Definitions** for the *EFI_USBFN_IO_PROTOCOL.Aborttransfer()* function for details.

PolicyType
Policy type the user is trying to retrieve for the specified non-control endpoint. Refer to the **Related Definitions** for the *EFI_USBFN_IO_PROTOCOL.Setendpointpolicy()* function for details.

BufferSize
On input, the size of *Buffer* in bytes. On output, the amount of data returned in *Buffer* in bytes.

Buffer
A pointer to a buffer to return requested endpoint policy value. Refer to the **Related Definitions** for the *EFI_USBFN_IO_PROTOCOL.SetEndpointPolicy()* function for size requirements of various policy types.

Description

This function retrieves the configuration policy for the specified non-control endpoint. This function has no calling restrictions.

Status Codes Returned

EFI_SUCCESS	The function returned successfully.
EFI_INVALID_PARAMETER	A parameter is invalid.
EFI_DEVICE_ERROR	The physical device reported an error.
EFI_UNSUPPORTED	The specified policy value is not supported.
EFI_BUFFER_TOO_SMALL	Supplied buffer is not large enough to hold requested policy value.

CHAPTER

EIGHTEEN

PROTOCOLS — DEBUGGER SUPPORT

This chapter describes a minimal set of protocols and associated data structures necessary to enable the creation of source level debuggers for EFI. It does not fully define a debugger design. Using the services described in this document, it should also be possible to implement a variety of debugger solutions.

18.1 Overview

Efficient UEFI driver and application development requires the availability of source level debugging facilities. Although completely on-target debuggers are clearly possible, UEFI debuggers are generally expected to be remotely hosted. That is to say, the debugger itself will be split between two machines, which are the host and target. A majority of debugger code runs on the host that is typically responsible for disassembly, symbol management, source display, and user interface. Similarly, a smaller piece of code runs on the target that establishes the communication to the host and proxies requests from the host. The on-target code is known as the “debug agent.”

The debug agent design is subdivided further into two parts, which are the processor/platform abstraction and the debugger host specific communication grammar. This specification describes architectural interfaces for the former only. Specific implementations for various debugger host communication grammars can be created that make use of the facilities described in this specification.

The processor/platform abstraction is presented as a pair of protocol interfaces, which are the Debug Support protocol and the Debug Port protocol.

The Debug Support protocol abstracts the processor’s debugging facilities, namely a mechanism to manage the processor’s context via caller-installable exception handlers.

The Debug Port protocol abstracts the device that is used for communication between the host and target. Typically this will be a 16550 serial port, 1394 device, or other device that is nominally a serial stream.

Furthermore, a table driven, quiescent, memory-only mechanism for determining the base address of PE32+ images is provided to enable the debugger host to determine where images are located in memory.

Aside from timing differences that occur because of running code associated with the debug agent and user initiated changes to the machine context, the operation of the on-target debugger component must be transparent to the rest of the system. In addition, no portion of the debug agent that runs in interrupt context may make any calls to EFI services or other protocol interfaces.

The services described in this document do not comprise a complete debugger, rather they provide a minimal abstraction required to implement a wide variety of debugger solutions.

18.2 EFI Debug Support Protocol

This section defines the EFI Debug Support protocol which is used by the debug agent.

18.2.1 EFI Debug Support Protocol Overview

The debug-agent needs to be able to gain control of the machine when certain types of events occur; i.e., breakpoints, processor exceptions, etc. Additionally, the debug agent must also be able to periodically gain control during operation of the machine to check for asynchronous commands from the host. The EFI Debug Support protocol services enable these capabilities.

The EFI Debug Support protocol interfaces produce callback registration mechanisms which are used by the debug agent to register functions that are invoked either periodically or when specific processor exceptions. When they are invoked by the Debug Support driver, these callback functions are passed the current machine context record. The debug agent may modify this context record to change the machine context which is restored to the machine after the callback function returns. The debug agent does not run in the same context as the rest of UEFI and all modifications to the machine context are deferred until after the callback function returns.

It is expected that there will typically be two instances of the EFI Debug Support protocol in the system. One associated with the native processor instruction set (IA-32, x64, ARM, RISC-V, or Itanium processor family), and one for the EFI virtual machine that implements EFI byte code (EBC).

While multiple instances of the EFI Debug Support protocol are expected, there must never be more than one for any given instruction set.

18.2.2 EFI_DEBUG_SUPPORT_PROTOCOL

Summary

This protocol provides the services to allow the debug agent to register callback functions that are called either periodically or when specific processor exceptions occur.

GUID

```
#define EFI_DEBUG_SUPPORT_PROTOCOL_GUID \
  {0x2755590C,0x6F3C,0x42FA,\
  {0x9E,0xA4,0xA3,0xBA,0x54,0x3C,0xDA,0x25}}
```

Protocol Interface Structure

```
typedef struct {
  EFI_INSTRUCTION_SET_ARCHITECTURE        Isa;
  EFI_GET_MAXIMUM_PROCESSOR_INDEX         GetMaximumProcessorIndex;
  EFI_REGISTER_PERIODIC_CALLBACK          RegisterPeriodicCallback;
  EFI_REGISTER_EXCEPTION_CALLBACK         RegisterExceptionCallback;
  EFI_INVALIDATE_INSTRUCTION_CACHE        InvalidateInstructionCache;
} EFI_DEBUG_SUPPORT_PROTOCOL;
```

Parameters

Isa

Declares the processor architecture for this instance of the EFI Debug Support protocol.

GetMaximumProcessorIndex

Returns the maximum processor index value that may be used with

EFI_DEBUG_SUPPORT_PROTOCOL.REGISTERPERIODICCALLBACK() EFI_DEBUG_SUPPORT_PROTOCOL.REGISTER
EFI_DEBUG_SUPPORT_PROTOCOL.GETMAXIMUMPROCESSORINDEX() function description.

RegisterPeriodicCallback

Registers a callback function that will be invoked periodically and asynchronously to the execution of EFI. See the RegisterPeriodicCallback()* function description.

RegisterExceptionCallback

Registers a callback function that will be called each time the specified processor exception occurs. See the RegisterExceptionCallback()* function description.

InvalidateInstructionCache

Invalidate the instruction cache of the processor. This is required by processor architectures where instruction and data caches are not coherent when instructions in the code under debug has been modified by the debug agent. *EFI_DEBUG_SUPPORT_PROTOCOL.INVALIDATEINSTRUCTIONCACHE()* function description.

Related Definitions

Refer to the Microsoft PE/COFF Specification revision 6.2 or later for *IMAGE_FILE_MACHINE* definitions.

Note: At the time of publication of this specification, the latest revision of the PE/COFF specification was 6.2. The definition of *IMAGE_FILE_MACHINE* _EBC is not included in revision 6.2 of the PE/COFF specification. It will be added in a future revision of the PE/COFF specification.

```
//
// Machine type definition
//
typedef enum {
  IsaIa32 = IMAGE_FILE_MACHINE_I386,    // 0x014C
  IsaX64 = IMAGE_FILE_MACHINE_X64,    // 0x8664
  IsaIpf = IMAGE_FILE_MACHINE_IA64,   // 0x0200
  IsaEbc = IMAGE_FILE_MACHINE_EBC,    // 0x0EBC
  IsaArm = IMAGE_FILE_MACHINE_ARMTHUMB_MIXED    // 0x1C2
  IsaAArch64 = IMAGE_FILE_MACHINE_AARCH64  // 0xAA64
  IsaRISCV32 = I\nMAGE_FILE_MACHINE_RISCV32  // 0x5032
  IsaRISCV64 = IMAGE_FILE_MACHINE_RISCV64  // 0x5064
  IsaRISCV128 = IMAGE_FILE_MACHINE_RISCV128  // 0x5128
} EFI_INSTRUCTION_SET_ARCHITECTURE;
```

Description

The EFI Debug Support protocol provides the interfaces required to register debug agent callback functions and to manage the processor's instruction stream as required. Registered callback functions are invoked in interrupt context when the specified event occurs.

The driver that produces the EFI Debug Support protocol is also responsible for saving the machine context prior to invoking a registered callback function and restoring it after the callback function returns prior to returning to the code under debug. If the debug agent has modified the context record, the modified context must be used in the restore operation.

Furthermore, if the debug agent modifies any of the code under debug (to set a software breakpoint for example), it must call the *InvalidateInstructionCache()* function for the region of memory that has been modified.

18.2.3 EFI_DEBUG_SUPPORT_PROTOCOL.GetMaximumProcessorIndex()

Summary

Returns the maximum value that may be used for the *ProcessorIndex* parameter in *EFI_DEBUG_SUPPORT_PROTOCOL.REGISTERPERIODICCALLBACK()* and *EFI_DEBUG_SUPPORT_PROTOCOL.REGISTEREXCEPTIONCALLBACK()* .

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_GET_MAXIMUM_PROCESSOR_INDEX) (
  IN EFI_DEBUG_SUPPORT_PROTOCOL            *This,
  OUT UINTN                                *MaxProcessorIndex
);
```

Parameters

This
A pointer to the *EFI_DEBUG_SUPPORT_PROTOCOL* instance. Type EFI_DEBUG_SUPPORT_PROTOCOL is defined in this section.

MaxProcessorIndex
Pointer to a caller-allocated UINTN in which the maximum supported processor index is returned.

Description

The *GetMaximumProcessorIndex()* function returns the maximum processor index in the output parameter *MaxProcessorIndex*. This value is the largest value that may be used in the *ProcessorIndex* parameter for both *RegisterPeriodicCallback()* and *RegisterExceptionCallback()* . All values between 0 and *MaxProcessorIndex* must be supported by *RegisterPeriodicCallback()* and *RegisterExceptionCallback()*.

It is the responsibility of the caller to insure all parameters are correct. There is no provision for parameter checking by *GetMaximumProcessorIndex()*. The implementation behavior when an invalid parameter is passed is not defined by this specification.

Status Codes Returned

EFI_SUCCESS	The function completed successfully.

18.2.4 EFI_DEBUG_SUPPORT_PROTOCOL.RegisterPeriodicCallback()

Summary

Registers a function to be called back periodically in interrupt context.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_REGISTER_PERIODIC_CALLBACK) (
  IN EFI_DEBUG_SUPPORT_PROTOCOL            *This,
  IN UINTN                                 ProcessorIndex,
  IN EFI_PERIODIC_CALLBACK                 PeriodicCallback
);
```

Parameters

This

A pointer to the *EFI_DEBUG_SUPPORT_PROTOCOL* instance. Type EFI_DEBUG_SUPPORT_PROTOCOL is defined in *EFI_DEBUG_SUPPORT_PROTOCOL* .

ProcessorIndex

Specifies which processor the callback function applies to.

PeriodicCallback

A pointer to a function of type *PERIODIC_CALLBACK* that is the main periodic entry point of the debug agent. It receives as a parameter a pointer to the full context of the interrupted execution thread.

Related Definitions

```

```

Description

The *RegisterPeriodicCallback()* function registers and enables the on-target debug agent's periodic entry point. To unregister and disable calling the debug agent's periodic entry point, call *RegisterPeriodicCallback()* passing a **NULL** *PeriodicCallback* parameter.

The implementation must handle saving and restoring the processor context to/from the system context record around calls to the registered callback function.

If the interrupt is also used by the firmware for the EFI time base or some other use, two rules must be observed. First, the registered callback function must be called before any EFI processing takes place. Second, the Debug Support implementation must perform the necessary steps to pass control to the firmware's corresponding interrupt handler in a transparent manner.

There is no quality of service requirement or specification regarding the frequency of calls to the registered *PeriodicCallback* function. This allows the implementation to mitigate a potential adverse impact to EFI timer based services due to the latency induced by the context save/restore and the associated callback function.

It is the responsibility of the caller to insure all parameters are correct. There is no provision for parameter checking by *RegisterPeriodicCallback()*. The implementation behavior when an invalid parameter is passed is not defined by this specification.

Status Codes Returned

EFI_SUCCESS	The function completed successfully.
EFI_ALREADY_STARTED	Non- *NULL* PeriodicCallback parameter when a callback function was previously registered.
EFI_OUT_OF_RESOURCES	System has insufficient memory resources to register new callback function.

18.2.5 EFI_DEBUG_SUPPORT_PROTOCOL.RegisterExceptionCallback()

Summary

Registers a function to be called when a given processor exception occurs.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *REGISTER_EXCEPTION_CALLBACK) (
   IN EFI_DEBUG_SUPPORT_PROTOCOL    *This,
   IN UINTN                         ProcessorIndex,
   IN EFI_EXCEPTION_CALLBACK        ExceptionCallback,
   IN EFI_EXCEPTION_TYPE            ExceptionType
   );
```

Parameters

This

A pointer to the *EFI_DEBUG_SUPPORT_PROTOCOL* instance. Type EFI_DEBUG_SUPPORT_PROTOCOL is defined in *EFI_DEBUG_SUPPORT_PROTOCOL* .

ProcessorIndex

Specifies which processor the callback function applies to.

ExceptionCallback

A pointer to a function of type EXCEPTION_CALLBACK* that is called when the processor exception specified by *ExceptionType* occurs. Passing *NULL* unregisters any previously registered function associated with *ExceptionType*.

ExceptionType

Specifies which processor exception to hook.

```

Description

The *RegisterExceptionCallback()* function registers and enables an exception callback function for the specified exception. The specified exception must be valid for the instruction set architecture. To unregister the callback function and stop servicing the exception, call *RegisterExceptionCallback()* passing a *NULL ExceptionCallback* parameter.

The implementation must handle saving and restoring the processor context to/from the system context record around calls to the registered callback function. No chaining of exception handlers is allowed.

It is the responsibility of the caller to insure all parameters are correct. There is no provision for parameter checking by *RegisterExceptionCallback()*. The implementation behavior when an invalid parameter is passed is not defined by this specification.

Status Codes Returned

EFI_SUCCESS	The function completed successfully.
EFI_ALREADY_STARTED	Non- *NULL* ExceptionCallback parameter when a callback function was previously registered.
EFI_OUT_OF_RESOURCES	System has insufficient memory resources to register new callback function.

18.2.6 EFI_DEBUG_SUPPORT_PROTOCOL.InvalidateInstructionCache()

Summary

Invalidates processor instruction cache for a memory range. Subsequent execution in this range causes a fresh memory fetch to retrieve code to be executed.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_INVALIDATE_INSTRUCTION_CACHE) (
  IN EFI_DEBUG_SUPPORT_PROTOCOL           *This,
  IN UINTN                                ProcessorIndex,
  IN VOID                                 *Start,
  IN UINT64                               Length
  );
```

Parameters

This

A pointer to the *EFI_DEBUG_SUPPORT_PROTOCOL* instance. Type EFI_DEBUG_SUPPORT_PROTOCOL is defined in *EFI_DEBUG_SUPPORT_PROTOCOL* .

ProcessorIndex

Specifies which processor's instruction cache is to be invalidated.

Start

Specifies the physical base of the memory range to be invalidated.

Length

Specifies the minimum number of bytes in the processor's instruction cache to invalidate.

Description

Typical operation of a debugger may require modifying the code image that is under debug. This can occur for many reasons, but is typically done to insert/remove software break instructions. Some processor architectures do not have coherent instruction and data caches so modifications to the code image require that the instruction cache be explicitly invalidated in that memory region.

The *InvalidateInstructionCache()* function abstracts this operation from the debug agent and provides a general purpose capability to invalidate the processor's instruction cache.

It is the responsibility of the caller to insure all parameters are correct. There is no provision for parameter checking by *EFI_DEBUG_SUPPORT_PROTOCOL.REGISTEREXCEPTIONCALLBACK()* . The implementation behavior when an invalid parameter is passed is not defined by this specification.

Status Codes Returned

EFI_SUCCESS	The function completed successfully.

18.3 EFI Debugport Protocol

This section defines the EFI Debugport protocol. This protocol is used by debug agent to communicate with the remote debug host.

18.3.1 EFI Debugport Overview

Historically, remote debugging has typically been done using a standard UART serial port to connect the host and target. This is obviously not possible in a legacy reduced system that does not have a UART. The Debugport protocol solves this problem by providing an abstraction that can support many different types of debugport hardware. The debug agent should use this abstraction to communicate with the host.

The interface is minimal with only reset, read, write, and poll abstractions. Since these functions are called in interrupt context, none of them may call any EFI services or other protocol interfaces.

Debugport selection and configuration is handled by setting defaults via an environment variable which contains a full device path to the debug port. This environment variable is used during the debugport driver's initialization to configure the debugport correctly. The variable contains a full device path to the debugport, with the last node (prior to the terminal node) being a debugport messaging node. See *Debugport Device Path* for details.

The driver must also produce an instance of the EFI Device Path protocol to indicate what hardware is being used for the debugport. This may be used by the OS to maintain the debugport across a call to *EFI_BOOT_SERVICES.ExitBootServices()* .

18.3.2 EFI_DEBUGPORT_PROTOCOL

Summary

This protocol provides the communication link between the debug agent and the remote host.

GUID

```
#define EFI_DEBUGPORT_PROTOCOL_GUID \
  {0xEBA4E8D2,0x3858,0x41EC,\
    {0xA2,0x81,0x26,0x47,0xBA,0x96,0x60,0xD0}}
```

Protocol Interface Structure

```
typedef struct {
  EFI_DEBUGPORT_RESET        Reset;
  EFI_DEBUGPORT_WRITE        Write;
  EFI_DEBUGPORT_READ         Read;
  EFI_DEBUGPORT_POLL         Poll;
} EFI_DEBUGPORT_PROTOCOL;
```

Parameters

Reset
Resets the debugport hardware.

Write
Send a buffer of characters to the debugport device.

Read
Receive a buffer of characters from the debugport device.

Poll
Determine if there is any data available to be read from the debugport device.

Description

The Debugport protocol is used for byte stream communication with a debugport device. The debugport can be a standard UART Serial port, a USB-based character device, or potentially any character-based I/O device.

The attributes for all UART-style debugport device interfaces are defined in the DEBUGPORT variable (*Debugport Device Path*).

18.3.3 EFI_DEBUGPORT_PROTOCOL.Reset()

Summary

Resets the debugport.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_DEBUGPORT_RESET) (
  IN EFI_DEBUGPORT_PROTOCOL        *This
  );
```

Parameters

This
A pointer to the *EFI_DEBUGPORT_PROTOCOL* instance. Type EFI_DEBUGPORT_PROTOCOL is defined in *EFI_DEBUGPORT_PROTOCOL*.

Description

The *Reset()* function resets the debugport device.

It is the responsibility of the caller to insure all parameters are valid. There is no provision for parameter checking by *Reset()*. The implementation behavior when an invalid parameter is passed is not defined by this specification.

Status Codes Returned

EFI_SUCCESS	The debugport device was reset and is in usable state.
EFI_DEVICE_ERROR	The debugport device could not be reset and is unusable.

18.3.4 EFI_DEBUGPORT_PROTOCOL.Write()

Summary

Writes data to the debugport.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_DEBUGPORT_WRITE) (
  IN EFI_DEBUGPORT_PROTOCOL      *This,
  IN UINT32                      Timeout,
  IN OUT UINTN                   *BufferSize,
```

(continues on next page)

(continued from previous page)

```
  IN VOID                         *Buffer
  );
```

Parameters

This

A pointer to the *EFI_DEBUGPORT_PROTOCOL* instance. Type EFI_DEBUGPORT_PROTOCOL is defined in *EFI_DEBUGPORT_PROTOCOL*.

Timeout

The number of microseconds to wait before timing out a write operation.

BufferSize

On input, the requested number of bytes of data to write. On output, the number of bytes of data actually written.

Buffer

A pointer to a buffer containing the data to write.

Description

The *Write()* function writes the specified number of bytes to a debugport device. If a timeout error occurs while data is being sent to the debugport, transmission of this buffer will terminate, and *EFI_TIMEOUT* will be returned. In all cases the number of bytes actually written to the debugport device is returned in *BufferSize*.

It is the responsibility of the caller to insure all parameters are valid. There is no provision for parameter checking by *Write()*. The implementation behavior when an invalid parameter is passed is not defined by this specification.

Status Codes Returned

EFI_SUCCESS	The data was written.
EFI_DEVICE_ERROR	The device reported an error.
EFI_TIMEOUT	The data write was stopped due to a timeout.

18.3.5 EFI_DEBUGPORT_PROTOCOL.Read()

Summary

Reads data from the debugport.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_DEBUGPORT_READ) (
  IN EFI_DEBUGPORT_PROTOCOL         *This,
  IN UINT32                         Timeout,
  IN OUT UINTN                      *BufferSize,
  OUT VOID                          *Buffer
  );
```

Parameters

This

A pointer to the *EFI_DEBUGPORT_PROTOCOL* instance. Type EFI_DEBUGPORT_PROTOCOL is defined in *EFI_DEBUGPORT_PROTOCOL*.

Timeout
The number of microseconds to wait before timing out a read operation.

BufferSize
A pointer to an integer which, on input contains the requested number of bytes of data to read, and on output contains the actual number of bytes of data read and returned in Buffer.

Buffer
A pointer to a buffer into which the data read will be saved.

Description

The *Read()* function reads a specified number of bytes from a debugport. If a timeout error or an overrun error is detected while data is being read from the debugport, then no more characters will be read, and *EFI_TIMEOUT* will be returned. In all cases the number of bytes actually read is returned in * *BufferSize*.

It is the responsibility of the caller to insure all parameters are valid. There is no provision for parameter checking by *Read()*. The implementation behavior when an invalid parameter is passed is not defined by this specification.

Status Codes Returned

EFI_SUCCESS	The data was read.
EFI_DEVICE_ERROR	The debugport device reported an error.
EFI_TIMEOUT	The operation was stopped due to a timeout or overrun.

18.3.6 EFI_DEBUGPORT_PROTOCOL.Poll()

Summary

Checks to see if any data is available to be read from the debugport device.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_DEBUGPORT_POLL) (
  IN EFI_DEBUGPORT_PROTOCOL         *This
  );
```

Parameters

This
A pointer to the *EFI_DEBUGPORT_PROTOCOL* instance. Type EFI_DEBUGPORT_PROTOCOL is defined in *EFI_DEBUGPORT_PROTOCOL*.

Description

The *Poll()* function checks if there is any data available to be read from the debugport device and returns the result. No data is actually removed from the input stream. This function enables simpler debugger design since buffering of reads is not necessary by the caller.

Status Codes Returned

EFI_SUCCESS	At least one byte of data is available to be read.
EFI_NOT_READY	No data is available to be read.
EFI_DEVICE_ERROR	The debugport device is not functioning correctly.

18.3.7 Debugport Device Path

The debugport driver must establish and maintain an instance of the EFI Device Path protocol for the debugport. A graceful handoff of debugport ownership between the EFI Debugport driver and an OS debugport driver requires that the OS debugport driver can determine the type, location, and configuration of the debugport device.

The Debugport Device Path is a vendor-defined messaging device path with no data, only a GUID. It is used at the end of a conventional device path to tag the device for use as the debugport. For example, a typical UART debugport would have the following fully qualified device path:

```
PciRoot(0)/Pci(0x1f,0)/ACPI(PNP0501,0)/UART(115200,N,8,1)/DebugPort()
```

The Vendor_GUID that defines the debugport device path is the same as the debugport protocol GUID, as defined below.

```
#define DEVICE_PATH_MESSAGING_DEBUGPORT \
   EFI_DEBUGPORT_PROTOCOL_GUID
```

The Table below, *Debugport Messaging Device Path*, shows all fields of the debugport device path.

Table 18.1: Debugport Messaging Device Path

Mnemonic	Byte Offset	Byte Length	Description
Type	0	1	Type 3 - Messaging Device Path.
Sub Type	1	1	Sub Type 10 - Vendor.
Length	2	2	Length of this structure in bytes. Length is 20 bytes.
Vendor_GUID	4	16	DEVICE_PATH_MESSA GING_DEBUGPORT.

18.3.8 EFI Debugport Variable

Even though there may be more than one hardware device that could function as a debugport in a system, only one debugport may be active at a time. The DEBUGPORT variable is used to declare which hardware device will act as the debugport, and what communication parameters it should assume.

Like all EFI variables, the DEBUGPORT variable has both a name and a GUID. The name is “DEBUGPORT.” The GUID is the same as the *EFI_DEBUGPORT_PROTOCOL_GUID* :

```
#define EFI_DEBUGPORT_VARIABLE_NAME L"DEBUGPORT"
#define EFI_DEBUGPORT_VARIABLE_GUID EFI_DEBUGPORT_PROTOCOL_GUID
```

The data contained by the DEBUGPORT variable is a fully qualified debugport device path (*Debugport Device Path*).

The desired communication parameters for the debugport are declared in the DEBUGPORT variable. The debugport driver must read this variable during initialization to determine how to configure the debug port.

To reduce the required complexity of the debugport driver, the debugport driver is not required to support all possible combinations of communication parameters. What combinations of parameters are possible is implementation specific.

Additionally debugport drivers implemented for PNP0501 devices, that is debugport devices with a PNP0501 ACPI node in the device path, must support the following defaults. These defaults must be used in the absence of a DEBUGPORT variable, or when the communication parameters specified in the DEBUGPORT variable are not supported by the driver.

- Baud : 115200

- 8 data bits
- No parity
- 1 stop bit
- No flow control (See Appendix A for flow control details)

In the absence of the DEBUGPORT variable, the selection of which port to use as the debug port is implementation specific.

Future revisions of this specification may define new defaults for other debugport types.

The debugport device path must be constructed to reflect the actual settings for the debugport. Any code needing to know the state of the debug port must reference the device path rather than the DEBUGPORT variable, since the debugport may have assumed a default setting in spite of the existence of the DEBUGPORT variable.

If it is not possible to configure the debug port using either the settings declared in the DEBUGPORT variable or the default settings for the particular debugport type, the driver initialization must not install any protocol interfaces and must exit with an error.

18.4 EFI Debug Support Table

This chapter defines the EFI Debug Support Table which is used by the debug agent or an external debugger to determine loaded image information in a quiescent manner.

18.4.1 Overview

Every executable image loaded in EFI is represented by an EFI handle populated with an instance of the *EFI Loaded Image Protocol* protocol. This handle is known as an “image handle.” The associated Loaded Image protocol provides image information that is of interest to a source level debugger. Normal EFI executables can access this information by using EFI services to locate all instances of the Loaded Image protocol.

A debugger has two problems with this scenario. First, if it is an external hardware debugger, the location of the EFI system table is not known. Second, even if the location of the EFI system table is known, the services contained therein are generally unavailable to a debugger either because it is an on-target debugger that is running in interrupt context, or in the case of an external hardware debugger there is no debugger code running on the target at all.

Since a source level debugger must be capable of determining image information for all loaded images, an alternate mechanism that does not use EFI services must be provided. Two features are added to the EFI system software to enable this capability.

First, an alternate mechanism of locating the EFI system table is required. A check-summed structure containing the physical address of the EFI system table is created and located on a 4M aligned memory address. A hardware debugger can search memory for this structure to determine the location of the EFI system table.

Second, an *EFI_CONFIGURATION_TABLE* is published that leads to a database of pointers to all instances of the Loaded Image protocol. Several layers of indirection are used to allow dynamically managing the data as images are loaded and unloaded. Once the address of the EFI system table is known, it is possible to discover a complete and accurate list of EFI images. (Note that the EFI core itself must be represented by an instance of the Loaded Image protocol.)

Debug Support Table Indirection and Pointer Usage illustrates the table indirection and pointer usage.

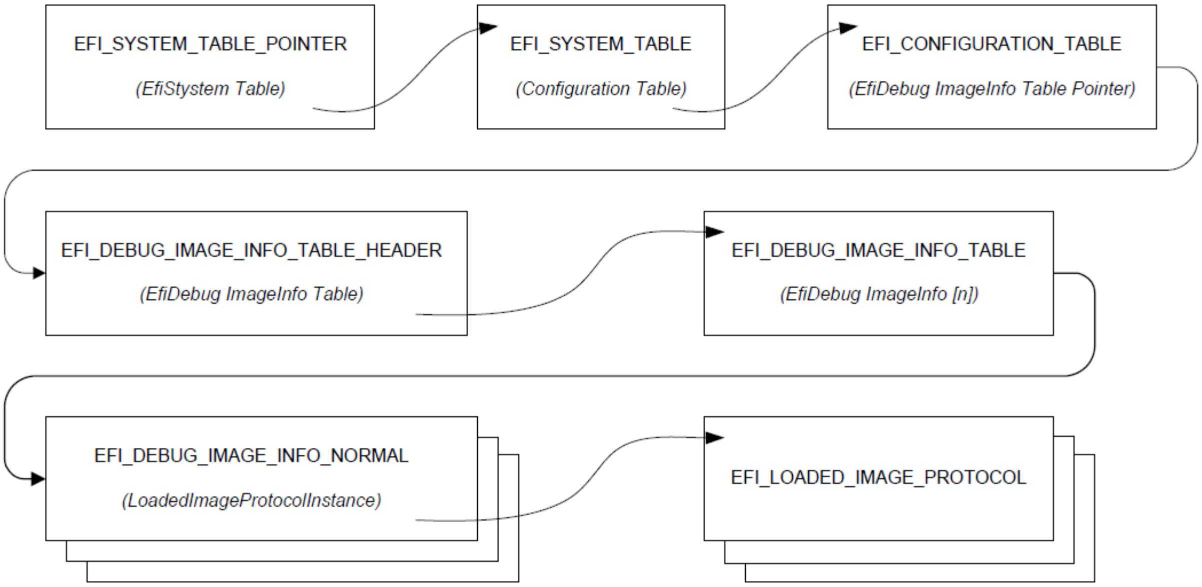

Fig. 18.1: Debug Support Table Indirection and Pointer Usage

18.4.2 EFI System Table Location

The EFI system table can be located by an off-target hardware debugger by searching for the *EFI_SYSTEM_TABLE_POINTER* structure. The *EFI_SYSTEM_TABLE_POINTER* structure is located on a 4M boundary as close to the top of physical memory as feasible. It may be found searching for *the EFI_SYSTEM_TABLE_SIGNATURE* on each 4M boundary starting at the top of memory and scanning down. When the signature is found, the entire structure must verified using the *Crc32* field. The 32-bit CRC of the entire structure is calculated assuming the *Crc32* field is zero. This value is then written to the *Crc32* field.

```
typedef struct _EFI_SYSTEM_TABLE_POINTER {
   UINT64                      Signature;
   EFI_PHYSICAL_ADDRESS        EfiSystemTableBase;
   UINT32                      Crc32;
   } EFI_SYSTEM_TABLE_POINTER;
```

Signature
A constant UINT64 that has the value EFI_SYSTEM_TABLE_SIGNATURE (see the EFI 1.0 specification).

EfiSystemTableBase
The physical address of the EFI system table.

Crc32
A 32-bit CRC value that is used to verify the *EFI_SYSTEM_TABLE_POINTER* structure is valid.

18.4.3 EFI Image Info

The *EFI_DEBUG_IMAGE_INFO_TABLE* is an array of pointers to *EFI_DEBUG_IMAGE_INFO* unions. Each member of an *EFI_DEBUG_IMAGE_INFO* union is a pointer to a data structure representing a particular image type. For each image that has been loaded, there is an appropriate image data structure with a pointer to it stored in the *EFI_DEBUG_IMAGE_INFO_TABLE*. Data structures for normal images and SMM images are defined. All other image types are reserved for future use.

The process of locating the *EFI_DEBUG_IMAGE_INFO_TABLE* begins with an EFI configuration table.

```
//
// EFI_DEBUG_IMAGE_INFO_TABLE configuration table
//     GUID declaration - {49152E77-1ADA-4764-B7A2-7AFEFED95E8B}
//
#define EFI_DEBUG_IMAGE_INFO_TABLE_GUID \
  {0x49152E77,0x1ADA,0x4764,\
    {0xB7,0xA2,0x7A,0xFE,0xFE,0xD9,0x5E,0x8B }}
```

The address reported in the EFI configuration table entry of this type will be referenced as physical and will not be fixed up when transition from preboot to runtime phase.

The configuration table leads to an *EFI_DEBUG_IMAGE_INFO_TABLE_HEADER* structure that contains a pointer to the *EFI_DEBUG_IMAGE_INFO_TABLE* and some status bits that are used to control access to the *EFI_DEBUG_IMAGE_INFO_TABLE* when it is being updated.

```
//
// UpdateStatus bits
//
#define EFI_DEBUG_IMAGE_INFO_UPDATE_IN_PROGRESS    0x01
#define EFI_DEBUG_IMAGE_INFO_TABLE_MODIFIED        0x02

typedef struct {
   volatile UINT32              UpdateStatus;
   UINT32                       TableSize;
   EFI_DEBUG_IMAGE_INFO         *EfiDebugImageInfoTable;
} EFI_DEBUG_IMAGE_INFO_TABLE_HEADER;
```

UpdateStatus

UpdateStatus is used by the system to indicate the state of the debug image info table.

The EFI_DEBUG_IMAGE_INFO_UPDATE_IN_PROGRESS bit must be set when the table is being modified. Software consuming the table must qualify the access to the table with this bit.

The EFI_DEBUG_IMAGE_INFO_TABLE_MODIFIED bit is always set by software that modifies the table. It may be cleared by software that consumes the table once the entire table has been read. It is essentially a sticky version of the EFI_DEBUG_IMAGE_INFO_UPDATE_IN_PROGRESS bit and is intended to provide an efficient mechanism to minimize the number of times the table must be scanned by the consumer.

TableSize

The number of EFI_DEBUG_IMAGE_INFO elements in the array pointed to by *EfiDebugImageInfoTable*.

EfiDebugImageInfoTable

A pointer to the first element of an array of EFI_DEBUG_IMAGE_INFO structures.

```
#define EFI_DEBUG_IMAGE_INFO_TYPE_NORMAL 0x01

typedef union {
```

(continues on next page)

(continued from previous page)

```
  UINT32                        *ImageInfoType;
  EFI_DEBUG_IMAGE_INFO_NORMAL   *NormalImage;
} EFI_DEBUG_IMAGE_INFO;

typedef struct {
  UINT32                        ImageInfoType;
  EFI_LOADED_IMAGE_PROTOCOL     *LoadedImageProtocolInstance;
  EFI_HANDLE                    ImageHandle;
} EFI_DEBUG_IMAGE_INFO_NORMAL;
```

ImageInfoType

Indicates the type of image info structure. For PE32 EFI images, this is set to EFI_DEBUG_IMAGE_INFO_TYPE_NORMAL.

LoadedImageProtocolInstance

A pointer to an instance of the loaded image protocol for the associated image.

ImageHandle

Indicates the image handle of the associated image.

CHAPTER

NINETEEN

PROTOCOLS — COMPRESSION ALGORITHM SPECIFICATION

In EFI firmware storage, binary codes/data are often compressed to save storage space. These compressed codes/data are extracted into memory for execution at boot time. This demands an efficient lossless compression/decompression algorithm. The compressor must produce small compressed images, and the decompressor must operate fast enough to avoid delays at boot time.

This chapter describes in detail the UEFI compression/decompression algorithm, as well as the EFI Decompress Protocol. The EFI Decompress Protocol provides a standard decompression interface for use at boot time.

19.1 Algorithm Overview

In this chapter, the term "character" denotes a single byte and the term "string" denotes a series of concatenated characters.

The compression/decompression algorithm used in EFI firmware storage is a combination of the LZ77 algorithm and Huffman Coding. The LZ77 algorithm replaces a repeated string with a pointer to the previous occurrence of the string. Huffman Coding encodes symbols in a way that the more frequently a symbol appears in a text, the shorter the code that is assigned to it.

The compression process contains two steps:

- The first step is to find repeated strings (using LZ77 algorithm) and produce intermediate data.

  Beginning with the first character, the compressor scans the source data and determines if the characters starting at the current position can form a string previously appearing in the text. If a long enough matching string is found, the compressor will output a pointer to the string. If the pointer occupies more space than the string itself, the compressor will output the original character at the current position in the source data. Then the compressor advances to the next position and repeats the process. To speed up the compression process, the compressor dynamically maintains a **String Info Log** to record the positions and lengths of strings encountered, so that string comparisons are performed quickly by looking up the String Info Log.

  Because a compressor cannot have unlimited resources, as the compression continues the compressor removes "old" string information. This prevents the String Info Log from becoming too large. As a result, the algorithm can only look up repeated strings within the range of a fixed-sized "sliding window" behind the current position.

  In this way, a stream of intermediate data is produced which contains two types of symbols: the **Original Characters** (to be preserved in the decompressed data), and the **Pointers** (representing a previous string). A Pointer consists of two elements: the **String Position** and the **String Length**, representing the location and the length of the target string, respectively.

- To improve the compression ratio further, Huffman Coding is utilized as the second step.

  The intermediate data (consisting of original characters and pointers) is divided into Blocks so that the compressor can perform Huffman Coding on a Block immediately after it is generated; eliminating the need for a second pass from the beginning after the intermediate data has been generated. Also, since symbol frequency distribution may differ in different parts of the intermediate data, Huffman Coding can be optimized for each specific Block. The compressor determines Block Size for each Block according to the specifications defined in *Data Format* .

In each Block, two symbol sets are defined for Huffman Coding. The Char&Len Set consists of the Original Characters plus the String Lengths and the Position Set consists of String Positions (Note that the two elements of a Pointer belong to separate symbol sets). The Huffman Coding schemes applied on these two symbol sets are independent.

The algorithm uses "canonical" Huffman Coding so a Huffman tree can be represented as an array of code lengths in the order of the symbols in the symbol set. This code length array represents the Huffman Coding scheme for the symbol set. Both the Char&Len Set code length array and the Position Set code length array appear in the Block Header.

Huffman coding is used on the code length array of the Char&Len Set to define a third symbol set. The Extra Set is defined based on the code length values in the Char&Len Set code length array. The code length array for the Huffman Coding of Extra Set also appears in the Block Header together with the other two code length arrays. For exact format of the Block Header, *Block Header*.

The decompression process is straightforward given that the compression process is known. The decompressor scans the compressed data and decodes the symbols one by one, according to the Huffman code mapping tables generated from code length arrays. Along the process, if it encounters an original character, it outputs it; if it encounters a pointer, it looks it up in the already decompressed data and outputs the associated string.

19.2 Data Format

This section describes in detail the format of the compressed data produced by the compressor. The compressed data serves as input to the decompressor and can be fully extracted to the original source data.

19.2.1 Bit Order

In computer data representation, a byte is the minimum unit and there is no differentiation in the order of bits within a byte. However, the compressed data is a sequence of bits rather than a sequence of bytes and as a result the order of bits in a byte needs to be defined. In a compressed data stream, the higher bits are defined to precede the lower bits in a byte. The Figure, below, *Bit Sequence of Compressed Data* illustrates a compressed data sequence written as bytes from left to right. For each byte, the bits are written in an order with bit 7 (the highest bit) at the left and bit 0 (the lowest bit) at the right. Concatenating the bytes from left to right forms a bit sequence.

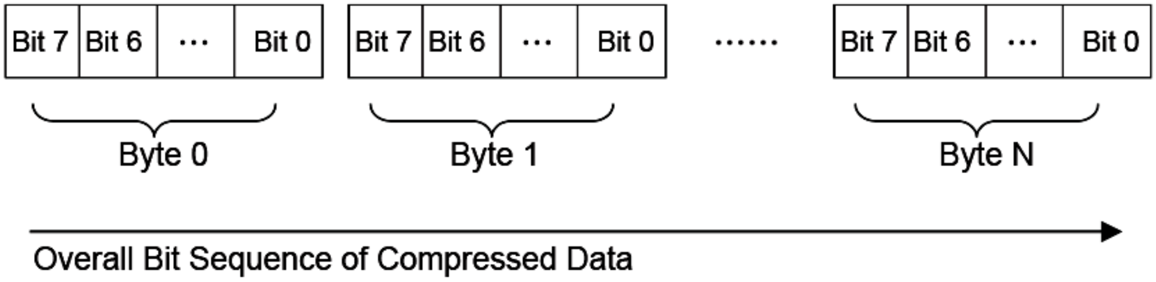

Fig. 19.1: Bit Sequence of Compressed Data

The bits of the compressed data are actually formed by a sequence of data units. These data units have variable bit lengths. The bits of each data unit are arranged so that the higher bit of the data unit precedes the lower bit of the data unit.

19.2.2 Overall Structure

The compressed data begins with two 32-bit numerical fields: the compressed size and the original size. The compressed data following these two fields is composed of one or more Blocks. Each Block is a unit for Huffman Coding with a coding scheme independent of the other Blocks. Each Block is composed of a Block Header containing the Huffman code trees for this Block and a Block Body with the data encoded using the coding scheme defined by the Huffman trees. The compressed data is terminated by an additional byte of zero.

The overall structure of the compressed data is shown in *Compressed Data Structure* .

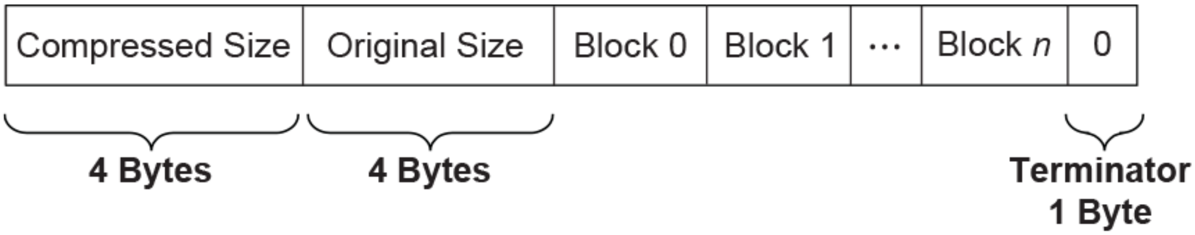

Fig. 19.2: **Compressed Data Structure**

Note the following:

- Blocks are of variable lengths.
- Block lengths are counted by bits and not necessarily divisible by 8. Blocks are tightly packed (there are no padding bits between blocks). Neither the starting position nor ending position of a Block is necessarily at a byte boundary. However, if the last Block is not terminated at a byte boundary, there should be some bits of 0 to fill up the remaining bits of the last byte of the block, before the terminator byte of 0.
- Compressed Size =

  Size in bytes of (Block 0 + Block 1 +… + Block N + Filling Bits (if any) + Terminator).
- Original Size is the size in bytes of original data.
- Both Compressed Size and Original Size are “little endian” (starting from the least significant byte).

19.2.3 Block Structure

A Block is composed of a Block Header and a Block Body, as shown in the figure below. These two parts are packed tightly (there are no padding bits between them). The lengths in bits of Block Header and Block Body are not necessarily divisible by eight.

Fig. 19.3: **Block Structure**

19.2.3.1 Block Header

The Block Header contains the Huffman encoding information for this block. Since "canonical" Huffman Coding is being used, a Huffman tree is represented as an array of code lengths in increasing order of the symbols in the symbol set. Code lengths are limited to be less than or equal to 16 bits. This requires some extra handling of Huffman codes in the compressor, which is described in *Block Structure* .

There are three code length arrays for three different symbol sets in the Block Header: one for the Extra Set, one for the Char&Len Set, and one for the Position Set.

The Block Header is composed of the tightly packed (no padding bits) fields described in the Table, below, *Block Header Fields* .

Table 19.1: Block Header Fields

Field Name	**Length (bits)**	**Description**
Block Size	16	The size of this Block. Block Size is defined as the number of original characters plus the number of pointers that appear in the Block Body: Block Size = Number of Original Characters in the Block Body + Number of Pointers in the Block Body.
Extra Set Code Length Array Size	5	The number of code lengths in the Extra Set Code Length Array. The Extra Set Code Length Array contains code lengths of the Extra Set in increasing order of the symbols, and if all symbols greater than a certain symbol have zero code length, the Extra Set Code Length Array terminates at the last nonzero code length symbol. Since there are 19 symbols in the Extra Set (see the description of the Char&Len Set Code Length Array), the maximum Extra Set Code Length Array Size is 19.

continues on next page

Table 19.1 – continued from previous page

Extra Set Code Length Array	Variable	If Extra Set Code Length Array Size is 0, then this field is a 5-bit value that represents the only Huffman code used. If Extra Set Code Length Array Size is not 0, then this field is an encoded form of a concatenation of code lengths in increasing order of the symbols. The concatenation of Code lengths are encoded as follows: If a code length is less than 7, then it is encoded as a 3-bit value; If a code length is equal to or greater than 7, then it is encoded as a series of "1"s followed by a terminating "0." The number of "1"s = Code length - 4. For example, code length "ten" is encoded as "1111110"; code length "seven" is encoded as "1110." After the third length of the code length concatenation, a 2-bit value is used to indicate the number of consecutive zero lengths immediately after the third length. (Note this 2-bit value only appears once after the third length, and does NOT appear multiple times after every 3rd length.) This 2-bit value ranges from 0 to 3. For example, if the 2-bit value is "00," then it means there are no zero lengths at the point, and following encoding starts from the fourth code length; if the 2-bit value is "10" then it means the fourth and fifth length are zero and following encoding starts from the sixth code length.
Position Set Code Length Array Size	4	The number of code lengths in the Position Set Code Length Array. The Position Set Code Length Array contains code lengths of Position Set in increasing order of the symbols in the Position Set, and if all symbols greater than a certain symbol have zero code length, the Position Set Code Length Array terminates at the last nonzero code length symbol. Since there are 14 symbols in the Position Set (see 3.3.2), the maximum Position Set Code Length Array Size is 14.

continues on next page

Table 19.1 – continued from previous page

Char&Len Set Code Length Array	Variable	If Char&Len Set Code Length Array Size is 0, then this field is a 9-bit value that represents the only Huffman code used. If Char&Len Set Code Length Array Size is not 0, then this field is an encoded form of a concatenation of code lengths in increasing order of the symbols. The concatenation of Code lengths are two-step encoded: Step 1: If a code length is not zero, then it is encoded as "code length + 2"; If a code length is zero, then the number of consecutive zero lengths starting from this code length is counted — • If the count is equal to or less than 2, then the code "0" is used for each zero length; • if the count is greater than 2 and less than 19, then the code "1" followed by a 4-bit value of "count - 3" is used for these consecutive zero lengths; • if the count is equal to 19, then it is treated as "1 + 18," and a code "0" and a code "1" followed by a 4-bit value of "15" are used for these consecutive zero lengths; • if the count is greater than 19, then the code "2" followed by a 9-bit value of "count - 20" is used for these consecutive zero lengths. Step 2: The second step encoding is a Huffman encoding of the codes produced by first step. (While encoding codes "1" and "2," their appended values are not encoded and preserved in the resulting text). The code lengths of generated Huffman tree are just the contents of the Extra Set Code Length Array.
Position Set Code Length Array Size	4	The number of code lengths in the Position Set Code Length Array. The Position Set Code Length Array contains code lengths of Position Set in increasing order of the symbols in the Position Set, and if all symbols greater than a certain symbol have zero code length, the Position Set Code Length Array terminates at the last nonzero code length symbol. Since there are 14 symbols in the Position Set (see 3.3.2), the maximum Position Set Code Length Array Size is 14.

continues on next page

Table 19.1 – continued from previous page

Position Set Code Length Array	Variable	If Position Set Code Length Array Size is 0, then this field is a 5-bit value that represents the only Huffman code used. If Position Set Code Length Array Size is not 0, then this field is an encoded form of a concatenation of code lengths in increasing order of the symbols. The concatenation of Code lengths are encoded as follows: If a code length is less than 7, then it is encoded as a normal 3-bit value; If a code length is equal to or greater than 7, then it is encoded as a series of "1"s followed by a terminating "0." The number of "1"s = Code length - 4. For example, code length "10" is encoded as "1111110"; code length "7" is encoded as "1110."

19.2.3.2 Block Body

The Block Body is simply a mixture of Original Characters and Pointers, while each Pointer has two elements: String Length preceding String Position. All these data units are tightly packed together.

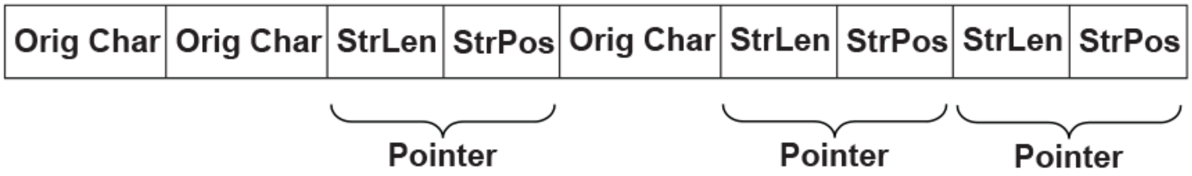

Fig. 19.4: **Block Body**

The Original Characters, String Lengths and String Positions are all Huffman coded using the Huffman trees presented in the Block Header, with some additional variations. The exact format is described below:

An Original Character is a byte in the source data. A String Length is a value that is greater than 3 and less than 257 (this range should be ensured by the compressor). By calculating "(String Length - 3) | 0x100," a value set is obtained that ranges from 256 to 509. By combining this value set with the value set of Original Characters (0 ~ 255), the Char&Len Set (ranging from 0 to 509) is generated for Huffman Coding.

A String Position is a value that indicates the distance between the current position and the target string. The String Position value is defined as "Current Position - Starting Position of the target string - 1." The String Position value ranges from 0 to 8190 (so 8192 is the "sliding window" size, and this range should be ensured by the compressor). The lengths of the String Position values (in binary form) form a value set ranging from 0 to 13 (it is assumed that value 0 has length of 0). This value set is the Position Set for Huffman Coding. The full representation of a String Position value is composed of two consecutive parts: one is the Huffman code for the value length; the other is the actual String Position value of "length - 1" bits (excluding the highest bit since the highest bit is always "1"). For example, String Position value 18 is represented as: Huffman code for "5" followed by "0010." If the value length is 0 or 1, then no value is appended to the Huffman code. This kind of representation favors small String Position values, which is a hint for compressor design.

19.3 Compressor Design

The compressor takes the source data as input and produces a compressed image. This section describes the design used in one possible implementation of a compressor that follows the UEFI Compression Algorithm. The source code that illustrates an implementation of this specific design is listed in Appendix H.

19.3.1 Overall Process

The compressor scans the source data from the beginning, character by character. As the scanning proceeds, the compressor generates Original Characters or Pointers and outputs the compressed data packed in a series of Blocks representing individual Huffman coding units.

The compressor maintains a String Info Log containing data that facilitates string comparison. Old data items are deleted and new data items are inserted regularly.

The compressor does not output a Pointer immediately after it sees a matching string for the current position. Instead, it delays its decision until it gets the matching string for the next position. The compressor has two criteria at hand: one is that the former match length should be no shorter than three characters; the other is that the former match length should be no shorter than the latter match length.

Only when these two criteria are met does the compressor output a Pointer to the former matching string.

The overall process of compression can be described by following pseudo code:

```
Set the Current Position at the beginning of the source data;
Delete the outdated string info from the String Info Log;
Search the String Info Log for matching string;
Add the string info of the current position into the String Info Log;
WHILE not end of source data DO
  Remember the last match;
  Advance the Current Position by 1;
  Delete the outdated String Info from the String Info Log;
  Search the String Info Log for matching string;
  Add the string info of the Current Position into the String Info Log;
  IF the last match is shorter than 3 characters or this match is longer than
   the last match THEN
    Call Output()* to output the character at the previous position as an
    Original Character;
ELSE
  Call Output()* to output a Pointer to the last matching string;
  WHILE (--last match length) > 0 DO
    Advance the Current Position by 1;
    Delete the outdated piece of string info from the String Info Log;
    Add the string info of the current position into the String Info Log;
   ENDWHILE
 ENDIF
ENDWHILE
```

The Output() is the function that is responsible for generating Huffman codes and Blocks. It accepts an Original Character or a Pointer as input and maintains a Block Buffer to temporarily store data units that are to be Huffman coded. The following pseudo code describes the function:

```
FUNCTION NAME: Output
INPUT: an Original Character or a Pointer
```

(continues on next page)

(continued from previous page)

```
Put the Original Character or the Pointer into the Block Buffer;
Advance the Block Buffer position pointer by 1;
IF the Block Buffer is full THEN
  Encode the Char&Len Set in the Block buffer;
  Encode the Position Set in the Block buffer;
  Encode the Extra Set;
  Output the Block Header containing the code length arrays;
  Output the Block Body containing the Huffman encoded Original Characters and
  Pointers;
  Reset the Block Buffer position pointer to point to the beginning of the Block buffer;
ENDIF
```

19.3.2 String Info Log

The provision of the String Info Log is to speed up the process of finding matching strings. The design of this has significant impact on the overall performance of the compressor. This section describes in detail how String Info Log is implemented and the typical operations on it.

19.3.2.1 Data Structures

The String Info Log is implemented as a set of search trees. These search trees are dynamically updated as the compression proceeds through the source data. The structure of a typical search tree is depicted in the Figure, below, *String Info Log Search Tree* .

There are three types of nodes in a search tree: the root node, internal nodes, and leaves. The root node has a “character” attribute, which represents the starting character of a string. Each edge also has a “character” attribute, which represents the next character in the string. Each internal node has a “level” attribute, which indicates the character on any edge that leads to its child nodes is the “level + 1”th character in the string. Each internal node or leaf has a “position” attribute that indicates the string’s starting position in the source data.

To speed up the tree searching, a hash function is used. Given the parent node and the edge-character, the hash function will quickly find the expected child node.

19.3.2.2 Searching the Tree

Traversing the search tree is performed as follows:

The following example uses the search tree shown in the Figure, above, *String Info Log Search Tree* . Assume that the current position in the source data contains the string “camxrsxpj. . . .”

1. The starting character “c” is used to find the root of the tree. The next character “a” is used to follow the edge from node 1 to node 2. The “position” of node 2 is 500, so a string starting with “ca” can be found at position 500. The string at the current position is compared with the string starting at position 500.
2. Node 2 is at Level 3; so at most three characters are compared. Assume that the three-character comparison passes.
3. The fourth character “x” is used to follow the edge from Node 2 to Node 5. The position value of node 5 is 400, which means there is a string located in position 400 that starts with “cam” and the character at position 403 is an “x.”

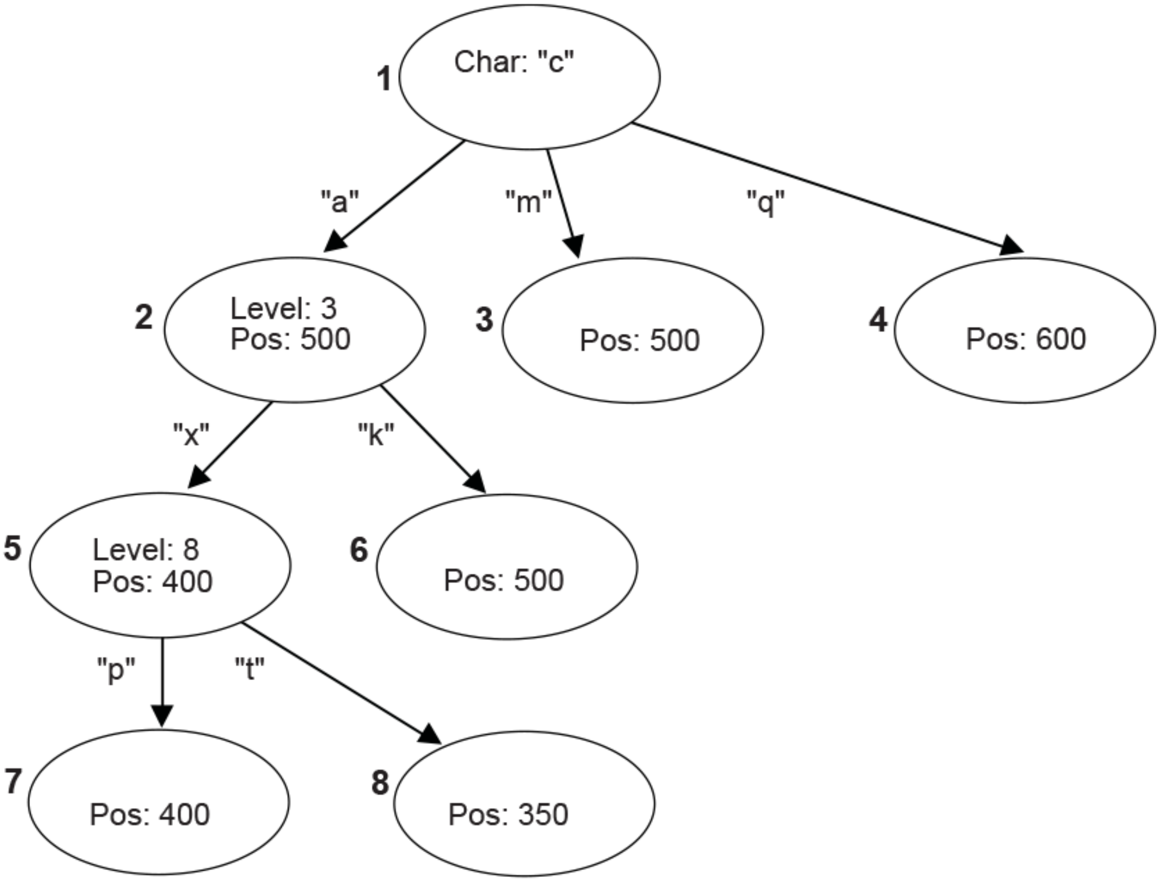

Fig. 19.5: String Info Log Search Tree

4. Node 5 is at Level 8, so the fifth to eighth characters of the source data are compared with the string starting at position 404. Assume the strings match.
5. At this point, the ninth character "p" has been reached. It is used to follow the edge from Node 5 to Node 7.
6. This process continues until a mismatch occurs, or the length of the matching strings exceeds the predefined MAX_MATCH_LENGTH. The most recent matching string (which is also the longest) is the desired matching string.

19.3.2.3 Adding String Info

String info needs to be added to the String Info Log for each position in the source data. Each time a search for a matching string is performed, the new string info is inserted for the current position. There are several cases that can be discussed:

1. No root is found for the first character. A new tree is created with the root node labeled with the starting character and a child leaf node with its edge to the root node labeled with the second character in the string. The "position" value of the child node is set to the current position.
2. One root node matches the first character, but the second character does not match any edge extending from the root node. A new child leaf node is created with its edge labeled with the second character. The "position" value of the new leaf child node is set to the current position.
3. A string comparison succeeds with an internal node, but a matching edge for the next character does not exist. This is similar to (2) above. A new child leaf node is created with its edge labeled with the character that does not exist. The "position" value of the new leaf child node is set to the current position.
4. A string comparison exceeds MAX_MATCH_LENGTH. Note: This only happens with leaf nodes. For this case, the "position" value in the leaf node is updated with the current position.
5. If a string comparison with an internal node or leaf node fails (mismatch occurs before the "Level + 1"th character is reached or MAX_MATCH_LENGTH is exceeded), then a "split" operation is performed as follows:

   Suppose a comparison is being performed with a level 9 Node, at position 350, and the current position is 1005. If the sixth character at position 350 is an "x" and the sixth character at position 1005 is a "y," then a mismatch will occur. In this case, a new internal node and a new child node are inserted into the tree, as depicted in *Node Split* .

19.3.2.4 Deleting String Info

The String Info Log will grow as more and more string information is logged. The size of the String Info Log must be limited, so outdated information must be removed on a regular basis. A sliding window is maintained behind the current position, and the searches are always limited within the range of the sliding window. Each time the current position is advanced, outdated string information that falls outside the sliding window should be removed from the tree. The search for outdated string information is simplified by always updating the nodes' "position" attribute when searching for matching strings.

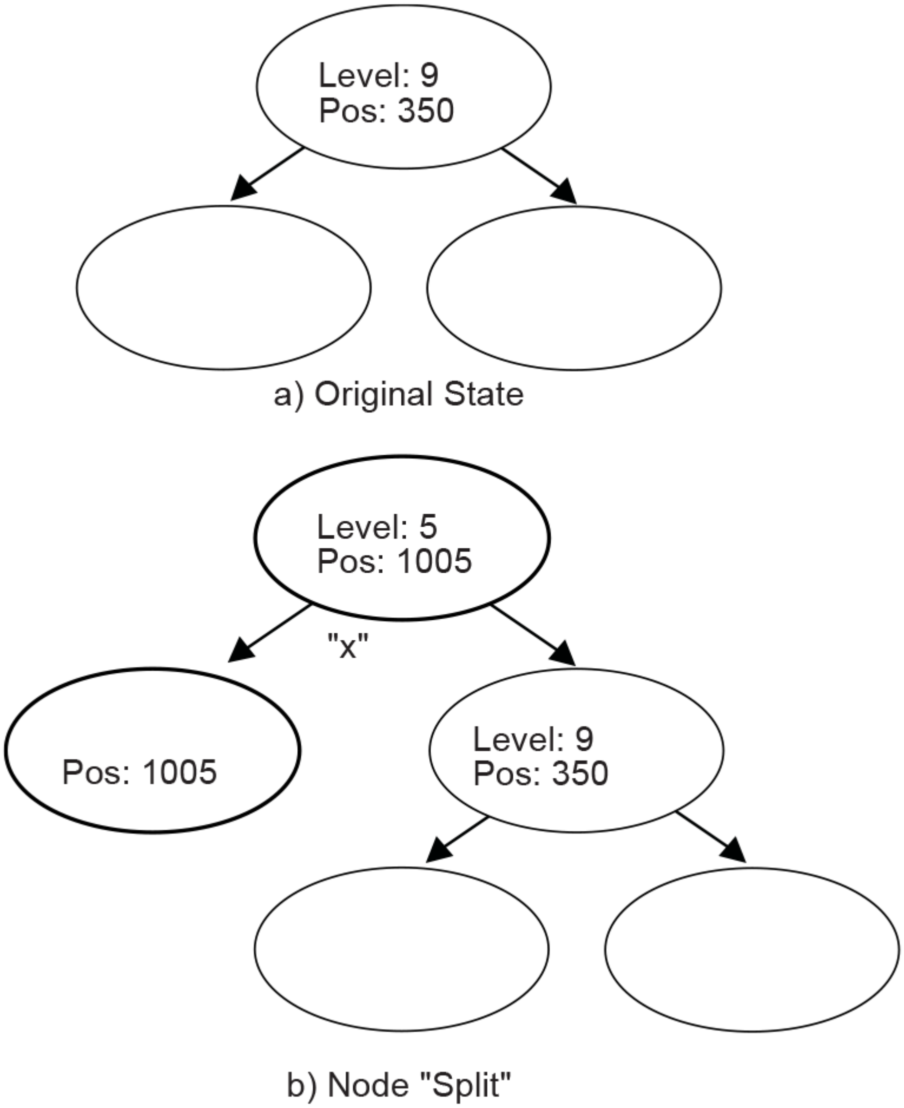

Fig. 19.6: Node Split

The b) portion of *Node Split* has two new inserted nodes, which reflects the new string information that was found at the current position. The process splits the old node into two child nodes, and that is why this operation is called a "split."

19.3.3 Huffman Code Generation

Another major component of the compressor design is generation of the Huffman Code.

Huffman Coding is applied to the Char&Len Set, the Position Set, and the Extra Set. The Huffman Coding used here has the following features:

- The Huffman tree is represented as an array of code lengths ("canonical" Huffman Coding);
- The maximum code length is limited to 16 bits.

The Huffman code generation process can be divided into three steps. These are the generation of Huffman tree, the adjustment of code lengths, and the code generation.

19.3.3.1 Huffman Tree Generation

This process generates a typical Huffman tree. First, the frequency of each symbol is counted, and a list of nodes is generated with each node containing a symbol and the symbol's frequency. The two nodes with the lowest frequency values are merged into a single node. This new node becomes the parent node of the two nodes that are merged. The frequency value of this new parent node is the sum of the two child nodes' frequency values. The node list is updated to include the new parent node but exclude the two child nodes that are merged. This process is repeated until there is a single node remaining that is the root of the generated tree.

19.3.3.2 Code Length Adjustment

The leaf nodes of the tree generated by the previous step represent all the symbols that were generated. Traditionally the code for each symbol is found by traversing the tree from the root node to the leaf node. Going down a left edge generates a "0," and going down a right edge generates a "1." However, a different approach is used here. The number of codes of each code length is counted. This generates a 16-element LengthCount array, with LengthCount[i] = Number Of Codes whose Code Length is i. Since a code length may be longer than 16 bits, the sixteenth entry of the LengthCount array is set to the Number Of Codes whose Code Length is greater than or equal to 16.

The LengthCount array goes through further adjustment described by following code:

```
INT32 i, k;
UINT32 cum;

cum = 0;
for (i = 16; i > 0; i--) {
   cum += LengthCount[i] << (16 - i);
}
while (cum != (1U << 16)) {
 LengthCount[16]--;
 for (i = 15; i > 0; i--) {
   if (LengthCount[i] != 0) {
     LengthCount[i]--;
     LengthCount[i+1] += 2;
     break;
   }
 }
 cum--;
}
```

19.3.3.3 Code Generation

In the previous step, the count of each length was obtained. Now, each symbol is going to be assigned a code. First, the length of the code for each symbol is determined. Naturally, the code lengths are assigned in such a way that shorter codes are assigned to more frequently appearing symbols. A CodeLength array is generated with CodeLength[i] = the code length of symbol i. Given this array, a code is assigned to each symbol using the algorithm described by the pseudo code below (the resulting codes are stored in array Code such that Code[i] = the code assigned to symbol i):

```
INT32 i;
UINT16 Start[18];

Start[1] = 0;

for (i = 1; i <= 16; i++) {
  Start[i + 1] = (UINT16)((Start[i] + LengthCount[i]) << 1);
}

for (i = 0; i < NumberOfSymbols; i++) {
  Code[i] = Start[CodeLength[i]]++;
}
```

The code length adjustment process ensures that no code longer than the designated length will be generated. As long as the decompressor has the CodeLength array at hand, it can regenerate the codes.

19.4 Decompressor Design

The decompressor takes the compressed data as input and produces the original source data. The main tasks for the decompressor are decoding Huffman codes and restoring Pointers to the strings to which they point.

The following pseudo code describes the algorithm used in the design of a decompressor. The source code that illustrates an implementation of this design is listed in Appendix I.

```
WHILE not end of data DO
  IF at block boundary THEN
    Read in the Extra Set Code Length Array;
    Generate the Huffman code mapping table for the Extra Set;
    Read in and decode the Char&Len Set Code Length Array;
    Generate the Huffman code mapping table for the Char&Len Set;
    Read in the Position Set Code Length Array;
    Generate the Huffman code mapping table for the Position Set;
  ENDIF
  Get next code;
  Look the code up in the Char&Len Set code mapping table.
  Store the result as C;
  IF C < 256 (it represents an Original Character) THEN
    Output this character;
  ELSE (it represents a String Length)
    Transform C to be the actual String Length value;
    Get next code and look it up in the Position Set code mapping table, and
    with some additional transformation, store the result as P;
    Output C characters starting from the position "Current Position - P";
  ENDIF
ENDWHILE
```

19.5 Decompress Protocol

This section provides a detailed description of the *EFI_DECOMPRESS_PROTOCOL*.

19.5.1 EFI_DECOMPRESS_PROTOCOL

Summary

Provides a decompression service.

GUID

```
#define EFI_DECOMPRESS_PROTOCOL_GUID \
  {0xd8117cfe,0x94a6,0x11d4,\
    {0x9a,0x3a,0x00,0x90,0x27,0x3f,0xc1,0x4d}}
```

Protocol Interface Structure

```
typedef struct _EFI_DECOMPRESS_PROTOCOL {
  EFI_DECOMPRESS_GET_INFO             GetInfo;
  EFI_DECOMPRESS_DECOMPRESS           Decompress;
} EFI_DECOMPRESS_PROTOCOL;
```

Parameters

GetInfo
Given the compressed source buffer, this function retrieves the size of the uncompressed destination buffer and the size of the scratch buffer required to perform the decompression. It is the caller's responsibility to allocate the destination buffer and the scratch buffer prior to calling *EFI_DECOMPRESS_PROTOCOL.Decompress()* . See the *EFI_DECOMPRESS_PROTOCOL.GetInfo()* function description.

Decompress
Decompresses a compressed source buffer into an uncompressed destination buffer. It is the caller's responsibility to allocate the destination buffer and a scratch buffer prior to making this call. See the *Decompress()* function description.

Description

The *EFI_DECOMPRESS_PROTOCOL* provides a decompression service that allows a compressed source buffer in memory to be decompressed into a destination buffer in memory. It also requires a temporary scratch buffer to perform the decompression. The *GetInfo()* function retrieves the size of the destination buffer and the size of the scratch buffer that the caller is required to allocate. The *Decompress()* function performs the decompression. The scratch buffer can be freed after the decompression is complete.

19.5.2 EFI_DECOMPRESS_PROTOCOL.GetInfo()

Summary

Given a compressed source buffer, this function retrieves the size of the uncompressed buffer and the size of the scratch buffer required to decompress the compressed source buffer.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_DECOMPRESS_GET_INFO) (
  IN  EFI_DECOMPRESS_PROTOCOL        *This,
  IN  VOID                           *Source,
  IN  UINT32                         SourceSize,
  OUT UINT32                         *DestinationSize,
  OUT UINT32                         *ScratchSize
  );
```

Parameters

This

A pointer to the *EFI_DECOMPRESS_PROTOCOL* instance. Type EFI_DECOMPRESS_PROTOCOL is defined in *EFI_DECOMPRESS_PROTOCOL*.

Source

The source buffer containing the compressed data.

SourceSize

The size, in bytes, of the source buffer.

DestinationSize

A pointer to the size, in bytes, of the uncompressed buffer that will be generated when the compressed buffer specified by *Source* and *SourceSiz* e is decompressed.

ScratchSize

A pointer to the size, in bytes, of the scratch buffer that is required to decompress the compressed buffer specified by *Source* and *SourceSize*.

Description

The *GetInfo()* function retrieves the size of the uncompressed buffer and the temporary scratch buffer required to decompress the buffer specified by *Source* and *SourceSize*. If the size of the uncompressed buffer or the size of the scratch buffer cannot be determined from the compressed data specified by *Source* and *SourceData*, then *EFI_INVALID_PARAMETER* is returned. Otherwise, the size of the uncompressed buffer is returned in *DestinationSize*, the size of the scratch buffer is returned in *ScratchSize*, and *EFI_SUCCESS* is returned.

The *GetInfo()* function does not have scratch buffer available to perform a thorough checking of the validity of the source data. It just retrieves the "Original Size" field from the beginning bytes of the source data and output it as *DestinationSize*. And *ScratchSize* is specific to the decompression implementation.

Status Codes Returned

EFI_SUCCESS	The size of the uncompressed data was returned in *DestinationSize* and the size of the scratch buffer was returned in *ScratchSize*.
EFI_INVALID_PARAMETER	The size of the uncompressed data or the size of the scratch buffer cannot be determined from the compressed data specified by *Source* and *SourceSize*.

19.5.3 EFI_DECOMPRESS_PROTOCOL.Decompress()

Summary

Decompresses a compressed source buffer.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_DECOMPRESS_DECOMPRESS) (
  IN   EFI_DECOMPRESS_PROTOCOL      *This,
  IN    VOID                        *Source,
  IN    UINT32                      SourceSize,
  IN OUT VOID                       *Destination,
  IN    UINT32                      DestinationSize,
  IN OUT VOID                       *Scratch,
  IN    UINT32                      ScratchSize
  );
```

Parameters

This
A pointer to the *EFI_DECOMPRESS_PROTOCOL* instance. Type EFI_DECOMPRESS_PROTOCOL is defined in *EFI_DECOMPRESS_PROTOCOL*.

Source
The source buffer containing the compressed data.

SourceSize
The size of source data.

Destination
On output, the destination buffer that contains the uncompressed data.

DestinationSize
The size of the destination buffer. The size of the destination buffer needed is obtained from *EFI_DECOMPRESS_PROTOCOL.GetInfo()* .

Scratch
A temporary scratch buffer that is used to perform the decompression.

ScratchSize
The size of scratch buffer. The size of the scratch buffer needed is obtained from *GetInfo()*.

Description

The *Decompress()* function extracts decompressed data to its original form.

This protocol is designed so that the decompression algorithm can be implemented without using any memory services. As a result, the Decompress() function is not allowed to call *EFI_BOOT_SERVICES.AllocatePool()* or *EFI_BOOT_SERVICES.AllocatePages()* in its implementation. It is the caller's responsibility to allocate and free the Destination and Scratch buffers.

If the compressed source data specified by *Source* and *SourceSize* is successfully decompressed into *Destination*, then *EFI_SUCCESS* is returned. If the compressed source data specified by *Source* and *SourceSize* is not in a valid compressed data format, then *EFI_INVALID_PARAMETER* is returned.

Status Codes Returned

EFI_SUCCESS	Decompression completed successfully, and the uncompressed buffer is returned in *Destination*.
EFI_INVALID_PARAMETER	The source buffer specified by *Source* and *SourceSize* is corrupted (not in a valid compressed format).

CHAPTER

TWENTY

PROTOCOLS — ACPI PROTOCOLS

20.1 EFI_ACPI_TABLE_PROTOCOL

Summary

This protocol may be used to install or remove an ACPI table from a platform.

GUID

```
#define EFI_ACPI_TABLE_PROTOCOL_GUID \
  {0xffe06bdd, 0x6107, 0x46a6,\
    {0x7b, 0xb2, 0x5a, 0x9c, 0x7e, 0xc5, 0x27, 0x5c}}
```

Protocol Interface Structure

```
typedef struct _EFI_ACPI_TABLE_PROTOCOL {
  EFI_ACPI_TABLE_INSTALL_ACPI_TABLE       InstallAcpiTable;
  EFI_ACPI_TABLE_UNINSTALL_ACPI_TABLE     UninstallAcpiTable;
}  EFI_ACPI_TABLE_PROTOCOL;
```

Parameters

InstallAcpiTable
Installs an ACPI table into the system.

UninstallAcpiTable
Removes a previously installed ACPI table from the system.

Description

The *EFI_ACPI_TABLE_PROTOCOL* provides the ability for a component to install and uninstall ACPI tables from a platform.

20.2 EFI_ACPI_TABLE_PROTOCOL.InstallAcpiTable()

Summary

Installs an ACPI table into the RSDT/XSDT.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_ACPI_TABLE_INSTALL_ACPI_TABLE) (
  IN EFI_ACPI_TABLE_PROTOCOL                    *This,
  IN VOID                                       *AcpiTableBuffer,
  IN UINTN                                      AcpiTableBufferSize,
  OUT UINTN                                     *TableKey,
  );
```

Parameters

This
A pointer to a *EFI_ACPI_TABLE_PROTOCOL* .

AcpiTableBuffer
A pointer to a buffer containing the ACPI table to be installed.

AcpiTableBufferSize
Specifies the size, in bytes, of the *AcpiTableBuffer* buffer.

TableKey
Returns a key to refer to the ACPI table.

Description

The *InstallAcpiTable()* function allows a caller to install an ACPI table. The ACPI table may either by a System Description Table or the FACS. For all tables except for the DSDT and FACS, a copy of the table will be linked by the RSDT/XSDT. For the FACS and DSDT, the pointer to a copy of the table will be updated in the FADT, if present.

To prevent namespace collision, ACPI tables may be created using UEFI ACPI table format, *Appendix O — UEFI ACPI Data Table*. If this protocol is used to install a table with a signature already present in the system, the new table will not replace the existing table. It is a platform implementation decision to add a new table with a signature matching an existing table or disallow duplicate table signatures and return *EFI_ACCESS_DENIED*.

On successful output, *TableKey* is initialized with a unique key. Its value may be used in a subsequent call to *UninstallAcpiTable* to remove an ACPI table.

On successful output, the *EFI_ACPI_TABLE_PROTOCOL* will ensure that the checksum field is correct for both the RSDT/XSDT table and the copy of the table being installed that is linked by the RSDT/XSDT.

On successful completion, this function reinstalls the relevant *EFI_CONFIGURATION_TABLE* pointer to the RSDT.

Status Codes Returned

EFI_SUCCESS	The table was successfully inserted
EFI_INVALID_PARAMETER	The *AcpiTableBuffer* is *NULL* , the *TableKey* is *NULL* ;the *AcpiTableBufferSize* , and the size field embedded in the ACPI table pointed to by *AcpiTableBuffer* are not in sync.
EFI_OUT_OF_RESOURCES	Insufficient resources exist to complete the request.
EFI_ACCESS_DENIED	The table signature matches a table already present in the system and platform policy does not allow duplicate tables of this type.

20.3 EFI_ACPI_TABLE_PROTOCOL.UninstallAcpiTable()

Summary

Removes an ACPI table from the RSDT/XSDT.

Prototype

```
typedef
EFI_STATUS
(EFIAPI *EFI_ACPI_TABLE_UNINSTALL_ACPI_TABLE) (
  IN EFI_ACPI_TABLE_PROTOCOL             *This,
  IN UINTN                               TableKey,
  );
```

Parameters

This

A pointer to a *EFI_ACPI_TABLE_PROTOCOL* .

TableKey

Specifies the table to uninstall. The key was returned from *InstallAcpiTable()*.

Description

The *UninstallAcpiTable()* function allows a caller to remove an ACPI table. The routine will remove its reference from the RSDT/XSDT. A table is referenced by the TableKey parameter returned from a prior call to *InstallAcpiTable()*.

On successful completion, this function reinstalls the relevant *EFI_CONFIGURATION_TABLE* pointer to the RSDT.

Status Codes Returned

EFI_SUCCESS	The table was successfully inserted
EFI_NOT_FOUND	TableKey does not refer to a valid key for a table entry.
EFI_OUT_OF_RESOURCES	Insufficient resources exist to complete the request.

CHAPTER

TWENTYONE

PROTOCOLS — STRING SERVICES

21.1 Unicode Collation Protocol

This section defines the Unicode Collation protocol. This protocol is used to allow code running in the boot services environment to perform lexical comparison functions on Unicode strings for given languages.

21.1.1 EFI_UNICODE_COLLATION_PROTOCOL

Summary

Is used to perform case-insensitive comparisons of strings.

GUID

```
#define EFI_UNICODE_COLLATION_PROTOCOL2_GUID \
  {0xa4c751fc, 0x23ae, 0x4c3e, \
    {0x92, 0xe9, 0x49, 0x64, 0xcf, 0x63, 0xf3, 0x49}}
```

Protocol Interface Structure

```
typedef struct {
  EFI_UNICODE_COLLATION_STRICOLL         StriColl;
  EFI_UNICODE_COLLATION_METAIMATCH       MetaiMatch;
  EFI_UNICODE_COLLATION_STRLWR           StrLwr;
  EFI_UNICODE_COLLATION_STRUPR           StrUpr;
  EFI_UNICODE_COLLATION_FATTOSTR         FatToStr;
  EFI_UNICODE_COLLATION_STRTOFAT         StrToFat;
  CHAR8                                  *SupportedLanguages;
} EFI_UNICODE_COLLATION_PROTOCOL;
```

Parameters

StriColl

Performs a case-insensitive comparison of two Null-terminated strings. See the *EFI_UNICODE_COLLATION_PROTOCOL.StriColl()* function description.

MetaiMatch

Performs a case-insensitive comparison between a Null-terminated pattern string and a Null-terminated string. The pattern string can use the '?' wildcard to match any character, and the '*' wildcard to match any substring. See the *EFI_UNICODE_COLLATION_PROTOCOL.MetaiMatch()* function description.

StrLwr

Converts all the characters in a Null-terminated string to lowercase characters. See the *EFI_UNICODE_COLLATION_PROTOCOL.StrLwr()* function description.

StrUpr

Converts all the characters in a Null-terminated string to uppercase characters. See the *EFI_UNICODE_COLLATION_PROTOCOL.StrUpr()* function description.

FatToStr

Converts an 8.3 FAT file name using an OEM character set to a Null-terminated string. See the *EFI_UNICODE_COLLATION_PROTOCOL.FatToStr()* function description.

StrToFat

Converts a Null-terminated string to legal characters in a FAT filename using an OEM character set. See the *EFI_UNICODE_COLLATION_PROTOCOL.StrToFat()* function description.

SupportedLanguages

A Null-terminated ASCII string array that contains one or more language codes. This array is specified in RFC 4646 format. See *Appendix M — Formats — Language Codes and Language Code Arrays*

Description

The EFI_UNICODE_COLLATION_PROTOCOL is used to perform case-insensitive comparisons of strings.

One or more of the EFI_UNICODE_COLLATION_PROTOCOL instances may be present at one time. Each protocol instance can support one or more language codes. The language codes supported in the EFI_UNICODE_COLLATION_PROTOCOL are declared in *SupportedLanguages* .

The *SupportedLanguages* is a Null-terminated ASCII string array that contains one or more supported language codes. This is the list of language codes that this protocol supports. See *Appendix M — Formats — Language Codes and Language Code Arrays* for the format of language codes and language code arrays.

The main motivation for this protocol is to help support file names in a file system driver. When a file is opened, a file name needs to be compared to the file names on the disk. In some cases, this comparison needs to be performed in a case-insensitive manner. In addition, this protocol can be used to sort files from a directory or to perform a case-insensitive file search.

21.1.2 EFI_UNICODE_COLLATION_PROTOCOL.StriColl()

Summary

Performs a case-insensitive comparison of two Null-terminated strings.

Prototype

```
typedef
INTN
(EFIAPI *EFI_UNICODE_COLLATION_STRICOLL) (
  IN EFI_UNICODE_COLLATION_PROTOCOL    *This,
  IN CHAR16                            *s1,
  IN CHAR16                            *s2
  );
```

Parameters

This

A pointer to the *EFI_UNICODE_COLLATION_PROTOCOL* instance. Type EFI_UNICODE_COLLATION_PROTOCOL is defined above.

s1

A pointer to a Null-terminated string.

s2

A pointer to a Null-terminated string.

Description

The StriColl() function performs a case-insensitive comparison of two Null-terminated strings.

This function performs a case-insensitive comparison between the string s1 and the string s2 using the rules for the language codes that this protocol instance supports. If s1 is equivalent to s2, then 0 is returned. If s1 is lexically less than s2, then a negative number will be returned. If s1 is lexically greater than s2, then a positive number will be returned. This function allows strings to be compared and sorted.

Status Codes Returned

0	s1 is equivalent to s2.
> 0	s1 is lexically greater than s2.
< 0	s1 is lexically less than s2.

21.1.3 EFI_UNICODE_COLLATION_PROTOCOL.MetaiMatch()

Summary

Performs a case-insensitive comparison of a Null-terminated pattern string and a Null-terminated string.

Prototype

```
typedef
BOOLEAN
(EFIAPI *EFI_UNICODE_COLLATION_METAIMATCH) (
  IN EFI_UNICODE_COLLATION_PROTOCOL       *This,
  IN CHAR16                               *String,
  IN CHAR16                               *Pattern
  );
```

Parameters

This

A pointer to the *EFI_UNICODE_COLLATION_PROTOCOL* instance. Type EFI_UNICODE_COLLATION_PROTOCOL is defined above.

String

A pointer to a Null-terminated string.

Pattern

A pointer to a Null-terminated string.

Description

The *MetaiMatch()* function performs a case-insensitive comparison of a Null-terminated pattern string and a Null-terminated string.

This function checks to see if the pattern of characters described by *Pattern* are found in *String* . The pattern check is a case-insensitive comparison using the rules for the language codes that this protocol instance supports. If the pattern match succeeds, then **TRUE** is returned. Otherwise **FALSE** is returned. The following syntax can be used to build the string Pattern:

```
*                             Match 0 or more characters.
?                             Match any one character.
[<char1><char2>...<charN>]    Match any character in the set.
[<char1>-<char2>]             Match any character between <char1> and<char2>.
<char>                        Match the character <char>.
```

Following is an example pattern for English:

```
*.FW                          Matches all strings that end in ".FW" or .fw" or ".Fw" or
↪".fW."
[a-z]                         Match any letter in the alphabet.
[!@#$%^&*()]                  Match any one of these symbols.
z                             Match the character "z" or "Z."
D?.*                          Match the character "D" or "d"
                              followed by any character
                              followed by a "." followed by any string.
```

Status Codes Returned

TRUE	Pattern was found in String.
FALSE	Pattern was not found in String.

21.1.4 EFI_UNICODE_COLLATION_PROTOCOL.StrLwr()

Summary

Converts all the characters in a Null-terminated string to lowercase characters.

Prototype

```
typedef
VOID
(EFIAPI *EFI_UNICODE_COLLATION_STRLWR) (
  IN EFI_UNICODE_COLLATION_PROTOCOL       *This,
  IN OUT CHAR16                           *String
  );
```

Parameters

This

A pointer to the *EFI_UNICODE_COLLATION_PROTOCOL* instance. Type EFI_UNICODE_COLLATION_PROTOCOL is defined above.

String

A pointer to a Null-terminated string.

Description

This function walks through all the characters in *String,* and converts each one to its lowercase equivalent if it has one. The converted string is returned in *String* .

21.1.5 EFI_UNICODE_COLLATION_PROTOCOL.StrUpr()

Summary

Converts all the characters in a Null-terminated string to uppercase characters.

Prototype

```
typedef
VOID
(EFIAPI *EFI_UNICODE_COLLATION_STRUPR) (
  IN EFI_UNICODE_COLLATION_PROTOCOL      *This,
  IN OUT CHAR16                          *String
  );
```

Parameters

This

A pointer to the *EFI_UNICODE_COLLATION_PROTOCOL* instance. Type EFI_UNICODE_COLLATION_PROTOCOL is defined above.

String

A pointer to a Null-terminated string.

Description

This functions walks through all the characters in *String*, and converts each one to its uppercase equivalent if it has one. The converted string is returned in *String* .

21.1.6 EFI_UNICODE_COLLATION_PROTOCOL.FatToStr()

Summary

Converts an 8.3 FAT file name in an OEM character set to a Null-terminated string.

Prototype

```
typedef
VOID
(EFIAPI *EFI_UNICODE_COLLATION_FATTOSTR) (
  IN EFI_UNICODE_COLLATION_PROTOCOL       *This,
  IN UINTN                                FatSize,
  IN CHAR8                                *Fat,
  OUT CHAR16                              *String
  );
```

Parameters

This

A pointer to the *EFI_UNICODE_COLLATION_PROTOCOL* instance. Type EFI_UNICODE_COLLATION_PROTOCOL is defined above.

FatSize

The size of the string Fat in bytes.

Fat

A pointer to a Null-terminated string that contains an 8.3 file name encoded using an 8-bit OEM character set.

String

A pointer to a Null-terminated string. The string must be allocated in advance to hold *FatSize* characters.

Description

This function converts the string specified by *Fat* with length *FatSize* to the Null-terminated string specified by *String* . The characters in *Fat* are from an OEM character set.

21.1.7 EFI_UNICODE_COLLATION_PROTOCOL.StrToFat()

Summary

Converts a Null-terminated string to legal characters in a FAT filename using an OEM character set.

Prototype

```
typedef
BOOLEAN
(EFIAPI *EFI_UNICODE_COLLATION_STRTOFAT) (
  IN EFI_UNICODE_COLLATION_PROTOCOL       *This,
  IN CHAR16                               *String,
  IN UINTN                                FatSize,
  OUT CHAR8                               *Fat
  );
```

Parameters

This

A pointer to the *EFI_UNICODE_COLLATION_PROTOCOL* instance. Type EFI_UNICODE_COLLATION_PROTOCOL is defined above.

String

A pointer to a Null-terminated string.

FatSize

The size of the string Fat in bytes.

Fat

A pointer to a string that contains the converted version of *String* using legal FAT characters from an OEM character set.

Description

This function converts the characters from *String* into legal FAT characters in an OEM character set and stores then in the string *Fat* . This conversion continues until either *FatSize* bytes are stored in *Fat,* or the end of *String* is reached. The characters '.' (period) and ' ' (space) are ignored for this conversion. Characters that map to an illegal FAT character are substituted with an '_'. If no valid mapping from a character to an OEM character is available, then it is also substituted with an '_'. If any of the character conversions are substituted with a '_', then **TRUE** is returned. Otherwise **FALSE** is returned.

Status Codes Returned

TRUE	One or more conversions failed and were substituted with '_'.
FALSE	None of the conversions failed.

21.2 Regular Expression Protocol

This section defines the Regular Expression Protocol. This protocol is used to match Unicode strings against Regular Expression patterns.

21.2.1 EFI_REGULAR_EXPRESSION_PROTOCOL

Summary

GUID

```
#define EFI_REGULAR_EXPRESSION_PROTOCOL_GUID \
  { 0xB3F79D9A, 0x436C, 0xDC11,\
    { 0xB0, 0x52, 0xCD, 0x85, 0xDF, 0x52, 0x4C, 0xE6 } }
```

Protocol Interface Structure

```
typedef struct {
  EFI_REGULAR_EXPRESSION_MATCH      MatchString;
  EFI_REGULAR_EXPRESSION_GET_INFO   GetInfo;
} EFI_REGULAR_EXPRESSION_PROTOCOL;
```

Parameters

MatchString
Search the input string for anything that matches the regular expression.

GetInfo
Returns information about the regular expression syntax types supported by the implementation.

21.2.2 EFI_REGULAR_EXPRESSION_PROTOCOL.MatchString()

Summary

Checks if the input string matches to the regular expression pattern.

Prototype

```
typedef
EFI_STATUS
EFIAPI *EFI_REGULAR_EXPRESSION_MATCH) (
  IN   EFI_REGULAR_EXPRESSION_PROTOCOL *This,
  IN   CHAR16                          *String,
  IN   CHAR16                          *Pattern,
  IN   EFI_REGEX_SYNTAX_TYPE           *SyntaxType, OPTIONAL
  OUT  BOOLEAN                         *Result,
  OUT  EFI_REGEX_CAPTURE               **Captures, OPTIONAL
  OUT UINTN                            *CapturesCount
  );
```

Parameters

This
A pointer to the *EFI_REGULAR_EXPRESSION_PROTOCOL* instance. Type EFI_REGULAR_EXPRESSION_PROTOCOL is defined in above.

String

A pointer to a NULL terminated string to match against the regular expression string specified by *Pattern* .

Pattern

A pointer to a NULL terminated string that represents the regular expression.

SyntaxType

A pointer to the EFI_REGEX_SYNTAX_TYPE that identifies the regular expression syntax type to use. May be NULL in which case the function will use its default regular expression syntax type.

Result

On return, points to TRUE if String fully matches against the regular expression Pattern using the regular expression SyntaxType . Otherwise, points to FALSE .

Captures

A Pointer to an array of EFI_REGEX_CAPTURE objects to receive the captured groups in the event of a match. The full sub-string match is put in Captures [0], and the results of N capturing groups are put in Captures [1:N]. If Captures is NULL, then this function doesn't allocate the memory for the array and does not build up the elements. It only returns the number of matching patterns in CapturesCount . If Captures is not NULL, this function returns a pointer to an array and builds up the elements in the array. CapturesCount is also updated to the number of matching patterns found. It is the caller's responsibility to free the memory pool in Captures and in each CapturePtr in the array elements.

CapturesCount

On output, CapturesCount is the number of matching patterns found in String. Zero means no matching patterns were found in the string.

Description

The MatchString() function performs a matching of a Null-terminated input string with the NULL terminated pattern string. The pattern string syntax type is optionally identified in SyntaxType .

This function checks to see if String fully matches against the regular expression described by Pattern. The pattern check is performed using regular expression rules that are supported by this implementation, as indicated in the return value of GetInfo function. If the pattern match succeeds, then TRUE is returned in Result . Otherwise FALSE is returned.

Related Definitions

```
typedef struct {
  CONST CHAR16       *CapturePtr;
  UINTN              Length;
}  EFI_REGEX_CAPTURE;
```

***CapturePtr**

Pointer to the start of the captured sub-expression within matched String.

Length

Length of captured sub-expression.

Status Codes Returned

EFI_SUCCESS	The regular expression string matching completed successfully.
EFI_UNSUPPORTED	The regular expression syntax specified by *SyntaxType* is not supported by this driver.
EFI_DEVICE_ERROR	The regular expression string matching failed due to a hardware or firmware error.
EFI_INVALID_PARAMETER	String, Pattern, Result, or CapturesCount is NULL.

21.2.3 EFI_REGULAR_EXPRESSION_PROTOCOL.GetInfo()

Summary

Returns information about the regular expression syntax types supported by the implementation.

Prototype

```
typedef
EFI_STATUS
EFIAPI *EFI_REGULAR_EXPRESSION_GET_INFO) (
  IN EFI_REGULAR_EXPRESSION_PROTOCOL        *This,
  IN OUT UINTN                              *RegExSyntaxTypeListSize,
  OUT EFI_REGEX_SYNTAX_TYPE                 *RegExSyntaxTypeList
  );
```

Parameters

This

A pointer to the *EFI_REGULAR_EXPRESSION_PROTOCOL* instance.

RegExSyntaxTypeListSize

On input, the size in bytes of *RegExSyntaxTypeList* . *On* output with a return code of *EFI_SUCCESS* , *th* e size in bytes of the data returned in *RegExSyntaxTypeList* . On output with a return code of *EFI_BUFFER_TOO_SMALL*, the size of *RegExSyntaxTypeList* required to obtain the list.

RegExSyntaxTypeList

A caller-allocated memory buffer filled by the driver with one *EFI_REGEX_SYNTAX_TYPE* element for each supported regular expression syntax type. The list must not change across multiple calls to the same driver. The first syntax type in the list is the default type for the driver.

Description

This function returns information about supported regular expression syntax types. A driver implementing the *EFI_REGULAR_EXPRESSION_PROTOCOL* need not support more than one regular expression syntax type, but shall support a minimum of one regular expression syntax type.

Related Definitions

```
typedef EFI_GUID EFI_REGEX_SYNTAX_TYPE;
```

Status Codes Returned

EFI_SUCCESS	The regular expression syntax types list was returned successfully.
EFI_UNSUPPORTED	The service is not supported by this driver.
EFI_DEVICE_ERROR	The list of syntax types could not be retrieved due to a hardware or firmware error.
EFI_BUFFER_TOO_SMALL	The buffer *RegExSyntaxTypeList* is too small to hold the result.
EFI_INVALID_PARAMETER	*RegExSyntaxTypeListSize* is NULL.

21.2.4 EFI Regular Expression Syntax Type Definitions

Summary

This sub-section provides EFI_GUID values for a selection of EFI_REGULAR_EXPRESSION_PROTOCOL syntax types. The types listed are optional, not meant to be exhaustive and may be augmented by vendors or other industry standards.

Prototype

For regular expression rules specified in the POSIX Extended Regular Expression (ERE) Syntax:

```
#define EFI_REGEX_SYNTAX_TYPE_POSIX_EXTENDED_GUID \
  {0x5F05B20F, 0x4A56, 0xC231,\
    { 0xFA, 0x0B, 0xA7, 0xB1, 0xF1, 0x10, 0x04, 0x1D }}
```

For regular expression rules specified in the Perl standard:

```
#define EFI_REGEX_SYNTAX_TYPE_PERL_GUID \
  {0x63E60A51, 0x497D, 0xD427,\
   { 0xC4, 0xA5, 0xB8, 0xAB, 0xDC, 0x3A, 0xAE, 0xB6 }}
```

For regular expression rules specified in the ECMA 262 Specification:

```
#define EFI_REGEX_SYNTAX_TYPE_ECMA_262_GUID \
  { 0x9A473A4A, 0x4CEB, 0xB95A, 0x41,\
    { 0x5E, 0x5B, 0xA0, 0xBC, 0x63, 0x9B, 0x2E }}
```

For regular expression rules specified in the POSIX Extended Regular Expression (ERE) Syntax, where the Pattern and String input strings need to be converted to ASCII:

```
#define EFI_REGEX_SYNTAX_TYPE_POSIX_EXTENDED_ASCII_GUID \
  {0x3FD32128, 0x4BB1, 0xF632, \
    { 0xBE, 0x4F, 0xBA, 0xBF, 0x85, 0xC9, 0x36, 0x76 }}
```

For regular expression rules specified in the Perl standard, where the Pattern and String input strings nees to be converted to ASCII:

```
#define EFI_REGEX_SYNTAX_TYPE_PERL_ASCII_GUID \
  {0x87DFB76D, 0x4B58, 0xEF3A, \
    { 0xF7, 0xC6, 0x16, 0xA4, 0x2A, 0x68, 0x28, 0x10 }}
```

For regular expression rules specified in the ECMA 262 Specification, where the Pattern and String input strings need to be converted to ASCII:

```
#define EFI_REGEX_SYNTAX_TYPE_ECMA_262_ASCII_GUID \
  { 0xB2284A2F, 0x4491, 0x6D9D, \
    { 0xEA, 0xB7, 0x11, 0xB0, 0x67, 0xD4, 0x9B, 0x9A }}
```

See *Appendix Q — References* for more information.

CHAPTER

TWENTYTWO

EFI BYTE CODE VIRTUAL MACHINE

This section defines an EFI Byte Code (EBC) Virtual Machine that can provide platform- and processor-independent mechanisms for loading and executing EFI device drivers.

22.1 Overview

The current design for option ROMs that are used in personal computer systems has been in place since 1981. Attempts to change the basic design requirements have failed for a variety of reasons. The EBC Virtual Machine described in this chapter is attempting to help achieve the following goals:

- Abstract and extensible design
- Processor independence
- OS independence
- Build upon existing specifications when possible
- Facilitate the removal of legacy infrastructure
- Exclusive use of EFI Services

One way to satisfy many of these goals is to define a pseudo or virtual machine that can interpret a predefined instruction set. This will allow the virtual machine to be ported across processor and system architectures without changing or recompiling the option ROM. This specification defines a set of machine level instructions that can be generated by a C compiler.

The following sections are a detailed description of the requirements placed on future option ROMs.

22.1.1 Processor Architecture Independence

Option ROM images shall be independent of supported 32-bit and supported 64-bit architectures. In order to abstract the architectural differences between processors option ROM images shall be EBC. This model is presented below:

- 64-bit C source code
- The EFI EBC image is the flashed image
- The system BIOS implements the EBC interpreter
- The interpreter handles 32 vs. 64 bit issues

Current Option ROM technology is processor dependent and heavily reliant upon the existence of the PC-AT infrastructure. These dependencies inhibit the evolution of both hardware and software under the veil of “backward compatibility.” A solution that isolates the hardware and support infrastructure through abstraction will facilitate the uninhibited progression of technology.

22.1.2 OS Independent

Option ROMs shall not require or assume the existence of a particular OS.

22.1.3 EFI Compliant

Option ROM compliance with EFI requires (but is not limited to) the following:

- Little endian layout
- Single-threaded model with interrupt polling if needed
- Where EFI provides required services, EFI is used exclusively. These include:
  - Console I/O
  - Memory Management
  - Timer services
  - Global variable access
- When an Option ROM provides EFI services, the EFI specification is strictly followed:
  - Service/protocol installation
  - Calling conventions
  - Data structure layouts
  - Guaranteed return on services

22.1.4 Coexistence of Legacy Option ROMs

The infrastructure shall support coexistent Legacy Option ROM and EBC Option ROM images. This case would occur, for example, when a Plug and Play Card has both Legacy and EBC Option ROM images flashed. The details of the mechanism used to select which image to load is beyond the scope of this document. Basically, a legacy System BIOS would not recognize an EBC Option ROM and therefore would never load it. Conversely, an EFI Firmware Boot Manager would only load images that it supports.

The EBC Option ROM format must utilize a legacy format to the extent that a Legacy System BIOS can:

- Determine the type of the image, in order to ignore the image. The type must be incompatible with currently defined types.
- Determine the size of the image, in order to skip to the next image.

22.1.5 Relocatable Image

An EBC option ROM image shall be eligible for placement in any system memory area large enough to accommodate it.

Current option ROM technology requires images to be shadowed in system memory address range 0xC0000 to 0xEFFFF on a 2048 byte boundary. This dependency not only limits the number of Option ROMs, it results in unused memory fragments up to 2 KiB.

22.1.6 Size Restrictions Based on Memory Available

EBC option ROM images shall not be limited to a predetermined fixed maximum size.

Current option ROM technology limits the size of a preinitialization option ROM image to 128 KiB (126 KiB actual). Additionally, in the DDIM an image is not allowed to grow during initialization. It is inevitable that 64-bit solutions will increase in complexity and size. To avoid revisiting this issue, EBC option ROM size is only limited by available system memory. EFI memory allocation services allow device drivers to claim as much memory as they need, within limits of available system memory.

The PCI specification limits the size of an image stored in an option ROM to 16 MB. If the driver is stored on the hard drive then the 16MB option ROM limit does not apply. In addition, the PE/COFF object format limits the size of images to 2 GB.

22.2 Memory Ordering

The term memory ordering refers to the order in which a processor issues reads (loads) and writes (stores) out onto the bus to system memory. The EBC Virtual Machine enforces strong memory ordering, where reads and writes are issued on the system bus in the order they occur in the instruction stream under all circumstances.

22.3 Virtual Machine Registers

The EBC virtual machine utilizes a simple register set. There are two categories of VM registers: general purpose registers and dedicated registers. All registers are 64-bits wide. There are eight (8) general-purpose registers (R0-R7), which are used by most EBC instructions to manipulate or fetch data. The Table below, *General Purpose VM Registers* , lists the general-purpose registers in the VM and the conventions for their usage during execution.

Table 22.1: General Purpose VM Registers

Index	Register	Description
0	R0	Points to the top of the stack
1-3	R1-R3	Preserved across calls
4-7	R4-R7	Scratch, not preserved across calls

Register R0 is used as a stack pointer and is used by the *CALL* , *RET* , *PUSH* , and *POP* instructions. The VM initializes this register to point to the incoming arguments when an EBC image is started or entered. This register may be modified like any other general purpose VM register using EBC instructions. Register R7 is used for function return values.

Unlike the general-purpose registers, the VM dedicated registers have specific purposes. There are two dedicated registers: the instruction pointer (IP), and the flags (Flags) register. Specialized instructions provide access to the dedicated registers. These instructions reference the particular dedicated register by its assigned index value. *Dedicated VM Registers* lists the dedicated registers and their corresponding index values.

Table 22.2: Dedicated VM Registers

Index	Register	Description
0	FLAGS	
		Bit | Description

continues on next page

Table 22.2 – continued from previous page

		0 | C = Condition code
		1 | SS = Single step
		2..63 | Reserved
1	IP	Points to current instruction
2..7	Reserved	Not defined

The VM Flags register contains VM status and context flags. *VM Flags Register* lists the descriptions of the bits in the Flags register.

Table 22.3: VM Flags Register

Bit	Flag	Description
0	C	Condition code. Set to 1 if the result of the last compare was **TRUE**, or set to 0 if the last compare was **FALSE**. Used by conditional JMP instructions.
1	S	Single-step. If set, causes the VM to generate a single-step exception after executing each instruction. The bit is not cleared by the VM following the exception.
2..63	—	Reserved

The VM IP register is used as an instruction pointer and holds the address of the currently executing EBC instruction. The virtual machine will update the IP to the address of the next instruction on completion of the current instruction, and will continue execution from the address indicated in IP. The IP register can be moved into any general-purpose register (R0-R7). Data manipulation and data movement instructions can then be used to manipulate the value. The only instructions that may modify the IP are the *JMP* , *CALL* , and *RET* instructions. Since the instruction set is designed to use words as the minimum instruction entity, the low order bit (bit 0) of IP is always cleared to 0. If a JMP, CALL, or RET instruction causes bit 0 of IP to be set to 1, then an alignment exception occurs.

22.4 Natural Indexing

The natural indexing mechanism is the critical functionality that enables EBC to be executed unchanged on 32- or 64-bit systems. Natural indexing is used to specify the offset of data relative to a base address. However, rather than specifying the offset as a fixed number of bytes, the offset is encoded in a form that specifies the actual offset in two parts: a constant offset, and an offset specified as a number of natural units (where one natural unit = sizeof (VOID *)). These two values are used to compute the actual offset to data at runtime. When the VM decodes an index during execution, the resultant offset is computed based on the natural processor size. The encoded indexes themselves may be 16, 32, or 64 bits in size. The Table below describes the fields in a natural index encoding.

Table 22.4: Index Encoding

Bit #	Description
N	Sign bit (sign), most significant bit
N-3..N-1	Bits assigned to natural units (w)
A..N-4	Constant units (c)
0..A-1	Natural units (n)

As shown in the Table above for a given encoded index, the most significant bit (bit N) specifies the sign of the resultant offset after it has been calculated. The sign bit is followed by three bits (N-3..N-1) that are used to compute the width of the natural units field (n). The value (w) from this field is multiplied by the index size in bytes to determine the actual width (A) of the natural units field (n). Once the width of the natural units field has been determined, then the natural units (n) and constant units (c) can be extracted. The offset is then calculated at runtime according to the following equation:

```
Offset = (c + n * (sizeof (VOID *))) * sign
```

The following sections describe each of these fields in more detail.

22.4.1 Sign Bit

The sign bit determines the sign of the index once the offset calculation has been performed. All index computations using "n" and "c" are done with positive numbers, and the sign bit is only used to set the sign of the final offset computed.

22.4.2 Bits Assigned to Natural Units

This 3-bit field that is used to determine the width of the natural units field. The units vary based on the size of the index according to the Table, below, *Index Size in Index Encoding* . For example, for a 16-bit index, the value contained in this field would be multiplied by 2 to get the actual width of the natural-units field.

Table 22.5: Index Size in Index Encoding

Index Size	Units
16 bits	2 bits
32 bits	4 bits
64 bits	8 bits

22.4.3 Constant

The constant is the number of bytes in the index that do not scale with processor size. When the index is a 16-bit value, the maximum constant is 4095. This index is achieved when the bits assigned to natural units is 0.

22.4.4 Natural Units

Natural units are used when a structure has fields that can vary with the architecture of the processor. Fields that precipitate the use of natural units include pointers and EFI INTN and UINTN data types. The size of one pointer or INTN/UINTN equals one natural unit. The natural units field in an index encoding is a count of the number of natural fields whose sizes (in bytes) must be added to determine a field offset.

As an example, assume that a given EBC instruction specifies a 16-bit index of 0xA048. This breaks down into:

- Sign bit (bit 15) = 1 (negative offset)
- Bits assigned to natural units (w, bits 14-12) = 2. Multiply by index size in bytes = 2 x 2 = 4 (A)
- c = bits 11-4 = 4
- n = bits 3-0 = 8

On a 32-bit machine, the offset is then calculated to be:

- Offset = (4 + 8 * 4) * -1 = -36
- On a 64-bit machine, the offset is calculated to be:
- Offset = (4 + 8 * 8) * -1 = -68

22.5 EBC Instruction Operands

The VM supports an EBC instruction set that performs data movement, data manipulation, branching, and other miscellaneous operations typical of a simple processor. Most instructions operate on two operands, and have the general form:

```
INSTRUCTION Operand1, Operand2
```

Typically, instruction operands will be one of the following:

- Direct
- Indirect
- Indirect with index
- Immediate

The following subsections explain these operands.

22.5.1 Direct Operands

When a direct operand is specified for an instruction, the data to operate upon is contained in one of the VM general-purpose registers R0-R7. Syntactically, an example of direct operand mode could be the *ADD* instruction:

```
ADD64 R1, R2
```

This form of the instruction utilizes two direct operands. For this particular instruction, the VM would take the contents of register R2, add it to the contents of register R1, and store the result in register R1.

22.5.2 Indirect Operands

When an indirect operand is specified, a VM register contains the address of the operand data. This is sometimes referred to as register indirect, and is indicated by prefixing the register operand with "@." Syntactically, an example of an indirect operand mode could be this form of the ADD instruction:

```
ADD32 R1, @R2
```

For this instruction, the VM would take the 32-bit value at the address specified in R2, add it to the contents of register R1, and store the result in register R1.

22.5.3 Indirect with Index Operands

When an indirect with index operand is specified, the address of the operand is computed by adding the contents of a register to a decoded natural index that is included in the instruction. Typically with indexed addressing, the base address will be loaded in the register and an index value will be used to indicate the offset relative to this base address. Indexed addressing takes the form:

@ R_1(+n,+c)

where:

- R_1 is one of the general-purpose registers (R0-R7) which contains the base address
- +n is a count of the number of "natural" units offset. This portion of the total offset is computed at runtime as (n * sizeof (VOID *))

- +c is a byte offset to add to the natural offset to resolve the total offset

The values of n and c can be either positive or negative, though they must both have the same sign. These values get encoded in the indexes associated with EBC instructions as shown in *Index Encoding*. Indexes can be 16-, 32-, or 64-bits wide depending on the instruction. An example of indirect with index syntax would be:

```
ADD32 R1, @R2 (+1, +8)
```

This instruction would take the address in register R2, add (8 + 1 * sizeof (VOID *)), read the 32-bit value at the address, add the contents of R1 to the value, and store the result back to R1.

22.5.4 Immediate Operands

Some instructions support an immediate operand, which is simply a value included in the instruction encoding. The immediate value may or may not be sign extended, depending on the particular instruction. One instruction that supports an immediate operand is *MOVI* . An example usage of this instruction is:

```
MOVIww R1, 0x1234
```

This instruction moves the immediate value 0x1234 directly into VM register R1. The immediate value is contained directly in the encoding for the MOVI instruction.

22.6 EBC Instruction Syntax

Most EBC instructions have one or more variations that modify the size of the instruction and/or the behavior of the instruction itself. These variations will typically modify an instruction in one or more of the following ways:

- The size of the data being operated upon
- The addressing mode for the operands
- The size of index or immediate data
- To represent these variations syntactically in this specification the following conventions are used:
- Natural indexes are indicated with the “Index” keyword, and may take the form of “Index16,” “Index32,” or “Index64” to indicate the size of the index value supported. Sometimes the form Index16|32|64 is used here, which is simply a shorthand notation for Index16|Index32|Index64. A natural index is encoded per *Index Encoding* is resolved at runtime.
- Immediate values are indicated with the “Immed” keyword, and may take the form of “Immed16,” “Immed32,” or “Immed64” to indicate the size of the immediate value supported. The shorthand notation Immed16|32|64 is sometimes used when different size immediate values are supported.
- Terms in brackets [ ] are required.
- Terms in braces { } are optional.
- Alternate terms are separated by a vertical bar |.
- The form R1 and R2 represent Operand 1 register and Operand 2 register respectfully, and can typically be any VM general-purpose register R0-R7.
- Within descriptions of the instructions, brackets [ ] enclosing a register and/or index indicate that the contents of the memory pointed to by the enclosed contents are used.

22.7 Instruction Encoding

Most EBC instructions take the form:

```
INSTRUCTION R1, R2 Index|Immed
```

For those instructions that adhere to this form, the binary encoding for the instruction will typically consist of an opcode byte, followed by an operands byte, followed by two or more bytes of immediate or index data. Thus the instruction stream will be:

```
(1 Byte Opcode) + (1 Byte Operands) + (Immediate data|Index data)
```

22.7.1 Instruction Opcode Byte Encoding

The first byte of an instruction is the opcode byte, and an instruction's actual opcode value consumes 6 bits of this byte. The remaining two bits will typically be used to indicate operand sizes and/or presence or absence of index or immediate data. The Table, below, *Opcode Byte Encoding* defines the bits in the opcode byte for most instructions, and their usage.

Table 22.6: Opcode Byte Encoding

Bit	Sym	Description
6..7	Modifiers	One or more of: Index or immediate data present/absent Operand size Index or immediate data size
0..5	Op	Instruction opcode

For those instructions that use bit 7 to indicate the presence of an index or immediate data and bit 6 to indicate the size of the index or immediate data, if bit 7 is 0 (no immediate data), then bit 6 is ignored by the VM. Otherwise, unless otherwise specified for a given instruction, setting unused bits in the opcode byte results in an instruction encoding exception when the instruction is executed. Setting the modifiers field in the opcode byte to reserved values will also result in an instruction encoding exception.

22.7.2 Instruction Operands Byte Encoding

The second byte of most encoded instructions is an operand byte, which encodes the registers for the instruction operands and whether the operands are direct or indirect. The Table below, *Operand Byte Encoding* defines the encoding for the operand byte for these instructions. Unless otherwise specified for a given instruction, setting unused bits in the operand byte results in an instruction encoding exception when the instruction is executed. Setting fields in the operand byte to reserved values will also result in an instruction encoding exception.

Table 22.7: Operand Byte Encoding

Bit	Description

continues on next page

Table 22.7 – continued from previous page

7	0 = Operand 2 is direct 1 = Operand 2 is indirect
4..6	Operand 2 register
3	0 = Operand 1 is direct 1 = Operand 1 is indirect
0..2	Operand 1 register

22.7.3 Index/Immediate Data Encoding

Following the operand bytes for most instructions is the instruction's immediate data. The immediate data is, depending on the instruction and instruction encoding, either an unsigned or signed literal value, or an index encoded using natural encoding. In either case, the size of the immediate data is specified in the instruction encoding.

For most instructions, the index/immediate value in the instruction stream is interpreted as a signed immediate value if the register operand is direct. This immediate value is then added to the contents of the register to compute the instruction operand. If the register is indirect, then the data is usually interpreted as a natural index (*NATURAL INDEXING*) and the computed index value is added to the contents of the register to get the address of the operand.

22.8 EBC Instruction Set

The following sections describe each of the EBC instructions in detail. Information includes an assembly-language syntax, a description of the instruction functionality, binary encoding, and any limitations or unique behaviors of the instruction.

22.8.1 ADD

Syntax:

```
ADD[32|64] {@}R1, {@}R2 {Index16|Immed16}
```

Description

Adds two signed operands and stores the result to Operand 1. The operation can be performed on either 32-bit (ADD32) or 64-bit (ADD64) operands.

Operation:

```
Operand 1 <= Operand 1 + Operand 2
```

Table 22.8: ADD Instruction Encoding

BYTE	Description	
0	Bit	Description

continues on next page

Table 22.8 – continued from previous page

	7	0 = Immediate/index absent 1 = Immediate/index present
	6	0 = 32-bit operation 1 = 64-bit operation
	0..5	Opcode = 0x0C
1	Bit	Description
	7	0 = Operand 2 direct 1 = Operand 2 indirect
	4..6	Operand 2
	3	0 = Operand 1 direct 1 = Operand 1 indirect
	0..2	Operand 1
2..3	Optional 16-bit immediate data/index	

Behaviors and Restrictions

- If Operand 2 is indirect, then the immediate data is interpreted as an index and the Operand 2 value is fetched from memory as a signed value at address [R2 + Index16].
- If Operand 2 is direct, then the immediate data is considered a signed immediate value and is added to the R2 register contents such that Operand 2 = R2 + Immed16.
- If the instruction is ADD32 and Operand 1 is direct, then the result is stored back to the Operand 1 register with the upper 32 bits cleared.

22.8.2 AND

Syntax

```
AND[32|64] {@}R1, {@}R2 {Index16|Immed16}
```

Description

Performs a logical AND operation on two operands and stores the result to Operand 1. The operation can be performed on either 32-bit (AND32) or 64-bit (AND64) operands.

Operation

```
Operand 1 <= Operand 1 AND Operand 2
```

Table 22.9: AND Instruction Encoding

BYTE	Description	
0	Bit	Description

Table 22.9 – continued from previous page

	7	0 = Immediate/index absent 1 = Immediate/index present
	6	0 = 32-bit operation 1 = 64-bit operation
	0..5	Opcode = 0x14
1	Bit	Description
	7	0 = Operand 2 direct 1 = Operand 2 indirect
	4..6	Operand 2
	3	0 = Operand 1 direct 1 = Operand 1 indirect
	0..2	Operand 1
2..3	Optional 16-bit immediate data/index	

Behaviors and Restrictions

- If Operand 2 is indirect, then the immediate data is interpreted as an index, and the Operand 2 value is fetched from memory as an unsigned value at address [R2 + Index16].
- If Operand 2 is direct, then the immediate data is considered a signed immediate value and is added to the register contents such that Operand 2 = R2 + Immed16.
- If the instruction is AND32 and Operand 1 is direct, then the result is stored to the Operand 1 register with the upper 32 bits cleared.

22.8.3 ASHR

Syntax

```
ASHR[32|64] {@}R1, {@}R2 {Index16|Immed16}
```

Description

Performs an arithmetic right-shift of a signed 32-bit (ASHR32) or 64-bit (ASHR64) operand and stores the result back to Operand 1

Operation

```
Operand 1 <= Operand 1 SHIFT-RIGHT Operand 2
```

Table 22.10: ASHR Instruction Encoding

BYTE	Description	
0	Bit	Description

continues on next page

Table 22.10 – continued from previous page

	7	0 = Immediate/index absent 1 = Immediate/index present
	6	0 = 32-bit operation 1 = 64-bit operation
	0..5	Opcode = 0x19
1	Bit	Description
	7	0 = Operand 2 direct 1 = Operand 2 indirect
	4..6	Operand 2
	3	0 = Operand 1 direct 1 = Operand 1 indirect
	0..2	Operand 1
2..3	Optional 16-bit immediate data/index	

Behaviors and Restrictions

- If Operand 2 is indirect, then the immediate data is interpreted as an index, and the Operand 2 value is fetched from memory as a signed value at address [R2+ Index16].
- If Operand 2 is direct, then the immediate data is considered a signed immediate value and is added to the register contents such that Operand 2 = R2 + Immed16.
- If the instruction is ASHR32, and Operand 1 is direct, then the result is stored back to the Operand 1 register with the upper 32 bits cleared.

22.8.4 BREAK

Syntax:

```
BREAK [break code]
```

Description

The BREAK instruction is used to perform special processing by the VM. The break code specifies the functionality to perform.

BREAK 0 - Runaway program break. This indicates that the VM is likely executing code from cleared memory. This results in a bad break exception.

BREAK 1 - Get virtual machine version. This instruction returns the 64-bit virtual machine revision number in VM register R7. The encoding is shown in the Tables, below, *VM Version Format* and *BREAK Instruction Encoding* . A VM that conforms to this version of the specification should return a version number of 0x00010000.

Table 22.11: VM Version Format

Bits	Description
63-32	Reserved = 0
31..16	VM major version
15..0	VM minor version

BREAK 3 - Debug breakpoint. Executing this instruction results in a debug break exception. If a debugger is attached or available, then it may halt execution of the image.

BREAK 4 - System call. There are no system calls supported for use with this break code, so the VM will ignore the instruction and continue execution at the following instruction.

BREAK 5 - Create thunk. This causes the interpreter to create a thunk for the EBC entry point whose 32-bit IP-relative offset is stored at the 64-bit address in VM register R7. The interpreter then replaces the contents of the memory location pointed to by R7 to point to the newly created thunk. Since all EBC IP-relative offsets are relative to the next instruction or data object, the original offset is off by 4, so must be incremented by 4 to get the actual address of the entry point.

BREAK 6 - Set compiler version. An EBC C compiler can insert this break instruction into an executable to set the compiler version used to build an EBC image. When the VM executes this instruction it takes the compiler version from register R7 and may perform version compatibility checking. The compiler version number follows the same format as the VM version number returned by the BREAK 1 instruction.

Table 22.12: BREAK Instruction Encoding

Byte	Description
0	Opcode = 0x00
1	0 = Runaway program break 1 = Get virtual machine version 3 = Debug breakpoint 4 = System call 5 = Create thunk 6 = Set compiler version

Behaviors and Restrictions

- Executing an undefined BREAK code results in a bad break exception.
